In spite of its situation in the centre of the archipelago, Celebes possesses a fauna of a very distinctive kind. The number of species is small; but in many cases they are peculiar to the island. Of the birds, for example, about 200 species are known; and of these no fewer than 80 are peculiar. The mammalian species number only 14, and of these 11 belong almost entirely to the Celebesian area. Most remarkable are the *Macacus niger*, an ape found nowhere else but in Batchian; the *Anoa depressicornis*, a small ox-like quadruped, which inhabits the mountainous districts; and the babirusa or pig-deer of the Malays. There are no large beasts of prey, and neither the elephant, the rhinoceros, nor the tapir is represented. Wild-buffaloes, swine, and goats are pretty common; and most of the usual domestic animals are kept in greater or smaller numbers. Though they receive but little attention, the cattle are good. The horses are in high repute in the archipelago; formerly about 700 were yearly exported to Java, but the supply has considerably diminished.

The same peculiarity of species holds in regard to the insects of Celebes as to the mammals and birds. Out of 118 species of butterflies, belonging to four important classes, no fewer than 86 are peculiar; while among the rose-chafers or *Cetoniidae* the same is the case in 19 out of 30. Equally remarkable with this presence of peculiar species is the absence of many kinds that are common in the rest of the archipelago; and the fact that similarities are often to be traced with species belonging to Africa and other remote regions is highly suggestive.

Vegetation is, it need hardly be said, extremely rich; but there are fewer large trees than in the other islands of the archipelago. Of plants that furnish food for man the most important are rice, maize, and millet, coffee, the cocoa-nut tree, the sago-palm, the obi or native potato, the bread-fruit, and the tamarind; with lemons, oranges, mangosteens, wild-plums, Spanish pepper, beans, melons, and sugar-cane. The shaddock is to be found only in the lower plains. Indigo, cotton, and tobacco are grown; the bamboo and the ratan-palm are common in the woods; and among the larger trees are sandal-wood, ebony, sapan, and teak. The gemuti palm furnishes fibres for ropes; the juice of the *Arenga saccharifera* is manufactured into sugar and a beverage called sagueir; and intoxicating drinks are prepared from several other palms.

Except where Dutch influence has made itself felt, very little attention has been paid by the native races to any agricultural pursuit; and their manufacturing industries are few and limited. The weaving of cotton cloth is principally carried on by women; and the process, at least for the finer description, is tedious in the extreme. The cheap introduction of European goods is gradually lessening the amount of native stuffs. The houses are built of wood and bamboo; and as the use of diagonal struts has not been introduced, the walls soon lean over from the force of the winds. The most important of the mineral pro-

ducts of the island are gold and salt; excellent iron is also found, which is utilized by the natives; and coal of rather poor quality has been met with in various places, as in the district of Maros. The gold-mines are mainly in the northern peninsula; but even there the amount actually obtained is not so great as it was formerly. The various chiefs, bound by contract to bring yearly a fixed quantity of the metal to the Dutch authorities, frequently fail in their engagements, and many of them have been of necessity exempted. The gold is usually found at a depth of from 12 to 75 feet; but there are some mines in Bwool and Tontoli that reach 90 feet. In many, such as those of Ankahulu, Pagiana, and Popasatu, it is very cold, and the miners have to sit all day in nitrous water.

The whole island is practically in the hands of the Dutch Government, though a comparatively small portion is under their direct administration, and a large number of petty princes are still permitted to do very much as they please in the internal management of their territories. For administrative purposes it is distributed among the residencies of Celebes, Manado, and Ternate, of which the two former belong solely to the island, while the third includes a large part of the Moluccas.

Residency
of Celebes.

The residency of Celebes, formerly known as the Government of Macassar, comprises all the various states that surround the Gulf of Boni, and is divided into the following departments:—(1) Macassar, (2) the Northern Districts, (3) the Southern Districts, (4) Bulecomba and Bonthain, and (5) Saleyer and the subordinate islands, Buton, Sumbawa, and Bima.

The department of Macassar, or Mangkasara as it is called in the native language, is one of the oldest parts of the Dutch possessions. It contains Macassar, the capital of the residency, which is situated on the west coast of the southern peninsula in 5° 7' 45" S. lat., forms one of the principal ports in the archipelago, and has a population of from 15,000 to 20,000. The inhabitants of the department consist mainly of Macassars and Malays proper, Endinese from the Island of Flores, and immigrants from the neighbouring kingdom of Wadjo. The foreign colonies are each under the management of a separate captain, and the Malays are also under the care of a head priest. The Macassars proper are one of the most important peoples in the island. They belong to the Malay race, are well built and muscular, and have in general a "dark-brown complexion, a broad and expressive face, black and sparkling eyes, a high forehead, a flattish nose with large alæ, a large mouth, and black soft hair, which they let fall over their shoulders." The women are sprightly, clever, and amiable, and in former times were bought for large prices. The men are brave and not treacherous, but ambitious, jealous, and extremely revengeful. Drunkenness is rare, but to gambling and cock-fighting they are passionately addicted; and so frequent among them is the running amuck that the Dutch authorities had to dismiss the Macassar soldiers from their service. In all sorts of bodily exercises, as swinging, wrestling, dancing, riding, and hunting, they take great pleasure. Though they call themselves Mahometans, their religion is largely mingled with pagan superstitions; they worship animals, and a certain divinity called Karaeng Lové, who has power over their fortune and health. Their language, which belongs to the Malayo-Javanese group, is spoken by about 300,000 persons, in Macassar proper, Goa, Tello, Sanraboni, Turateya, Bulecomba, Tanralili, and a great many parts of the southern peninsula; but it has a much smaller area than the Buginese, which is the language of Boni. It is very deficient in generalizations; thus, for example, it has words for the idea of carrying in the hand, carrying on the head, carrying on the shoulder, and so on, but has no word for the notion of simply carrying. It has

adopted a certain number of vocables from Sanskrit, Malay, Javanese, and Portuguese, but on the whole is remarkably pure, and has undergone comparatively few changes in the course of the last two or three centuries. It is written in a peculiar character, which has displaced, and probably been corrupted from, an old form employed as late as the 17th century. Neither bears any trace of derivation from the Sanskrit alphabet. The priests affect the use of the Arabic letters. The literature is very poor, and consists largely of romantic stories from the Malay, and religious treatises from the Arabic. Of the few original pieces the most important are the early histories of Goa, Tello, and some other states of Celebes, and the *Rapang*, or collection of the decrees and maxims of the old princes and sages. The more modern productions are letters, laws, and poems, many of the last having very considerable beauty. For his knowledge of the Macassar the European scholar is mainly indebted to the labours of B. F. Malthes of the Dutch Bible Society, who was sent out in 1846, and has published *Makassaarsche Spraakkunst* (1858), *Makassaarsch-Hollandsch Woordenboek* (1859), *Ethnographische Atlas* (1859), *Makassaarsche Chrestomathie* (1860), and various communications to the *Zeitsch. der morgenl. Gesellsch.*

The department of the Northern Districts, called also Maros (properly Marusa), from the chief town, lies to the north of Macassar, and is divided into twenty-six districts. It is watered by the River Maros, which has a channel of great picturesqueness broken by waterfalls and bordered by caves. The mineral products comprise gold, marble, porcelain-clay, and anthracite; but the extensive rice-fields are the principal source of wealth. The river is commanded by the fort of Valkenburg; and a great road, constructed in 1859, leads through the department. About five miles from the town are the warm mineral springs of Amarang and Magemba. The population is estimated at 120,000. The prevailing language is Buginese, but Macassar is also spoken by a considerable number.

The department of the Southern Districts, or Takalla, lies to the south-west of Macassar, and is divided into two parts by the interposition of the little independent state of Sanraboni. The population is estimated at 70,000, and the language is Macassar. The people of the district of Glissong or Galesong are remarkable for their attachment to a seafaring life. In 1863 the department was increased by the annexation of Turateya, which included the three small states of Bintamo, Bangkala, and Laikan, previously troublesome by their piracies and raids. The Turateyans speak a mixture of Macassar and Buginese.

Separated from Turateya by the River Tino is the department of Bonthain and Bulecomba, a thinly-peopled and mountainous country, chiefly remarkable for the lofty summit of Lompobattang or Dikbnik, more familiarly known as the Peak of Bonthain, which has a height of about 11,000 feet. The soil is specially adapted for the culture of coffee. The inhabitants are peaceful and well-behaved, but in education and civilization they are less advanced than those of the departments already described. They were formerly subordinate to the Macassar kingdom.

To the north of these two states lies the important kingdom of Boni, of which an account will be found in a separate article (vol. iv. p. 32), and to the north of Boni, and separated from it by the River Chinrana, is the rival kingdom of Wajo or Wadjo, with a coast line of about 50 miles along the Gulf of Boni. It is governed by about forty chiefs or nobles, who are almost independent in their respective districts and maintain their individual bands of followers, but at the same time recognize the overlordship of the prince. The different offices of the state are not unfrequently held by women; and the greatest importance is attached to purity of descent. The inhabitants rather

neglect the culture of the soil; and large numbers of them resort to the neighbouring states as traders. The capital was formerly Tesora or Tossora, a large straggling city near the River Chintana, embracing within its fortifications a space of several miles in circuit. For numerous details on this district the reader may consult Mundy's *Narrative of Events in Borneo and Celebes*, vol. i.

To the south-west of Wadjo is the kingdom of Sopeng, which was long connected by intermarriages with Boni. The ground is very fruitful, and large quantities of rice are exported. The capital was formerly a place of the same name on the coast; but the rajah removed his residence to Sengkang on Lake Tempe. Sopeng recognized the Dutch supremacy in 1825. The population is estimated at 18,000.

To the north of Sopeng lies the territory of Adja Tamkarang, under the government of the prince of Lidenring, who takes his title from a small principality of that name. It is traversed by the Sadang River, one of the most important of those that flow into the Strait of Macassar.

Round the head of the Bay of Boni stretches the kingdom of Luvu (Loewoe), a well-peopled district, productive of gold and excellent iron, but greatly depressed by an unsatisfactory government. To the south-west of Luvu lie the districts of Ussu and Lellewan, and south of these the state of Baikouka or Minkoko, with its capital Pansulai on the Gulf of Boni; but the whole of this region is comparatively unexplored. The Minkokos have a considerable resemblance to the Dyaks of Borneo, and maintain a similar custom of head-hunting. Their language is akin to Buginese.

At the very end of the eastern peninsula is situated the district of Polean Rumbia, continuous on its north-east boundary with the more important territory of Lavui, which stretches along the coast of the Bay of Tolo, and is tributary to the king of Boni. The latter district possesses in Kendari or Vosmaer's Bay one of the finest harbours in the archipelago, and it carries on a certain amount of traffic. The coast is frequented by numbers of the Bajows.

The rest of the lands that lie round the Bay of Tolo belong to the residency of Ternate. Continuous with Lavui is the principality of Tombuku, a densely-wooded, and partially-explored territory, governed by an hereditary chief under the sultan of Ternate. The population is mainly settled in the interior, and their numbers were estimated in 1852 at 15,000. They have no regular coin, and strips of cotton cloth are used in exchange. Their language seems to have almost no connection with any other in the archipelago. Among the people along the coast excellent workers in metal are found, and earthenware is also manufactured. The capital was formerly Lanona; but since 1856 this honour belongs to Sabita. At the very head of the bay is the district of Tomore or Tomaiki, with a river of the same name; while along the northern side are situated the territories of Bangay and Balante. From the latter iron and timber are exported.

The country that lies round the Gulf of Gorontalo belongs to the residency of Manado, and is divided into the Minahassa or Confederation of Manado, the department of Gorontalo, and various states, such as Parigi, Bwool, and others that will be mentioned in the course of the article.

Of these the most important, is the Minahassa, or properly Ni-mahassa, of Manado, which derives its name from the union of thirty-six states under the Dutch supremacy to resist the claims of the king of Bolang, who had made himself at one time master of the district. It occupies the most eastern part of the northern peninsula, and is divided into the five departments of Manado, Kema, Tondano, Anurang, and Bolang. Of the whole island it is the most distinctly volcanic portion, and contains several mountains that have been in active eruption within modern

times. The most important summits are those of Klabat (6560 feet high), Saputan (5960), Engerong (4050), Lokou (5240), Prumangan or Mahabu (4300), Kimavang, and Papelampungan. In 1806 the Mountain Tonkoko threw forth a quantity of ashes and pumice-stone that darkened the air for two days and covered the ground for many miles with a layer an inch thick. There are numerous boiling springs and geysers, the most interesting being Lahendaug, where the Count Charles de Vidua de Conzano met with his death in 1830. An interesting account of a visit to several of these volcanic phenomena is given by Mr Bickmore in his *East Indian Archipelago*. Perhaps in no part of their possessions have greater and happier transformations been effected by the Dutch than in this district. In the beginning of this century the inhabitants were still savages, broken up into numerous tribes that were almost never at peace with each other, and speaking such a variety of dialects that hardly any village was quite intelligible to its neighbours. About 1822 it was discovered that the soil of the mountain sides was fitted for the growth of coffee; the cultivation was introduced and a system established which stimulated the native chiefs to undertake the management of the plantations. The result has been not only to make the Minahassa one of the best coffee districts in the archipelago, but to advance the civilization of the inhabitants in a wonderful manner. Missions have been established by the Dutch Missionary Society, and have met with the most encouraging success. In 1859 the mission schools numbered 102, and were attended by 8996 pupils; while at the same time 12 Government schools had 1049 pupils and 28 village schools had 1610. The various local dialects are rapidly being replaced by Malay, which is the language adopted for educational purposes. The villages, which have grown up in considerable numbers, are neat and tidy, and most of the houses are well built; the country is traversed by good roads, finely-shaded with trees and in many cases fit for carriages; and bridges have been erected over the rivers. The trade of the district is in a flourishing condition and promises to become more important. The principal articles are the coffee, cocoa, rice, and trepang. In 1858 the number of households employed in the coffee-culture was 12,909; the number of trees in regular gardens was 3,449,518; and their produce for the year amounted to 22,866 piculs. Since that date the plantations both of the Government and private speculators have very largely increased. The plant succeeds admirably at a height of from 1500 up to 4000 feet above the sea, and produces a fine kernel of a translucent greenish blue colour, which is known in the market as Manado coffee, and brings a much higher price than the Java growth. Cocoa was probably introduced by the early Spanish navigators, but it received little attention till about 1822, when some Dutch and Chinese settlers undertook its cultivation. Since that time it has become a pretty important article, and has been introduced into Gorontalo and the Sangir Islands; but the crop is unfortunately a somewhat precarious one. The koffo or Manilla-hemp (*Musa textilis*) is largely grown, more especially in the neighbourhood of Amurang, where the Government has established a rope factory. The nutmeg, though only introduced in 1853, is now cultivated pretty extensively. Tobacco is also grown, but mainly for home consumption. The best is obtained from the district of Bantek. The population of the Minahassa was, in 1868, 105,514.

The department of Gorontalo comprises the various districts of Gorontalo, Limbotto, Bone, Bintauna, Suvava, Bolango, Attingola, Bualemo, Muton, Parigi, Sausu, Posso, Tongko, Todjo, and the Togian Islands. Gorontalo proper lies on the north of the Tomini Bay. The inhabitants are mainly Mahometan Malays, and they possess

about 200 Mahometan priests, most of whom can neither read nor write. The capital is a large and flourishing town with considerable trade; it has a Dutch garrison and fort, and a Christian school. The rivers and lake furnish abundance of fish, and almost every house has a pond attached for keeping those captured alive. Limbotto, a small state of about 6000 inhabitants, since 1865 under Dutch direction, is chiefly noticeable for the Bay of Kwandang and the gold-mines of Limbotto, Bulatu, and Sulametta. Mutou possesses several gold-mines. The village of that name lies in $0^{\circ} 23' N.$ lat. and $121^{\circ} 30' 18'' E.$ long. Along the northern coast to the north of Mutou lie the states of Palele, Bwool, and Tontoli, of which the second is the most important, being traversed by one of the largest rivers in the island, and possessing valuable gold-mines and great numbers of sago-palms. The composition of its population in 1870 was (according to J. G. F. Riedel in the *Tijdschrift voor Indische Taal-, Land-, en Volkenkunde*, 1874) 4229 natives, 726 from Gorontalo and Limbotto, 466 from Kayeli, 230 Buginese, 84 Tontoli, 38 Mandharese, and 22 Arabs. Tontoli was formerly the resort of pirates, but in 1822 it was cleared by Captain De Man.

Along the south side of the Bay of Gorontalo stretches the country of Parigi from Amphibabu to the River Dulagu. It has a very fertile territory, and a considerable trade is carried on with Palos and Dongala, the districts on Tomini Bay, and Singapore. The exports are gold, horses, coconuts, bananas, and a kind of resin called damar. Parigi recognized the Dutch supremacy in 1850, but has preserved its autonomy, and is governed by a prince and several chiefs. The principal village is Parigi di Atas.

On the west coast of the island, and forming as it were the nucleus from which the peninsulas spring, lie the districts of Dongala, Palos, and Kayeli. Dongala is situated on the Bay of Palos, and is governed by a rajah who recognized Dutch supremacy in 1824. Palos is governed by an independent chief, and is in a flourishing condition. The town is situated in $0^{\circ} 57' S.$ lat. and $119^{\circ} 34' E.$ long., and is connected by road with Parigi and Boni. Its inhabitants carry on an active trade both by sea and land. The kingdom of Kayeli was at one time under the sultan of Ternate, passed by conquest to the people of Macassar, was restored to the sultan by the treaty of Bouga, and was by him presented to the Dutch, whose authority was only recognized in 1854. The soil is well fitted for cultivation, and yields coffee and cocoa-nuts for export. The kingdom of Maudhar lies further south, and is governed by seven chiefs, who take their titles from the seven principal rivers, and till 1854 recognized the supremacy of Boni. The inhabitants speak a distinct language. Those on the coast are nominal Mahometans, those inland are still pagau. They are active traders, and take voyages to Java, Beneoolen, Malacca, Singapore, and Manilla. Toradja, which lies further inland, is possessed by a wild pagan race, who keep themselves apart from all intercourse, and are generally regarded as the original inhabitants of the island.

Celebes was first discovered by the Portuguese in the early part of the 16th century, the exact date assigned by some authorities being 1512. The name does not appear to be of native origin, and the plural form is probably due to the belief that the different peninsulas were so many separate islands. At the time of the Portuguese discovery, the Macassars were the most powerful people in the island, having successfully defended themselves against the king of the Moluccas and the sultan of Ternate. In 1609 the English attempted to gain a footing. At what time the Dutch first arrived is not certainly known, but it was very probably in the end of the 16th or beginning of the 17th century, since in 1607

they formed a connection with Macassar. In the year 1611 the Dutch East Indian Company obtained the monopoly of trade on the Island of Buton; and in 1618 an insurrection in Macassar gave them an opportunity of obtaining a definite establishment there. In 1660 the kingdom was finally subjugated by Van Dam and Truitman, with a fleet of 33 ships and a force of 2700 men. In 1666 the war broke out anew; but it was brought to an end by Speelman in the following year, and the treaty of Bouga or Banga was signed, by which the Dutch were recognized as the protectors and mediators of the different states who were parties to the treaty. In 1683 the north-eastern part of the island was conquered by Robert Paddenburg, and placed under the command of the governor of the Moluccas. In 1703 a fort was erected at Mauado. The kingdom of Boni was successfully attacked by Van Geen in 1824, and in August of that year the Bouga treaty was renewed in a greatly modified form. Since then the principal military event is the Boni insurrection, which was quelled in 1859. With the exception of Manado, the Dutch settlements in Celebes have not been financially successful; but as the resources of the country are developed it will, doubtless, become a very valuable possession.

In Veth's *Woordenboek van Nederlandsch Indië* there will be found an extensive bibliography of Celebes drawn up by H. C. Millies. Besides the well-known works of Valentyn, Stavorinus, Raffles, and Crawford, it will be sufficient to mention Van den Bosh, *Nederlandsche Bezittingen in Azia, &c.*, 1818; Vincent, "Notice sur l'île de Celebes," in *Journ. des Voyages*, 1826; Olivier's *Reizen*, 1834; Reinwardt's *Reis naar het Oostelijk gedeelte van den Ned. Archipel*, in 1821, 1858; Van der Hart, *Reize rondom het Eiland Celebes*, 1853; Samuel White, *Account of the last rebellion at Macassar*, 1687; Stubenvoll's *Translation of History of the Island of Celebes*, by Mr R. Blok, Gov. of Macassar, 1817; Capt. R. Mundy, *Narrative of Events in Borneo and Celebes*, 1848; Ed. Dulaurier, *Code Maritime des Royaumes Mangkassar et Bougui*, 1845; Wallace, *Malay Archipelago*, 1869; Bickmore, *East Indian Archipelago*, 1868; Veth's *Een Nederlandsch reiziger op Zuid Celebes*, 1875; Riedel's *Het landschap Bocool, Noord Celebes*, 1872; the same writer's "Die landschaften Holontalo, Limoeto," &c. in the *Zeitschr. für Ethnologie*, 1871; Beccari's "Viaggio" in Guido Cora's *Cosmos* for 1874-6. (H. A. W.)

CELERY (*Apium graveolens*), a biennial plant belonging to the Natural Order *Umbelliferae*, which, in its native condition, is known in England as snallage. In its wild state it is common by the sides of ditches and in marshy places, especially near the sea, producing a furrowed stalk and wedge-shaped leaves, the whole plant having a coarse, rank taste, and a peculiar smell. By cultivation and blanching the stalks lose their aerial qualities and assume the mild sweetish aromatic taste peculiar to celery as a salad plant. The plants are raised from seed, sown either in a hot bed or in the open garden, according to the season of the year, and after one or two thinnings out and transplantings, they are, on attaining a height of 6 or 8 inches, planted out in deep trenches for convenience of blanching, which is effected by earthing up and so excluding the stems from the influence of light. A large number of varieties are cultivated by gardeners, which are ranged under two classes, white and red,—the white varieties being generally the best flavoured, and most crisp and tender. As a salad plant, celery, especially if at all "stringy," is difficult of digestion, but it possesses valuable diuretic properties. Both blanched and green it is stewed and used in soups, the seeds also being used as a flavouring ingredient. In the south of Europe celery is seldom blanched, but is much used in its natural condition.

Celeriac is a variety of celery cultivated more on account of its roots than for the stalks, although both are edible and are used for salads and in soups. It is chiefly grown in the north of Europe, and is not in much request in Great Britain.

CELESTINE, the name of five popes.

CELESTINE I. was a Roman, and is supposed to have been a near relative of the Emperor Valentinian. Various portions of the liturgy are attributed to him, but without any certainty on the subject. He held the Council of Ephesus in which the Nestorians were condemned, in 431. Four letters written by him on that occasion, dated all of them 15th March 431, together with a few others, to the African bishops, to those of Illyria, of Thessalonica, and of Narbonne, are extant in retranslations from the Greek, the Latin originals having been lost. He actively persecuted the Pelagians, and was zealous for Roman orthodoxy. He sent Palladius, a Greek, to Scotland, and Patricius (St Patrick) to Ireland. He raged against the Novatians in Rome, imprisoning their bishop, and forbidding their worship. He was zealous in refusing to tolerate the smallest innovation on the constitutions of his predecessors, and is recognized by the church as a saint. He occupied the seat of St Peter eight years five months and three days, and died on the 6th April 432. He was buried in the cemetery of St Priscilla in the Via Salaria, but his body, subsequently moved, lies now in the Church of St Prasside.

CELESTINE II. was elected in 1143, governed the church only five months and thirteen days, died 9th March 1144, and was buried at the Lateran. His name had been Guido di Castello, from the small town of which he was a native. He had studied under Peter Abelard. The principal act of his Papacy was the absolution of Louis VII. of France at the request of that penitent monarch, and the removal of the interdict under which that country had lain for three years.

CELESTINE III., Giacinto Bobonc Orsini, of that noble race, was elected Pope 30th March 1191, being then only a deacon, received priest's orders on the 13th of April, ruled the church six years, nine months, and nine days (though believed to have been ninety when elected), died 8th January 1198, and was buried at the Lateran. He crowned the Emperor Henry VI. on the day after his election with a ceremonial symbolizing his absolute supremacy, as described by Roger Hoveden, who is believed (more reasonably as it would seem) by Baronius, but discredited by Natalis Alexander. He subsequently excommunicated the same Henry for wrongfully keeping Richard of England in prison. In 1192 he confirmed the statutes of the Teutonic Order of Knights. He would have resigned the Papacy, and recommended a successor shortly before his death, but was not suffered to do so by the cardinals.

CELESTINE IV., Godfrey Castiglioni of Milan, a nephew of Urban III., became a monk at Hautecombe in Savoy, there wrote a history of Scotland, and was elected Pope by seven cardinals only, in the midst of troubles caused by the vicinity and violence of the Emperor Frederick II., on the 22d September 1241. He occupied the throne only seventeen days, died, before consecration, on the 8th October 1241, and was buried at the Vatican.

CELESTINE V. was known before his election as Peter di Morone. Born in 1215, the son of a peasant in the Neapolitan district, named Angelario, he became a Benedictine monk at Faifoli in the diocese of Benevento when he was seventeen. He showed from the first an extraordinary disposition to asceticism and solitude, and in 1239 retired to a solitary cavern on the mountain Morone, whence his name. Five years later he left this retreat, and betook himself, with two companions, to a similar cave on the Mountain of Majella in the Abruzzi, where he lived as strictly as was possible according to the example of St John the Baptist. Terrible accounts are given of the severity of his penitential practices. While living in this manner he founded, in 1244, the order sub-

sequently called after him Celestines. (See CELESTINES.) The cardinals assembled at Perugia after the death of Nicholas IV., and after long dissensions and difficulties agreed as a means of escaping from them to elect the hermit Pietro di Morone. When sent for he obstinately refused to accept the Papacy, and even, as Petrarch says,¹ attempted flight, till he was at length persuaded by a deputation of cardinals accompanied by the kings of Naples and Hungary. Elected 7th July 1294, he was crowned in the city of Aquila in the Abruzzi, 29th August. He issued two decrees,—one confirming that of Gregory X., which orders the shutting of the cardinals in conclave; the second declaring the right of any Pope to abdicate the Papacy,—a right he, at the end of five months and eight days, proceeded himself to exercise at Naples on the 13th December 1294. He did one other thing which may be noted, because it seems to be the only instance known to the church in which such a thing occurred. He empowered one Francis of Apt, a Franciscan friar, to confer priest's orders on Lodovico, son of Charles, king of Sicily,—a fact which seems to have escaped the notice of Bingham; who says that such a thing was never done.² In the formal instrument of his renunciation he recites as the causes moving him to the step, "the desire for humility, for a purer life, for a stainless conscience, the deficiencies of his own physical strength, his ignorance, the perverseness of the people, his longing for the tranquillity of his former life;" and having divested himself of every outward symbol of dignity, he retired to his old solitude. He was not allowed to remain there, however. His successor, Boniface VIII., sent for him, and finally, despite desperate attempts of the late Pope to escape, got him into his hands, and imprisoned him in the castle of Fumone near Ferentino in Campagna, where, after languishing for ten months in that infected air, he died on the 19th May 1296. He was buried at Ferentino, but his body was subsequently removed to Aquila. Many Dantescan commentators and scholars have thought that the poet stigmatized Celestine V. in the enigmatical verse which speaks of him "*Che fece per viltate il gran rifiuto*."³ Recent opinion on the point more reasonably rejects this interpretation. Celestine V., like the first of the name, is recognized by the church as a saint.

CELESTINES, a branch of the great Benedictine monastic order. At the foundation of the new rule, they were called Hermits of St Damiano, or Moronites (or Murronites), and did not assume the appellation of Celestines till after the election of their founder to the Papacy as Celestine V. The fame of the holy life and the austerities practised by that saintly hermit (as noticed above) in his solitude on the Mountain of Majella, near Sulmona, attracted many visitors, several of whom were moved to remain and share his mode of life. They built, therefore, a small convent on the spot inhabited by the holy hermit, which very shortly became too small for the accommodation of those who thronged thither to share their life of privations. Peter of Morone, their founder, therefore built a number of other small oratories in that neighbourhood. This happened about the year 1254. A new religious community was thus formed, and Peter of Morone gave them a rule formed in accordance with his own practices. In 1264 the new institution was approved by Urban IV. But the founder, having heard that it was probable that Pope Gregory X., then holding a council at Lyons, would suppress all such new orders as had been founded since the Lateran Council, having commanded that such institutions should not be further multiplied, betook himself to Lyons,

² *Orig. Eccl.*, lib. ii. cap. 3, sec. 5.

³ "Who made from cowardice the great refusal," *Inferno*, canto iii. line 60.

and there succeeded in persuading Gregory to approve his new order, constituting it a branch of the Benedictines, with a rule based on that of St Benedict, but adding to it many additional severities and privations. Gregory further took it under the Papal protection, assured to it the possession of all property it might acquire, and endowed it with that great and constant, but most pernicious and fatal, object of the ambition of all monastic orders, exemption from the authority of the ordinary. Nothing more was needed to ensure the rapid spread of the new association; and Peter the hermit of Morone lived to see himself "Superior-General" of thirty-six monasteries and more than six hundred monks. Peter, however, cannot be accused of ambition or the lust of power when a monastic superior, any more than when he insisted on divesting himself of the Papacy, to which he was subsequently raised. As soon as he had seen his new order thus consolidated he gave up the government of it to a certain Robert, and retired once again to a still more remote solitude to give himself up more entirely to solitary penance and prayer. Shortly afterwards, in a chapter of the order held in 1293, the original monastery of Majella being judged to be too desolate and exposed to too rigorous a climate, it was decided that the monastery which had been founded in Sulmona should be the headquarters of the order and the residence of the General-Superior, as it has continued to be to the present day. The next year Peter the hermit of Morone, having been, despite his reluctance, elected Pope by the name of Celestine V., the order he had founded took the name of Celestines. The hermit Pope found time in the few short months of his Papacy to confirm the rule of the order, which he had himself composed, and to confer on the society a variety of special graces and privileges. In the only creation of cardinals promoted by him, among the twelve raised to the purple, there were two monks of his order. He found time also to visit personally the great Benedictine monastery on Monte Casino, where he succeeded in persuading the monks to accept his more rigorous rule. He sent fifty monks of his order to introduce it, who remained, however, for only a few months.

After the death of the founder the order was favoured and privileged by Benedict XI., and rapidly spread through Italy, Germany, Flanders, and France, where they were received by Philip the Fair in 1300. Subsequently the French Celestines, with the consent of the Italian superiors of the order, and of Pope Martin V. in 1427, obtained the privilege of making new constitutions for themselves, which they did in the 17th century in a series of regulations accepted by the provincial chapter in 1667. At that time the French congregation of the order was composed of twenty-one monasteries, the head of which was that of Paris, and was governed by a Provincial with the authority of General. Paul V. was a notable benefactor of the order. But in consequence of later political changes and events the order has been dissolved.

According to their special constitutions the Celestines were bound to say matins in the choir at two o'clock in the morning, and always to abstain from eating meat, save in illness. The specialities of their rule with regard to fasting would be long and tedious to recount. It cannot be said that they are more severe than those of sundry other congregations, though much more so than is required by the old Benedictine rule. But in reading their minute directions for divers degrees of abstinence on various days, it is impossible to avoid being struck by the conviction that the great object of the framers of these rules, beyond the general purpose of ensuring an ascetic mode of life, was to create a speciality, to make a distinguishing difference between what "our" order does and what others do.

The Celestines wore a white woollen cassock bound with

a linen band, and a leathern girdle of the same colour, with a scapulary unattached to the body of the dress, and a black hood. It was not permitted to them to wear any shirt save of serge. Their dress in short was very like that of the Cistercians. But it is a tradition in the order that in the time of the founder they wore a coarse brown cloth. The church and monastery of St Pietro in Montorio originally belonged to the Celestines in Rome; but they were turned out of it by Sixtus IV. to make way for Franciscans, receiving from the Pope in exchange the Church of St Eusebius with the adjacent mansion for a monastery.

The order of Celestines has had its special historians, as Becquet, author of a history of the Celestines of France (Paris, 1719), and in the great collection of the Bollandists, vol. iii., under the month of May. But the order does not seem to have been fruitful of men of much mark; nor has it ever attained in the annals of Europe, or even of the church, a position of such importance as most of its rival societies have reached.

CELIBACY is the condition of those who are living a single life. The word is derived from *cælebs*, which means, not necessarily, as is very commonly supposed, a bachelor, but one who has no existing wife, whether he be a bachelor or a widower. (For authorities on this point, see Faccioliati, *Totius Latinitatis Lexicon*.) Scaliger and Voss derive the word from *κοίτη*, a bed, and *λείπω*, to leave. Some more fanciful etymologists, imagining that *cælebs* leads a celestial life, have suggested a derivation from *cælum*. The word is sometimes written *cælebs*, but the better authorities are in favour of the diphthong *æ*.

From the remotest times, those who have given their attention to the study of the conditions of human life in this world have deemed the married state to be a better thing both for the individual and the society to which he belongs than celibacy; while from an equally early period those who have professed to understand man's destinies in a future world, and the most proper means of preparing for them, have, though in no wise condemning marriage, conceived that celibacy is the better, purer, nobler, and higher condition of life. Lawgivers, sociologists, statesmen, philosophers, and physiologists have held the former view; devotees, ascetics, priests, the latter.

The lawgivers of various countries and ages have striven to discourage celibacy, as far as it was in the power of law to do so. The mention by Dionysius of Halicarnassus of an ancient law by which all persons of mature age were obliged to marry, may be cited. More authentic is the Roman law of the time of Augustus known as the *Lex Julia de maritandis Ordinibus*. It was afterwards called *Papia Poppæa*, or *Julia Papia*, from some new sanctions and amendments under the consuls Papius and Poppæus. Modern legislation has with increased wisdom shrunk from such direct attempts to coerce those subjected to it. But various provisions have in many European countries been enacted or proposed with the view of favouring the prevalence of marriage.

Any endeavour to give a satisfactory account of the investigations of physiologists, as bearing on this subject would lead us too far afield into the discussion of topics which fall more conveniently and appropriately under other headings. But it appears from recent statistics that married persons,—women in a considerable but men in a much greater degree,—have at all periods of life a greater probability of living than the single.

The ideas which, in the absence of or in opposition to the deductions of social philosophers and legislators, have found expression in the religious or ecclesiastical observances and theories of various ages and creeds, require and are fitted to be treated, though with the utmost brevity, in a somewhat more historical manner. Beausobre, in his *Histoire Critique du Manichéisme*, lib. vii. cap. 3, shows

that it was a prevalent opinion among the earliest Christians that if Adam had not fallen by disobedience, he would have lived for ever in a state of virgin purity, and that a race of sinless beings would have peopled Paradise, produced by some less objectionable means than the union of the first pair of mortals. Marriage was considered by them as a consequence of the Fall, the brand of the imperfection it had entailed, and a tolerated admission of an impure and sinful nature. To abstain from it, therefore, was the triumph of sanctity and at the same time the proof and the means of spiritual perfection. The earliest aspirants to this perfection among the Christians were not ecclesiastics as such, but hermits and anchorites, who adopted this among other means of attaining to recognized exceptional sanctity. It is not true, as is often stated, that the official expositors of Romanist theology and ecclesiastical law maintain that a vow of perpetual celibacy was required as a condition of ordination in the earliest ages of the church. It is fully admitted by them that, "although celibacy is preferable to matrimony, the divine law does not make it necessary for the reception of holy orders, or forbid either the ordination of married men or the marriage of those already in orders." In fact it would be impossible to maintain the reverse without denying the truth of many portions of ecclesiastical history, which the church cannot afford to spare, as to the conduct and lives of many of the early bishops, confessors, and martyrs, and without running very serious risk of damaging the favourite claim of the church to uninterrupted apostolical succession.

It was proposed in the second Council of Carthage (251) that celibacy should be required in candidates for the priesthood; but it cannot be pretended that even from that time it was always considered necessary. Moroni (*Dict. Storico Eccles.*, vol. ii. p. 58) makes a very much modified statement:—"As regards the usage and laws of the church," he says, "it has never been permitted to priests or to bishops to take wives, *when they had declared* at the time of their ordination that they would persevere in celibacy." It must be observed, however, with regard to the citations of the cases of bishops and priests of the early Greek Church, that Romanist ecclesiastical writers have never pretended that the practice of the Greek Church was not much more lax in this respect than that of the Latin or Western Church. The difference between the discipline of the one and the other was this. In the Greek Church no objection was made to the ordination of married men purposing to continue living with their wives, if these wives were their first wives, and had not before their marriage been widows; whereas, as is claimed by Romanist writers, in the Latin Church neither priests' nor bishops' orders were ever conferred on married men without requiring from them and from their wives reciprocal consent, and a solemn promise, that they would live separately during the remainder of their lives. As regards *bishops*, however, the practice in the Greek Church was the same as in the Latin. The decrees of various councils, however, show that the practice of the Greek Church in this respect was by no means settled and uniform. That of Ancyra in 313 permitted marriage only to such deacons as had protested against accepting the obligation of celibacy at the time of their ordination. The Council of Nice thought that the ancient tradition of the church should be re-established in conformity with the 26th apostolical canon, which permitted marriage only to those who held the office of readers or chanters in the churches.

The principal Papal decrees which have been issued by the popes on the subject of sacerdotal celibacy are the following. It is said that Calixtus I., who was elected in 221, renewed a constitution forbidding the marriage of priests. It is said, too, that Lucius I., elected in 255, re-

enacted the same prohibition. We do not, however, reach any certainty on the subject till we come to the Council of Elvira, the first of those on matters of discipline the decrees of which are extant. It is doubtful whether this council was held in the year 300 or 313. The thirty-third and thirty-sixth canons of this council command bishops, priests, deacons, and subdeacons to live apart from their wives. The council further prohibited ecclesiastics from having any female in their houses save a sister or a daughter, and those only when virgins, who had consecrated their virginity to God. The ecclesiastical writers maintain that these constitutions were but the confirmation by authoritative sanction of the practice which had been immemorably observed, rather as an apostolic tradition than a positive command. From that time to the time of Gregory VII. (the great Hildebrand, elected 1073), a series of popes issued decrees commanding bishops, priests, and deacons to observe celibacy. But all of them are couched in terms, and put forth under circumstances, which indicate that the regulation was by no means universally, perhaps even it may be said generally, observed. Gregory VII., in the council held at Rome in the year 1074, determined more decisively and vigorously that, according to the sacred canons and the decrees of his predecessors, no ecclesiastic could be a married man, that the sacrament of ordination should be conferred on none except those who professed perpetual celibacy, and that no wived priest should celebrate or even assist at the Mass.

Upon the whole it is clear that the pretension advanced by the Church of Rome to insist on the celibacy of its clergy was at first put forward tentatively and gradually, as a thing desirable and tending to higher perfection, rather than as a thing absolutely necessary; that, like so much else in that church, it was an encroachment on Christian liberty, originating in a mystic idea of the greater purity of a state of celibacy, which was a natural product of the working of the human intellect in the earliest centuries of Christianity, and became fixed and consolidated into a rigid law, as the rulers of the church, and especially Gregory VII., came to perceive that it was a potent engine of ecclesiastical power. It is probable that Hildebrand, the nature of whose intellect and temper was such as eminently to qualify him for perceiving, appreciating at its true value, and utilizing the doctrine of the universal celibacy of the clergy, was the first ruler of the church who clearly saw the incalculably enormous power which this rule placed in the hands of the hierarchy as a body, yet more notably than it tended to increase that of each individual priest. To this and to this alone it has been and is due that a Catholic priest is the citizen of no country, and acknowledges or at least feels no allegiance, unless perhaps a subordinate and secondary one, save to his church, and that to him his order is in the place of family and country; and the greatness, the power, the glory, and the supremacy of the church constitutes that for which the best minds among the priesthood labour and live. But while churchmen were becoming more and more alive to the vast importance of celibacy as a *sine qua non* of the priesthood, minds which were fitted to estimate that institution with a larger view to its ultimate results and consequences became at an early period aware of its veritable consequences. Erasmus, in his 19th Epistle (lib. 29) gives us at once his own and Augustine's views of the subject in the following remarkable passage:—"Mirum vero si proeus amans laudat nuptias, dicitque castum conjugium non multum abesse a laude virginitatis, quum Augustinus patriarcharum polygamiam anteponat nostro celibatui."

But when the church stood at the diverging of the ways, fabled in the apologue, and at the Council of Trent decided

once and for ever which of the two paths open before her she should follow, whether that of progressive reformation and amelioration, or that of a *sint-ut-sunt-aut-non-sint* persistence in her old ways and policies, the abolition of the celibacy of the clergy was discussed among other proposed measures of reform, and more peremptorily rejected than almost any other suggestion brought forward. The church understood too well what was around her, and too little what was ahead of her; was too clear-sighted, yet too shortsighted; and determined to retain the terrible engine of her power, which makes of her a caste, with a gulf between her ministers and the rest of humanity.

CELLINI, BENVENUTO (1500–1569), was born at Florence, where his family, originally landowners in the Val d'Ambra, had for three generations been settled. His father, Giovanni Cellini, was a musician, and artificer of musical instruments; he married Maria Lisabetta Granacci, and eighteen years elapsed before they had any progeny. The father designed Benvenuto for the same profession with himself, and endeavoured to thwart his inclination for design and metal work. When he had reached the age of fifteen, his youthful predilection had become too strong to be resisted, and his father reluctantly gave consent to his becoming apprenticed to a goldsmith, Antonio di Sandro, named Marcone. He had already attracted some notice in his native place, when, being implicated in a fray with some of his companions, he was banished for six months to Siena. After visiting Bologna and Pisa, and after twice resettling for a while in Florence, he decamped to Rome. On his next return to Florence, his violent temper again embroiled him in a quarrel, which again compelled him to retreat in disguise to Rome. Here he produced a vase for the bishop of Salamanca, which introduced him to the favourable notice of Pope Clement VII.,—likewise at a later date one of his celebrated works, the medallion of Leda and the Swan; he also reverted to music, practised flute-playing, and was appointed one of the Pope's court-musicians. In the attack upon Rome by the Constable de Bourbon, which occurred immediately after, in 1527, the bravery and address of Cellini proved of signal service to the pontiff; if we may believe his own accounts, his was the very hand which shot the Bourbon dead, and he afterwards wounded the Prince of Orange. His exploits paved the way for a reconciliation with the Florentine magistrates, and his return shortly after to his native place. Here he assiduously devoted himself to the execution of medals, the most famous of which (executed a short while later) are Hercules and the Nemean Lion, and Atlas supporting the Sphere. From Florence he went to the court of the duke of Mantua, and thence again to Florence and to Rome. Here he avenged a brother's death by slaying the slayer; and shortly afterwards he had to flee to Naples to shelter himself from the consequences of an affray with a notary, Ser Benedetto, whom he wounded. Through the influence of several of the cardinals he obtained a pardon; and on the elevation of Paul III. to the pontifical throne he was reinstated in his former position of favour, notwithstanding a fresh homicide of a goldsmith which he had committed in the interregnum. Once more the plots of Pier Luigi, a natural son of Paul III., led to his retreat from Rome to Florence and Venice, and once more he was restored with greater honour than before. On returning from a visit to the court of Francis I., being now aged thirty-seven, he was imprisoned on a charge (apparently false) of having embezzled during the war the gems of the pontifical tiara; he remained some while confined in the castle of Sant' Angelo, escaped, was recaptured, and was in daily expectation of death on the scaffold. At last, however, he was released at the intercession of Pier Luigi's wife, and of the cardinal of Ferrara, to whom he presented a splendid cup.

For a while after this he wrought at the court of Francis I. at Fontainebleau and in Paris; but the intrigues of the king's favourites, whom he would not stoop to conciliate and could not venture to silence by the sword, as he had silenced his enemies at Rome, led him, after about five years of laborious and sumptuous work, and of continually-recurring jealousies and violences, to retire in disgust to Florence, where he employed his time in works of art, and exasperated his temper in rivalries with the uneasy-natured sculptor Baccio Bandinelli. Here, as well as in a previous instance in Paris, he was accused of gross immorality; in his autobiography he rather repels than denies the charge, but he certainly repels it with demonstrative and grotesque vivacity. During the war with Siena, Cellini was appointed to strengthen the defences of his native city, and he continued to gain the admiration of his fellow-citizens by the magnificent works which he produced. He died in Florence on 13th December 1569, and was buried with great pomp in the church of the Annunziata. Besides the works in gold and silver which have been alluded to, Cellini executed several pieces of sculpture on a grander scale. The most distinguished of these is the bronze group of Perseus holding the head of Medusa, placed in front of the old Ducal Palace at Florence, a work full of the fire of genius and the grandeur of a terrible beauty, one of the most typical and unforgettable monuments of the Italian Renaissance. The casting of this great work gave Cellini the utmost trouble and anxiety; its completion was hailed with rapturous homage from all parts of Italy. Not less characteristic of its splendidly gifted and barbarically untameable author are the autobiographical memoirs which he composed, beginning them in Florence in 1558,—a production of the utmost energy, directness, and racy animation, setting forth one of the most singular careers in all the annals of fine art. His amours and hatreds, his passions and delights, his love of the sumptuous and the exquisite in art, his self-applause and self-assertion, running now and again into extravagances which it is impossible to credit, and difficult to set down as strictly conscious falsehoods, make this one of the most singular and fascinating books in existence. Here we read, not only of the strange and varied adventures of which we have presented a hasty sketch, but of the devout complacency with which Cellini could contemplate a satisfactorily achieved homicide; of the legion of devils which he and a conjurer evoked in the Colosseum, after one of his not innumerable mistresses had been spirited away from him by her mother; of the marvellous halo of light which he found surrounding his head at dawn and twilight after his Roman imprisonment, and his supernatural visions and angelic protection during that adversity; and of his being poisoned on two several occasions. The autobiography has been translated into English by Thomas Roscoe. Cellini also wrote treatises on the goldsmith's art, on sculpture, and on design. Among his works of art not already mentioned, and many of which have perished, are a colossal Mars for a fountain at Fontainebleau and the bronzes of the doorway, coins for the Papal and Florentine states, a marble Christ in the Escorial palace, a magnificent button for the pontifical cope of Clement VII., a Jupiter in silver of life size, and a bronze bust of Bindo Altoviti. (W. M. R.)

CELSIUS, ANDERS (1701–1744), a Swedish astronomer, was born at Upsala in 1701. After travelling in Germany, England, Italy, and France, he took part in the famous expedition which was undertaken in 1736 by Maupertuis, Clairaut, Camus, and others, for the purpose of measuring a degree of the meridian in Lapland. He became member of the academies of Stockholm and Berlin, and of the Royal Society of London, and was appointed secretary of the Royal Society of Upsala. He died in his native town.

in 1744, leaving several works on astronomical subjects, including *Observations on the Measurement of the Earth* (1738), *A new method of Measuring the Distance of the Sun from the Earth* (1730), and a paper in which he tried to show that the waters of the ocean are decreasing in volume.

CELSUS is the first writer against Christianity of whose objections we have any record. His history is involved in complete uncertainty. Our knowledge of his treatise is derived from Origen's work written against it. We should have expected some information from the Alexandrian in regard to the writer whose book he refutes. But when we examine Origen's statements carefully, we are led to the conclusion that Origen knew nothing about him. Celsus's treatise had been sent to him by Ambrosius with the request that he should grapple with its arguments. Origen had not heard before of the work or of the author. He thought that Christianity did not require a defence, but to please his friend, and with the hope of benefiting those who were not Christians, he set about the task assigned. In the performance of this task he could not help making conjectures in regard to the author. He speaks of him in the preface "as long ago dead" (c. iv.). "We have heard," he says in another passage (i. 8), "that there were two Epicurean Celsi, one in the time of Nero and this one [the author] in the time of Hadrian and afterwards." But he could not make up his mind definitely that the Celsus, the author of the treatise, was an Epicurean. He says that he is proved to be an Epicurean from other writings (i. 8). He again and again calls him an Epicurean (i. 10, 21; ii. 60). He allows that Celsus did not state in the treatise that he was an Epicurean (v. 3). He lays before his readers three suppositions in regard to him, either that he concealed his Epicurean opinions, or that he had changed to a better state of mind, or that he had merely the same name as the Epicurean (iv. 54). And he expresses his doubt quite distinctly,—"The Epicurean Celsus, if indeed he is the person that composed the other two books against the Christians" (iv. 36). The "other two books" here mentioned are in all probability, as Neander and Banr have shown, two parts of the book which Origen tries to refute, or that book and another which is mentioned as having been promised by Celsus. Origen expresses a similar doubt as to the authorship of a work ascribed to the Epicurean Celsus. "You see how in these expressions he as it were accepts the reality of magic. I do not know if he is the same as the person who wrote several books against magic" (i. 68).

From these passages the inference may be drawn that Origen was very much in the dark as to who Celsus was and when he lived. The indications in the work itself are not much more satisfactory. But there is at least a clear indication of a period before which it could not have been written. Celsus makes mention of Marcellina (v. 62), who, according to Irenæus (i. 20, 4), came to Rome in the time of Anicetus (154 or 155 to 166 A.D.). In the same passage he mentions Marcion and his followers, and whatever may be the date of Marcion's first arrival in Rome, we may again accept the statement of Irenæus (iii. 4, 3) that he flourished in the time of Anicetus. As the followers of Marcellina and Marcion are spoken of, we may infer that both Marcellina and Marcion had had considerable success in propagating their opinions at the time Celsus wrote. A third clue to the date might be found in the mention of Dionysius, an Egyptian musician with whom Celsus had associated (vi. 41). In all probability this Dionysius was the younger Dionysius of Halicarnassus who was termed *μουσικός*, and who dissembled in his books just such points as those to which Celsus alludes. If this were the case, Celsus must have lived in the time of

Hadrian, the period in which Suidas says that Dionysius flourished. But there is no conclusive evidence that this Dionysius lived in Egypt, though the epithet "of Halicarnassus" proves nothing to the contrary, as it merely denotes that he was descended from the rhetorician and historian Dionysius of Halicarnassus. Some have found an indication of a date in the circumstance that oftener than once Celsus speaks of "the king" (viii. 68, 73), while in one passage (viii. 71) he speaks of "those who now rule." They infer from this that there were two emperors associated together in the government, but that one of them was far more prominent than the other, in fact that they were Marcus Aurelius and his son Commodus (Keim, p. 265). But the inference is not warranted. The last expression is a general expression, not applicable to the emperors only but to all rulers of the period, and if the other statements were to be pressed they would rather point to a time when only one emperor was on the throne.

In this deficiency of evidence it is not wonderful that critics have varied widely as to the date of Celsus, but most have assigned a date somewhere between 150 and 180. Peter Faidit maintained that he flourished in the time of Nero, and in recent times Volkmar has argued for the opinion that Celsus was a contemporary of Origen (see *Supernatural Religion*, vol. ii. p. 228, ff.).

Outside of Origen's work we find no clue to the history of Celsus. The name was very common. Upwards of twenty persons of the name are mentioned within the first three centuries of the Christian era (see Keim for the list, p. 276). But there is only one for whom any one has claimed identity with the Celsus of Origen. This is the Celsus to whom Lucian sent his treatise *Pseudomantis*, giving an account of the imposture of Alexander of Abonoteichos. We think that this identification is a mistake. The Celsus of Origen is unquestionably not an Epicurean. The Celsus of Lucian could scarcely be anything else. The tractate of the satirist is full of extravagant praises of Epicurus. The defence of Epicurus as "a man truly holy and divine in his nature, and who alone with truth ascertained what was beautiful," is said to be specially agreeable to Celsus. The followers of Plato and Chrysippus and Pythagoras are alluded to contemptuously,—an allusion which would have applied pointedly to the Celsus of Origen. If an identity could have been proved, the date of Celsus would have been ascertained; for Lucian mentions the war of Marcus Aurelius with the Quadi and Marcomanni as a contemporaneous event. It is very likely that the Epicurean Celsus mentioned by Origen as living in the time of Hadrian is the same as the Celsus of Lucian.

Happily we are not left in the same doubt in regard to the treatise of Celsus as we are in regard to his life. In refuting it Origen adopted the plan of going through it in regular sequence, taking one passage after another in the order in which he found them in the book. He has not adhered to this rule with absolute fidelity, but his deviations from it are few, and as he generally quotes the exact words, a large portion of the treatise has thus come down to us. The remains of it are so numerous that we can form an accurate notion of the whole work. The treatise was called a "true discourse" (*λόγος ἀληθής*). Origen states at the end of his work against it (viii. 76) that Celsus intended to write a sequel to it, in which he was to supply rules of practical life for those who wished to embrace his opinions. Whether he ever carried out his intention history does not state.

In the *True Discourse*, Celsus shows great philosophical and critical powers. He takes note of almost every objection which has been brought against Christianity, and his position is substantially that which is assumed by the

scientific opponents of Christianity in the present day. The *True Discourse* is divided into two parts. In the first he does not speak in his own person, but introduces a Jew who discusses from the Jewish point of view the credibility of the statements made by Christians in reference to the life of Jesus. There was considerable advantage in this mode of procedure. Celsus himself did not believe in the supernatural. The only possibility of the existence of such a person as the Christian Jesus that he could conceive depended upon his being dæmonic, but Jesus showed nothing of that majesty, that grandeur, that energy of will in worldly affairs which he deemed essential to the dæmon. He therefore rejected his pretensions entirely as inconsistent with his philosophy; but he believed that even on the basis of a philosophy which permitted the supernatural the claims of Jesus must be rejected. And so his arguments are made to come from a Jew. The Jew rejects the miraculous birth of Jesus. Mary was divorced from her husband, and wandering about fell in with a Roman soldier, Panthera, who was the father of Jesus. Jesus being needy went down to Egypt and there learned all the tricks by which he could work apparent miracles, and on the strength of this knowledge he claimed to be God when he returned to Judea. But who could believe the statements made in regard to him,—who heard the voice at his baptism? None but himself and a companion who shared his dream or rather his imposture. The miracles ascribed to him are absurd. Any one could see such miracles by paying a few obols to an Egyptian juggler. If Jesus was God, would he have chosen such wicked and worthless men as his apostles? If he knew that Judas would betray him, why did he make him his companion? But the story of the resurrection especially seemed absurd. He was condemned publicly before the eyes of all. No one could doubt this. If he rose again, why did he not make his justification as public? Would he not have confronted his judge, his accusers, the general public, and given indubitable evidence that he was not a malefactor? And who saw him after he rose again? A half insane woman and one or two followers who were in the very humour to trust to dreams or to an excited fancy. In this way the Jew discusses many of the statements made in the gospels, and comes to the conclusion that Jesus was an ordinary man.

In the second part Celsus tests the beliefs of the Christians by his philosophical principles. He then shows that the Greeks had all that was true in Christianity, but in a nobler and better form, and he ends with a practical application, urging Christians to give up their separatist tendency, to worship the dæmons, and to join in all civil and military duties imposed on citizens by the state. Before dealing with the principles of the Christians he draws attention to the false position which they occupy. They are, he thinks, essentially rebellious. They wish to separate themselves from the rest of mankind. The Jews show this tendency, but they are so far to be excused in that they adhere to their national beliefs. These beliefs indeed are often silly and puerile, and perversions of what is wiser and better in Greek poets and philosophers. But the Christians belong to no nationality, and separate themselves from the ordinary beliefs without any good cause. They object to the divinity of the Dioscuri, Hercules, and others, in regard to whom the Greeks believe that they became gods from being men. And yet they worship a man who was a prisoner and died. This worship is on a level with that of Zamolxis by the Getæ, of Mopsus by the Cilicians, and of others whom he names. It is unreasonable. Accordingly the Christians do not invite the wise or the good. It is ignorant slaves, women, and children whom they try to influence, not publicly but in corners and private places. And their divisive tend-

encies are shown in the number of the sects which exist among them.

After this introduction Celsus proceeds with his philosophical argument. God is good and beautiful and blessed. He therefore cannot change. For if he were to change, it could only be for the worse. Therefore God cannot come down to men. He cannot assume a mortal body. He cannot do it in reality, for that would be contrary to his nature; he cannot do it in appearance, for that would be to deceive, and God cannot deceive. Indeed the idea is absurd. What advantage could be gained by his coming? Does he not know all things? Has he not power to do all things without assuming a body? Is he not able as God to do everything that he could do as incarnated God? And no real advantage is got for men; for they do not know God better by seeing him in bodily form. God must be seen by the soul, and men are deceived if they imagine they know Him better by seeing Him in a corruptible body than when they see Him with the pure eye of the soul. Indeed Christianity is in this respect marked by a gross anthropomorphism. Nor can the purpose which Christians assign for this incarnation be regarded as true. The nature of the whole is always one and the same. There is always the same amount of evil in the world. There is nothing evil in God. The evil is in matter. But God is continually making the evil serve for the good of the whole. If this is the case, then, it is absurd to suppose that God would be especially interested in a few of the human race. He works always for the whole. And the Christian notion is peculiarly absurd. Did God at that particular time waken from sleep and resolve to rescue a few from sin? Was He indifferent to all mankind before, to all the nations of the earth? And is He to continue to show the same special favour only for a select number? Not only are the Christians wrong in this, but they are wrong in supposing that the world was made for man. Again it is the whole that is cared for. And we can see signs in nature that animals are equal if not superior to man in many points. If he hunts the deer, the lion hunts him and feeds on him. Bees have cities and rulers. Some animals speak to each other. Some can foretell the future. Some are religious. In fact neither for animals nor man was the universe made, but that the world as God's work might be perfect in every part. In these arguments we have a remarkable anticipation of many of the points which come out in our present Darwinian discussions (see *Teleologie und Naturalismus in der altchristlichen Zeit: Der Kampf des Origenes gegen Celsus um die Stellung des Menschen in der Natur*, dargestellt von Dr. Phil. Aug. Kind: Jena, 1875).

In exhibiting the superiority of the Greek doctrines over the Christian, Celsus points to the circumstance that the Greeks appeal to reason, the Christians cry out, "Believe, believe." The doctrine of the Son of God, he thinks, was borrowed from Plato. The Devil owed his origin to a distortion of a Greek opinion. He compares the prophecies of the Greeks with those of the Christians, and he contrasts Greek and Christian doctrines of a future state, and speaks of the resurrection as a ridiculous belief.

In the practical application he maintains that the dæmons are subordinate ministers of God, and that therefore any worship paid to them is worship also of the Supreme God himself. Especially the Christians have no good reason for objecting to such worship since they already worship a dead man.

Our abstract of this work is necessarily very imperfect, and many important points we have been compelled to omit entirely. From what has been given, it will be seen that Celsus was a Platonist. He believed in a Supreme God, the Supreme Good, higher than all existence. This

God was everywhere and in everything. Alongside of this God was original uncreated matter, the source of all evil. These two made up the universe, which remained a constant quantity. There could, therefore, be no real redemption from sin. There could be nothing supernatural. There was merely the apparent evolution and involution of the same reason and matter. This mode of thought is fatal to final causes, fatal to a special aim on God's part, fatal to a special interest in man, and therefore fatal to Christianity.

The writers who have discussed Celsus and his opinions are numerous. Most of them are mentioned in the most recent work on the subject, *Celsus' Wahres Wort: älteste Streitschrift antiker Weltanschauung gegen das Christenthum vom Jahr 178 n. Chr.*, von Dr. Theodor Keim, Zürich, 1873. This is a translation of the *True Discourse*, with dissertations on the life, date, arguments, &c. of Celsus. The best expositions of the opinions of Celsus are given in Redepenning's *Origines* (Bonn, 1841); in Baur's *Die Christliche Kirche der Drei Ersten Jahrhunderte* (Tub., 1860); and in Kellner's *Hellenismus und Christenthum* (Cologne, 1866). The fragments of Celsus in Greek were collected by Jachmann (1836). (J. D.)

CELTIBERIA, the country of the Celtiberi, was an extensive inland division of Spain, lying between the basin of the Iberus or Ebro and the sources of the Tagus, Douro,

and Guadiana, and comprehending the greater portion of the modern provinces of Cuenca and Soria, the south-west half of Aragon, and part of Burgos. By the Romans the name was employed almost as synonymous with Hispania Citerior. It was a hilly and barren region, intersected with valleys of great fertility. Of the chief cities the most famous were Segobriga, the capital; Bilbilis, the birthplace of the poet Martial; and Numantia, besieged ten years by the Romans, and taken and destroyed by Scipio Africanus, 133 B.C. The Celtiberians, as their name imports, were considered to have arisen from the intermarriage of Iberians with the Celts that, having crossed the Pyrenees from Gaul, subdued and settled amongst them. The new race thus formed were a brave and powerful people, whose warlike qualities, improved by conflicts with their neighbours and the Carthaginians, rendered them formidable opponents of the Romans, whom they not unfrequently defeated. After their overthrow by Scipio, and their consequent alliance with their conquerors, they frequently revolted; but, on the assassination of their leader Sertorius in 72 B.C., they were subdued by Pompey, and from that time Celtiberia submitted quietly to Roman influence.

CELTIC LITERATURE

Ancient names of Celts.

THE Greeks gave the collective name *Keltai* to a Western people, and the name *Keltike* to the land which they inhabited. The region to which the latter term was applied varied according to the more or less accurate knowledge of each writer who used the term. The use of the word *Keltai* was equally vague and variable; and this was due as much to the great movements of peoples which took place some centuries before the Christian era as to the want of knowledge of the early Greek writers. One of the displacements of tribes due to those movements has immediate connection with our present subject, the migration of some of the *Keltai* by the valley of the Danube and Northern Greece into Asia Minor; for in the names *Galatai* given to the people, and *Galatia* given to the land wherein they settled, we have forms which connect the Greek *Keltai* and *Keltike* with the Roman *Galli* and *Gallie*, and both, perhaps, with *Góidil*, *Gaeidil*, or *Gaedhil*, the name of one branch of the descendants of the *Keltai*, or, to use the modern form of the word, Celts. If *Góidil*, or, in the modern Scottish form, *Gael*, be radically connected with *Keltai*, *Galatai*, and *Galli*, these names would represent that by which the original nation, or one of its principal tribes, called itself. We do not know the collective name by which the Germans designated their neighbours. Dieffenbach suggests that it may exist in *Ualidgastes*, a man's name, which, as frequently happened, from a tribe name became an appellative, and exists now in the modern German word *Held*.

Celtic ground.

When the Romans became first acquainted with the Celts there were two Gauls,—Cisalpine Gaul or Northern Italy, and Transalpine or Greater Gaul, which included not only France but also Belgium, all that part of Germany west of the Rhine, and Western Switzerland. Whether any Celtic tribes lived east of the Rhine since the attack of the Gauls on Rome, and whether the frontier of the Germans and Celts was a fixed one within historic times or a constantly advancing one, are questions which we have not space to discuss, nor, if we had, would it be profitable to do so in the absence of any real facts to work upon. To the Continental Celtic ground above defined we have to add the British Islands.

Celtic language.

The determination of the limits of the Celtic ground is based chiefly on linguistic evidence. Unfortunately, as regards the Continental part, our materials are scant, and

hence a good deal of room is left for the imagination. Thus it has been much discussed whether the language spoken in every part of ancient Gaul was the same. Some have asserted that the Belgians were Germans, and therefore spoke a Teutonic tongue, and that even the Celtic dialect spoken north of the Loire differed considerably from that spoken south of that river in Aquitaine. This opinion was based upon a well-known passage in *Cæsar's History of the Gallic War*, in which he states that Gaul was divided into three parts which differed among themselves in language, institutions, and laws. This may mean either that three distinct languages were spoken, or if but one language, that there were three well-marked dialects. M. Roget de Belloguet has shown from a careful investigation of all ancient authorities, and an analysis of nearly 400 Gaulish words gathered from ancient authors and inscriptions, that the differences in question were dialectic, and that, save, perhaps, in those parts occupied by a Ligurian or Basque people, the same language was spoken in all Gaul.

Community of language does not, however, necessarily imply community of race. People having no kinship may speak the same language, while others nearly akin may speak widely different languages. This has been found to have been the case in Gaul as elsewhere. One language was spoken by two races which gradually fused into one people—a northern, fair-haired, blue-eyed race, of tall stature, lymphatic temperament, and elongated heads, and a southern race, shorter in stature and dry and nervous in temperament, having brown or black hair and eyes and round heads. The free or dominant class of Gauls belonged to the former race, which was evidently an intrusive one. The inhabitants of the British Islands seem to have been composed of the same two races, and to have spoken the same language as those of Gaul.

Causes of phonetic change like those which produced the parallel branches of the Teutonic stem (the Germanic and Scandinavian tongues) and of the Windic stem (the Slavonic and Lithuanian tongues) must have existed at an early period in the Celtic language, for the original stem has produced two branches in the British Islands which are wider apart than those of the Teutonic stem, and, according to Zouss, less widely separated than the two branches of the Windic stem. These branches we shall call, following

Branches of Celtic language.

Zeuss, the Irish and British branches. Each of these branches has again produced three dialects. The Irish or Goidelic dialects are—the Irish proper, the Scottish Gaelic, and the Manx, or dialect of the Irish spoken in the Isle of Man. The British dialects are—the Kymraeg or Welsh, the Cornish, and the Armoric, or language of Brittany. The Cornish is now extinct, having died out about the middle of the last century. We have included Armoric among British dialects on the ground that whatever may be its relation to old Gaulish it was intimately connected during the Middle Ages with the Cornish, if it be not a direct descendant of the language spoken by the southern Britons who emigrated to Brittany during the early Saxon wars.

Distinction
between
branches
of Celtic
language.

It would be impossible within the limits of such an article as this to point out even the principal distinctions between the two branches of the Celtic, but the following examples will perhaps enable the reader to realize their general character. The Irish has preserved the hard or *k* sound of *c*, while in British it is represented by *p*;—e.g., Irish *cethir*, four, *cland*, posterity, *crann* tree, with initial guttural, are equal to the Welsh *petguar*, plant, *pren*; Irish *nach*, *nech*, person, *macc*, son, with final guttural, and *cach*, each, with initial and final *c*, correspond respectively with Welsh *nep*, *map*, and *paup*. This change from a guttural to a labial, and even in some cases to a dental, is what Professor Curtius calls “labialismus,” and is very marked in Greek as compared with Latin; so that as respects this phonetic law Welsh stands to Irish in the same relation as Greek does to Latin. The tendency to labialism is, however, less in Irish than in Latin, e.g., Latin *septem*, seven, Irish *secht*; and perhaps even than in Sanskrit, for Irish drops initial *p*, e.g., *iasg*, fish, Welsh *pysg*, or changes it into *b*, e.g., Welsh *pen*, Irish *ben*. The reverse process to labialism even sometimes takes place in the case of borrowed words, e.g., *Pascha*, Easter, Welsh *Pasg*, Irish *Casg*; Latin *purpura*, Irish *corcur*. So great is the contrast in this respect between Irish and Welsh, that the latter labializes borrowed names, as in the case of the Irish Saint *Cia.an*, who became *Piaran* in Wales. If Dr Windisch, Mr J. Rhys, and some other philologists are right in thinking that the primitive or true *p* sound when not combined with other consonants has disappeared everywhere from all the Celtic languages, and that when *p* does appear in them, especially in Welsh, it is only the representative of a former *qu*, *mb*, or of a protracted *b*, that is a *b* carried forward from the end of one word to the beginning of the next, then the distinction just dwelt upon, though very marked when we compare modern Welsh and Irish, did not exist in ancient times. But whether this be so or not the Irish articulation maintains a good deal of hardness and strength, in illustration of which we may mention that *cn* and *sr* occur as initial sounds—the latter, which is also found in Sanskrit, does not exist perhaps in any other European language. Again, Irish, like Sanskrit, Latin, German, and Slavonian has preserved the sibilant *s*, while in British, as in Zend, Persian, and Greek, it has been generally changed into *h*, e.g., Irish *sen*, old, Welsh *hen*, Irish *salann*, salt, Welsh *halen*; or the *s* when combined with other consonants has a prefixed *y*, as in Irish *scarad*, separation, Welsh *yscar*. As regards this change of *s* into *h* British also stands to Irish in the same position as Greek does to Latin, e.g., Latin *sal*, Greek *ἅλς*. Like the labialism above pointed out, this change did not, however, constitute an ancient distinction. Irish words can also end in *s* and *r*, and in *n* probably derived from *m*. Of these, final *s* disappears first, but we have an example of the preservation of a final *r* in so common a word as *athir*, father, when it has lost the initial labial. British has often *v* or *w* for an *m* in Irish, e.g., *louan*, a rope,

Irish *loman*; *huvel*, low, Irish *humal*. All the dialects of the British do not do this equally; thus Irish *amail*, *amal*, like, is *auel* in Cornish, and *euel* in Armoric, but *mal* in Welsh. And again the Irish preserves letters where the British loses them; this is especially the case with gutturals, e.g., Irish *tecl*, house, Welsh *ti*; Irish *nocht*, night, Welsh *nos*; Irish *teglech*, household, Welsh *teulu*. And, lastly, Irish has preserved the declension of its noun even to this day; and forms closely allied to old Indo-European declensions are found in Old Irish, but with the exception of the genitive in Cornish scarcely a trace of declension is to be found in British. Irish verbal forms are also much better preserved than the British ones, though the latter are in a better state than the nouns.

As regards the dialects of each branch, the Irish ones differ less from each other than do the British dialects. Irish proper and Scottish Gaelic are practically the same language, and do not differ greatly more than the dialect of English spoken in the Scotch Lowlands does from common English. Such differences as do exist indicate the modern origin of the Scottish Gaelic. Among those differences the following will bear out this opinion. In the genitive plural the initial consonant is not modified, or, as Irish grammarians say, does not suffer ellipsis in Gaelic as it does in Irish. Thus a Highlander says *nan cos*, of the feet, where an Irishman would say *na g-cos*; the former would, however, use *nam* before a labial, as e.g., *nam fear*, of the men. Again the possessive pronouns *ar*, our, *bhur*, your, do not cause ellipsis in Gaelic as in Irish, e.g., *ar buachaill*, our boy, Irish *ar m-buachaill*; *bhur cosa*, of your feet, Irish *bhar g-cosa*. Again there is the frequent ending of the nominative plural in Gaelic in *an*, as in *slatan*, rods, a peculiarity which it shares with Manx and Welsh, and probably derives from British; writing the personal ending *-aire*, or *-oir* as *-air* in Gaelic, e.g., *sealgair*, a huntsman, for *sealgaire*, and the personal ending *-aidh* as *-aiche* or *-iche*, e.g., *coisiche* for *coisidhe*, a footman; writing the Irish termination *-ugadh* in progressive active nouns as *-uchadh*, e.g., *gradhachadh* for *gradhughadh*; writing the passive participle always hard instead of softening it under certain circumstances, as in Irish, e.g., *ta, tha; te, the*. Among the less marked differences we may point out the use of the negative *cha* in Gaelic for the modern Irish *ni* and old *nocha*, the more frequent use of the auxiliary verb *tá* in conjugation, and the absence of *f* in the future indicative and in subjunctive in Gaelic. Manx differs from Irish much more than Gaelic; but the dissimilarity is not nearly so great as at first sight it appears to be, owing to a kind of phonetic spelling having been adopted in Manx through which the radical letters have often been lost. Manx has been much corrupted, too, in consequence of the connection between Ireland and the Isle of Man having been cut off by the Norse conquest, and also by its having been under the dominion of Wales for some time; add to which that it never received literary cultivation. The chief differences are in orthography,—the ending of the nominative plural in *n* already alluded to, the dropping of a final vowel, the substitution of *d* for *g*, and of *t* or *c* for *g* in the middle or end of words, &c.

Of the British dialects Cornish and Armoric resemble each other more than either of them does Welsh. This resemblance is, however, not as great as that of the Irish and Scottish Gaelic, but perhaps as close as that between Spanish and Portuguese, especially if the later borrowings from English and French be excluded. As to the words borrowed by the Cornish from French, which are much more numerous than those taken from English, it is interesting in connection with the history of romance to note that many are borrowed directly from Provençal. The difference between Welsh and Cornish and Armoric is con-

siderable; Mr Edwin Norris thought it to be as great as that between French and Spanish. Besides the difference in their vocabularies, which is, of course, largely due to the great number of words borrowed by the southern British dialects, especially by Cornish, we may mention the following points in which Cornish differs from Welsh, and these will serve to indicate the general character of the difference between the latter and the southern dialects as a whole:—the retention in Cornish of an initial *s* combined with other consonants without prefixing *y*, e.g., *scol*, *scod*, *spyrvt*, which in Welsh are weakened to *ysgol*, *ysgwydd*, and *ysprydd*; the diphthongation of vowels in Welsh in cases where Cornish preserves the strong vowel, e.g., Cornish *tron*, *tom*, *scouth*, which are in Welsh *trwyn*, *twym*, and *ysgwyd*; the better preservation of consonants in the middle of words in Cornish than in Welsh, e.g., Cornish *hanter*, *stereu*, *vallvat*, *canteuil*, which have been reduced in Welsh to *hanner*, *seren*, *gwallowiad*, *canyll*; and lastly the preservation in Cornish of a genitive case in complete conformity with the Irish.

The question naturally suggests itself here, when did the original Celtic stem divide into the two branches described? and again, when did each of those branches produce their dialects? The late Mr Edwin Norris was of opinion that the separation took place after the arrival of the primitive stock in the British Islands. This opinion appears to be in entire conformity with all the facts of the case, ethnological, linguistic, and historical. We have already indicated that the Scottish Gaelic is an essentially modern dialect, which has an existence of only a few centuries. It is probable that pure Irish was spoken in the Isle of Man in the 6th and 7th centuries, that is, Irish exhibiting no greater dialectic variety than existed at the same period between any two provinces of Ireland itself, so that the Manx dialect must have grown up since then. Of the two branches the Irish is the most archaic, that is it has preserved more of the characteristics of the original stem. Among the British dialects the most archaic, that is, the one which best represents the British branch, is Cornish, which is the descendant of the speech of the un-Romanized Britons of England. This was also the opinion of Mr Norris, who held that the older the Welsh the more closely would it approximate to Cornish. It is indeed probable that the Welsh dialect originated in the 5th and 6th centuries, when the conquests of the Saxons began to isolate Wales from the other British-speaking people. The separation of Cornish and Armoric is still more recent, a fact which supports the story of the emigration of Britons to Armorica, and of long-continued intercourse during the early Middle Ages.

If the preceding view of the origin of the two branches of Celtic and their respective dialects be correct, it disposes once for all of a very vexed question, namely, did old Gaulish belong to the Irish or to the British type, or, to put it more correctly, to which of those types would the dialects belong which would have grown up in France if Gaulish had not been suppressed by Latin? The usual view has been that the Gaulish belonged to the same type as the British. Grimm's attempt to prove that the medical incantations contained in the book of Marcellus of Bordeaux, a physician of the 4th century, were Celtic of the Irish type led to a modification of this view. Amédée Thierry assumed that the Gauls proper spoke a dialect of the Irish type, while the Belgæ and the Gauls or Galatians of Asia Minor spoke Cymric or British. Such a view implies that Irish and British had already grown out of the original stem before the advent of the Celtic people in the British Islands and Gaul; and further that two distinct waves of Celts had come into Western Europe, the first or oldest being the Goidelic or Irish, and the

second the Cymric or British. Edward Lhuyd, the father of Celtic philology, long ago suggested an hypothesis of this kind as an explanation of the occurrence of geographical names in Britain which appeared to him to be Goidelic rather than Cymric. Zeuss threw the weight of his great authority into the scale in favour of the kinship of the old Gaulish and Cymric. The grounds on which he based his opinion have since, however, been altogether explained away, or their force much weakened, especially since the investigations of Gluck and Roget de Belloguet on the Gaulish vocabulary which has been collected from classic authors and inscriptions, and the increased knowledge of the Celtic dialects, the study of which Zeuss himself so powerfully promoted.

Mediæval Irish and Welsh manuscripts contain an extensive body of legendary ethnology, which in the case of the Irish legends has been even fitted with a complete chronology. Setting aside the more fabulous parts of the Irish legends which refer to colonists who arrived a short time before and after the deluge, we find four successive colonies mentioned in the following order:—*Nemedians*, *Firbolgs*, *Truatha Dé Danann*, and *Milesians*. The *Nemedians* are said to have occupied the country during only two hundred years, when the greater part of them went away in three separate bodies, owing to the harassing attacks made upon them, and their final overthrow, by a people who appear in Irish legends as sea-rovers, called *Fomorians*. One body took refuge in Britain, another went to Thrace, and the third into the north of Europe. The Thracian party became the ancestors of the second colonizing race, the *Firbolgs*. The *Nemedians* who went to the north of Europe appear afterwards as the *Truatha Dé Danann*; those who went into Britain became the Britons. According to this legend three of the early tribes which peopled Ireland were of the same race with the Britons. The fourth and latest of the Irish races, the *Milesians*, or followers of *Miled*, are also connected with the others in the genealogies to be found in Irish manuscripts, but the relationship is much more distant than that which is represented to have existed between the other races. All Irish accounts of the early races inhabiting Ireland agree in bringing *Miled* from the north of Spain; but in the early times when the Irish ethnic stories received their present shape, the majority of people, not alone in Ireland, but everywhere, had very imperfect notions of geography, and often applied the few geographical names which had reached their ears by pure hazard, and generally without having more than the vaguest notions of the places they referred to. A perusal of Irish and, we may add, of Welsh poems and tales will bear out what is here stated. Spain in the Milesian story probably means no more than that the Milesians, whoever they were, came from a distance, and not from neighbouring countries with which the early Irish had intercourse. Ethnic traditions as a rule do not add much to our knowledge, but it is always dangerous to ignore them altogether because they must necessarily contain some truth. Of all the Irish traditions of this class those only seem to possess real importance which relate to the mysterious people called the *Truatha Dé Danann*. This name appears to mean the tribes of *Dé* and *Ana*; and as *Dé* is God, and *Ana* is called the mother of the Irish gods, these supposed invading tribes are only the deities in a system of mythology which has yet to be unravelled.

All these deities descend from a common ancestor, the Irish *Alldai*, or All-God, and appear to form two lines—the *Aes* *mythology*, *Trebair* and the *Aes* *Side*, probably analogous to the Teutonic *Vanir* and *Æsir*. The close resemblance between the Irish and Norse words *Aes* and *Æsir* can hardly be accidental. The former signifies a people; the latter is connected with the Norse *ans* and the Anglo-Saxon *as*, God, which occurs in many men's names. The *Sid* was

Irish ethnic traditions.

Age of existing branches and dialects.

Gaulish language.

the heavenly fort of the *Aes Síde*, as *Asgard* was of the *Æsir*. The *Mná Sidhe*, women of the *Sídh*, or in the singular *Bean Sídh* (pronounced *Banshee*) of modern fairy mythology, represent the goddesses of the *Aes Síde*. As in other mythologies, the same deity was endowed with different attributes and received different appellatives. The mediæval genealogists who looked upon the *Tuatha Dé Danann* as a real human race, thought it necessary to provide a place in the genealogies which they invented for every different name, and so added confusion to what was before obscure enough.

As some of those deities occupy a place in Celtic romance, we shall venture to say a few words about some of them, though at the risk of making one out of several distinct deities, and of making several out of one. In a subject of inquiry which has been hitherto almost entirely uncultivated, and all but unknown, this is nearly inevitable; but a few mistakes, should we make them, will not seriously interfere with the object we have in view. One of the chief deities of the Irish pantheon was *Ogma*, surnamed *Griainneach*, "of the sun-like face," son of *Eladan*, or *Elathan*, that is, of knowledge. *Ogma* had other appellatives, the most important being *Dagda*, *Delbaith Dana* or *Tuircenn Bircenn*, and *Cermait* "of the honey-mouth," though the last sometimes appears as the son of the *Dagda*. Under the last appellation his wife is *Ana*, the mother of the gods, or the *Mór Rígu*, or *Mór Rígan* also known by the appellatives of *Badb* and *Macha*. As the latter, she was the mother of *Aed* (fire), who is probably the *Aed Mawr* of Welsh legends, father of *Prydain*, the first legendary king of Britain, whence the name *Ynys Prydain*, or the Island of *Prydain*, and the real origin of the mythical *Iu* of the mediæval bards. The *Dagda* had another son, whose name was *Aengus*, or the *Mac Og*, a celebrated personage of early Irish legend, and an equally celebrated daughter, *Brigit*, the goddess of wisdom and judgment. Under the appellation of *Delbaith Dana* or *Tuircenn Bircenn* (who is represented as the son of *Ogma*, and not that personage himself), *Ogma* has two wives, *Ana*, under that name, and of her other two appellatives, and *Ernmas*, who is represented as the mother of the first-named wife; *Ana*, under her various names, is therefore at once the daughter and wife of *Delbaith*. *Ana's* sons by *Delbaith* are *Brian*, *Iuchair*, and *Iucharba*, who are called the gods of *Ana*, and hence she is called the mother of the gods. They are the same as the sons of *Cermait* "of the honey-mouth," already mentioned as being an appellation of *Ogma* himself, or his son under that of the *Dagda*. These sons are *Scithoir* or *Mac Cuill*, a sea-god, *Teithoir* or *Mac Cocht*, the ruler of the sky and heavenly bodies, to whom the plough was sacred, and *Ceithoir* or *Mac Greine* (son of the earth), the god of the earth. Their mother was the *Etain* of Irish legend; and as she was the wife of *Ogma* under that name, it proves that *Cermait* "of the honey-mouth" was only an appellation for the latter, and not his son, under his appellation the *Dagda*. The wives of the three gods above mentioned were *Banba*, *Folla*, and *Eire*, names under which Ireland was personified. *Elcmair* was either a son of *Ogma* as *Delbaith*, or more probably his brother, and was the same as *Tadc Mor*, *Orbsen*, and *Lér* (the sea). Under the last-named appellation he was god of the sea, and is especially interesting, for in him we have the original of Shakespeare's King Lear, and the father of *Manandan* of Irish and Welsh romance. It is probable that *Lér* was the same as *Mac Cuill*, the sea-god above mentioned. There was also a god of war, *Neit* (battle), whose son *Esery* (slaughter) was the father of *Diancécht Dia na-cécht*, the god of the powers (of healing), of *Goibniu*, the smith, and of other impersonations of the Arts. The god of healing had a son *Cian* or *Conn* (valour), who is also known under other appellatives, such as *Scalbalb*, and is sometimes confounded with his wife *Ethlenn* or *Ethne* (skill). His daughters were *Airmed*, the goddess of physic, and *Etain*, the wife of *Ogma*, above mentioned. *Ethlenn's* son *Lug* is a prominent figure in Celtic romance, and was known also by the names of *Lug Lámfada*, or *Lug* "the long-armed," *En*, and the *Sab Idanach*, or pillar of many arts. *Abhean*, the grandson of *Ethlenn* and *Conn*, was god of music. *Conn*, under his appellation of *Scalbalb*, is also made one of the sons of *Echaid Garb*, son of *Breas* (power), personages who fill prominent parts in Irish story. Among the other sons of *Echaid* we must mention *Badb Derg*, the chief of the *Síde* of Munster, and *Uillind Faebair Derg*, who kills *Manandan Mac Lir* in a legend. The deities related to *Conn* or *Cian*, husband of *Ethlenn*, and his son *Lug* are called the *Aes Trebair*, while those related to the *Dagda* or *Ogma* are the *Aes Síde* of story. The two tribes appear in contention or warfare, but, nevertheless, occasionally associated and intermarry, like the Teutonic *Vanir* and *Æsir*; thus *Etain*, the daughter of the god of healing, was the wife of the *Dagda*, and *Cermait* "of the honey-mouth;" and *Fea* and *Nemand*, the goddess of war, the wives of *Neit* or *Neid*, the god of war, were the daughters of *Elcmair* (great evil), known also as *Lér*.

Before leaving the subject of the early races of Ireland we shall say a few words upon a people incidentally mentioned above, the Fomorians. In Irish legends they appear as sea-rovers who only occasionally visited the coasts, pillaged and oppressed the people by levying tribute, or rather holding the inhabitants to ransom. One of the principal battles of Irish legendary history is supposed to have been fought between the *Tuatha Dé Danann* and the Fomorians. Even did we not know, as in this instance we do, that one of the contending races was mythical, we should naturally be inclined to regard such ethnic quarrels as imaginary, unless where we had unquestionable physical evidence of the occurrence of the struggle. On the other hand, in the case of mythologies which reach us, not as the recorded living belief of a people, but as the traditions of a prehistoric time, clothing real personages, who lived just at the close of that period, in what we might call the twilight of the historic period, and around whom as lay figures gather and assume definite shape fragments of old beliefs, we should always expect to find some nucleus of fact in legends relating to such ethnic wars. That the Fomorian and *Tuatha Dé Danann* contests are mythological there can be no doubt, but the kernel of fact around which the myths have gathered is the contests of the Irish and the Romans; in other words we believe the Fomorians to have been the Romans. The latter never made any settlements in Ireland, but there can be no doubt that they kept a few galleys in the western ports of Britain to protect the country from the hostile incursions of the Irish or Scots, and that they often chased these into Irish ports, and forced them to pay ransom. The accounts of the Fomorians in Irish story are just in accordance with this view, which can be supported by other evidence, into which, however, we cannot enter here.

The Welsh or Cymric ethnic traditions are not so elaborate as the Irish, nor do they in their present form bear the same appearance of antiquity about them. According to the Triads, a peculiar kind of literature to which we shall return hereafter, four classes of tribes entered Britain—the social, the refuge-seeking, the invading, and the treacherous tribes. The social tribes, of which there must have been three to make a triad, were the *Cymry*, the *Lloegrwys*, and the *Brython*, who were all of the same race and closely related. The *Cymry* like the Irish Firbolgs came from the summer land called *Defrobani* or Greece, or to speak as precisely as the Triads, from "where is now Constantinople, by way of the Hazy Sea," or German Ocean. The *Lloegrwys*, or Loegrians, came from the land of *Gwasgwyn*, not Gascony, however, but the country of the Veneti, about the mouth of the Loire, between whom and the Britons there appears to have been much intercourse in the time of Cæsar. The *Brython* or Britons came from *Llydaw*, that is Armorica, or rather that part of France which lies between the Seine and the English Channel, and which, therefore, included Normandy as well as Brittany. The refuge-seeking tribes were the *Celyddon* in *y Gogledd*, the *Gwyddel* in *Alba*, and the men of *Galedin*. *Y Gogledd* was apparently a general term among early Welsh writers for all the country between the Ribble and the Clyde inhabited by Britons; but it probably had a more restricted meaning, of which we shall speak presently. The *Celyddon* can hardly be other, at least in name, than the Caledonians, and were probably a Pictish tribe which had settled in the great forest district amidst the British people of the Scotch Lowlands. The *Gwyddel* of *Alba* were the Picts, and as the name *Gwyddel* implies, they were Gaelic. *Gwyddel* is the Welsh form of the old Irish *Góidil*, or in its modified later form *Gaeidhil*, or phonetically *Gael*. The men of *Galedin*, the present Galloway (Wigtown and Kirkcudbright), were part of the tribes

known in Ireland as *Cruitne*, that is Picts, and only differed from the *Gwyddel* or Picts of *Alba*, in having come into Galloway from Ireland. The three invading tribes were the *Coraniaid*, the *Gwyddel Ffichti*, and the *Saeson* or Saxons. The *Coraniaid* are said to have come from "the land of *Pwyl*, and they could not be driven out," but dwelt about the River Humber and the shore of the North Sea. If these be the same as the people known to the Romans as the *Coritani*, they were probably Picts of the same tribe as the Irish Picts, for there can be no doubt that *Cruitne* and *Coritani* are the same word. The *Gwyddel Ffichti* or Irish Picts who came to *Alba* by the Sea of *Llychlyn* (Norway), that is the North Sea, were doubtless a branch of the same Picts who settled about the Humber, in Galloway, and in Ireland. The three treacherous tribes were the *Gwyddel Coch* or Red *Góidil*, or *Gael* from Ireland, the men of *Llychlyn* or Norsemen, and the *Saeson* or Saxons. The Triads expressly tell us that the *Cymry*, the *Lloegrwys*, and the *Brython* were of the same stock. The different tribes of the *Gwyddel* or *Gael*, including the *Coraniaid*, were simply part of the same people who inhabited Ireland. We therefore assume with Mr W. F. Skene that the Picts and *Gael* were the same people.

Ethnic character of British people.

It thus appears that all the Celtic inhabitants of the British Islands consisted of two branches, which though originally the same people had branched off from each other in language and in other ways, producing the two classes of Celtic dialects, the Goidelic or Irish and the British, as we have above pointed out. But while we agree with M. de Belloguet that the Gauls were one in race and language, and, moreover, believe that the people who inhabited the British Islands were the same as those of Gaul, and that the divergence which we now observe between the Goidelic and British dialects first took place after their arrival, there seems no reason to doubt that the Celtic population flowed into these islands in two streams, one from the neighbouring Gaul, and one from some country east of Gaul by way of the North Sea,—the *Coretani*, the *Gwyddel Ffichti* from about the Forth, the Irish *Cruitne*, and the Scots forming part of the latter stream, and, if our conjecture be correct, the latest comers, a view in harmony with ethnic traditions, but differing from the ordinary opinion that the so-called *Cymry* came long after the *Góidil*, and drove them westward, they themselves being in turn pushed in the same direction by the incoming Saxons.

It would be interesting to pursue the subject of the ethnology of the early races of the British Islands through the conflicts and displacements of races which took place between the landing of Caesar and the final retirement of the Romans in the 5th century. But as this is not absolutely necessary for the illustration of a literature which only dates from the latter event, we shall content ourselves with giving a sketch of the ethnic distribution of the people of Britain resulting from the conflicts and displacements referred to as it existed in the beginning of the 6th century, when we are on sure ground in the history and literature of Ireland at least. Without such a preliminary sketch much that we shall have to say of great importance in the history of Celtic literature would be unintelligible.

Ethnic distribution of British population.

In the end of the 5th and beginning of the 6th centuries external invasions had ceased, and the different races had gathered into separate states, and commenced a struggle for mastery. In England the Saxons (using that term as a collective name for Saxons proper, Frisians, Angles, and Jutes) held possession of the southern and eastern coast from Dorsetshire to the Humber—the Angles chiefly occupying what is now Suffolk, Norfolk, and Lincoln—and were gradually making themselves masters of Central England towards the Severn, and were even penetrating northwards

between the vale of the Ouse and the Pennine Chain, into what is now the West Riding of Yorkshire. With the exception, perhaps, of the immediate neighbourhood of the south-eastern coast, where the continuous arrival of fresh bands of Saxons had driven away the British inhabitants, and of the district about the Humber where in like manner the fresh bands of Angles continually coming must have done the same, we are not to assume, as is usually done, that the former British inhabitants, called by the Welsh *Lloegrwys* or Loegrians, had all been exterminated, or driven away. On the contrary as the Saxons advanced inwards and the external invasion practically ceased, an increasing proportion of Britons must have been left. The new comers merely dispossessed the British ruling families, as the Norsemen did in Normandy, and as happened afterwards in Ireland, and left the bulk of the peasants. This was unquestionably the case in Central and Western England, and in Deira and Bernicia, the present counties of York, Northumberland, Durham, and the eastern Lowlands of Scotland. Cornwall and Devon were independent British kingdoms. What the Saxons had done on the southern and eastern coast the Irish did on the west. We cannot enter here into the question of when the Irish occupation of Western England commenced, or how long it lasted; there is no doubt, however, now that in the 5th century they occupied a considerable part of Gwynned, or that part of North Wales now forming Anglesea, Carnarvon, Merioneth, Denbigh, and Flintshire; and Demetia, or that part of South Wales now forming Cardigan, Pembroke, and Carmarthen, or in other words, the north and west coast of Wales. But while the Saxons were gradually displacing the British rule in the east, the Britons were gradually dispossessing the Irish in the west. The leaders of these Britons were the descendants of a certain *Cunedda*, reputed to have been a *Gwyddel* or Pict of the east of Scotland. Another *Gwyddel*, but probably one from Ireland, who like *Cunedda* was said to have married a British wife, *Brychan*, has given his name to Brecon or Brecknockshire. *Brychan* may, however, have been only the eponymous ancestor of the Goidelic families of Brecon.

The west of Britain from the Dee to the Clyde, with the exception of Galloway, was occupied by independent British tribes, apparently confederated for purposes of war. On the eastern side between the Humber and the Tyne was *Dyfer* or Deira, also British at this period; and north of Deira, was *Bryneich* or Bernicia, which extended to the Forth. These two states probably formed in the beginning of the 6th century part of a confederation of Cumbrian states. But in the course of that century they seem to have been gradually converted into Anglian states without any serious displacement of population, or even of ruling families. On the shore of the Firth of Forth was a district called in Welsh *Guotodin*, the eastern part of which about the Pentland Hills was called *Manau Guotodin*, and was occupied by a tribe of Goidelic or Irish Picts, who, there is reason to believe, had also settlements in other parts of *Bryneich* along the east coast. It was from this tribe that *Cunedda*, if, as is probable, he was not an eponymous ancestor, had sprung. The remainder of *Guotodin*, between the Lammermoor Hills and the sea, seems to have been also at least partially occupied by another foreign people, most probably Frisians. On the western side, in what is now Argyllshire, north of the Clyde, a settlement of Scots, who had gradually leaked in there from the opposite coast of Ireland, had been formed, and had become organized into a distinct state which was ultimately destined to absorb the whole of Scotland, and give it its present name. The remainder of the country north of the Forth and Clyde was occupied by the Picts,

properly so called, a Goidelic people closely akin to, indeed almost identical with, the Irish. In Galloway was another branch of Picts, called *Gwyddel Efrichti* by the Welsh, that is, Goidelic or Irish Picts, part of the *Cruithne* who leaked over from Ireland like the Scots.

In the beginning of the 6th century the Romanized Britons were giving way everywhere before the Teutonic tribes, and the only independent territory which they appear to have held comprised—(1) The Damnonian kingdom of Devon and Cornwall; (2) the part of Eastern Wales now forming Montgomeryshire and Radnorshire, which later formed the principality or lordship of *Powys*, and perhaps even yet all the land to the Severn, that is, Herefordshire and Shropshire; (3) Cumbria, that is, all the land from the Ribble to the Solway west of the Pennine chain, and all the Lowlands of Scotland to the Roman Wall, save Galloway, and *Guotodin*, or Linlithgow (including part of Stirlingshire), Edinburgh, and Haddingtonshire; (4) *Bryneich*, Bernicia, that is, Berwickshire, Durham, and Northumberland; (5) *Dyfr*, or Deira, that is, Yorkshire. The ancient dioceses of Scotland, even as they existed in the 13th century, seem to mark out very well the ethnic condition of the Lowlands in the early part of the 6th century. The diocese of Galloway included the territory of the Irish Picts; the diocese of Lothian, which had three rural deaneries—(1) Linlithgow, or *Manau Guotodin* (comprising the shire of that name, part of Stirlingshire, and the most of Edinburgh), occupied by the *Brithwyrr*, a mixed race of Picts and Britons, according to Mr Skene; (2) Haddington and the remainder of Edinburgh, that is, *Guotodin*, in which, as we have said, there was an early settlement of Frisians, or Angles; and (3) Merse, that is, Berwick. The continued existence of a Goidelic or Pictish population on the south side of the Firth of Forth, even in Berwickshire, down to as late as the 8th century at least, seems to be shown by the existence there of churches belonging to the ancient diocese of Dunkeld. In the 13th century they formed a separate deanery of that diocese, which appears to have corresponded with the Goidelic population of *Guotodin*. *Prydain*, the Cymric or true British country of the Lowlands, was consequently conterminous with the diocese of Glasgow, comprising the five rural deaneries of Glasgow proper—Rutherglen, Lennox, Lanark, Kyle and Cunninghame, and Carrick; and the four deaneries of the archdeaconry of Teviotsdale,—Teviotdale, Peebles, Nithsdale, and Annandale. This was the region called *y Gogledd*, though it is probable that this term was applied to the whole of the independent British territory, that is, Cumbria as well as *Prydain* proper; but whatever was its extent, *y Gogledd* was the cradle of the language and literature of Wales. It was the country of its prehistoric poets Aneurin and Llywarch Hên, and of the seer Merlin, whose fame was so great in the Middle Ages, and who is also reckoned among the early poets of the Welsh.

To complete this ethnic picture of Britain at the dawn of Celtic literature it would be necessary to give a sketch of the political and social state of the various Celtic tribes, so far as we could directly or by induction ascertain it. But as the articles BREHON LAW and CLANS give perhaps enough of this kind of information for the purpose we have in view, we refer the readers to those articles.

The Druids. In the earlier stages of tribal organization among the Aryans and other races, the chief was priest as well as king. But the Celts appear to have already passed into a higher political stage before they came within the light of history, and to have established a distinct priesthood known to us as that of the Druids. Greek and Roman writers give us very little information on this subject, and the early Welsh records and poetry none at all. Modern

Welsh writers have, however, made up for this want in their genuine literature by inventing an elaborate Druidical system of religion and philosophy, which, they pretend, survived the introduction of Christianity, and was secretly upheld by the Welsh bards in the Middle Ages. This neo-Druidic imposture has found numerous adherents, and has been supported with a good deal of mispent learning by several persons of considerable talent. It would be a waste of time to say anything further on the subject here. In Irish poems and tales Druids, and other organized learned classes, are frequently mentioned. From an analysis of these, and aided by whatever light the classical writers throw on the Druidism of Gaul and Britain, we may make the following induction as to their position and organization in Ireland, where they cannot have been very different from what they were in other Celtic countries. There are no definite accounts of the religious rites practised by the pagan Irish, but there are several allusions, which, though vague, plainly show that such rites existed, and that it was one of the functions of the Druids to perform them. The Druids also invoked the divinities in favour of their friends and against their enemies, and for this purpose they made incantations upon a mound or elevated ground near the field of battle. They determined, by auguries from the heavenly bodies, clouds, wind, smoke, the flight of birds, and other phenomena, the propitious and unpropitious times for fighting a battle, or doing any other important action. They announced the *Gaesu* or things which it would be unlucky for a chief or a tribe to do, foretold future events, practised incantations of various kinds, kept events in remembrance, and were, in a word, the depositaries of such knowledge as was possessed in Ireland at the time. Many of these functions belong equally to the persons usually called poets, and among the qualifications of the higher grade of the latter was a knowledge of certain kinds of incantation, some of which involved many pagan rites, the practice of which we find distinctly ascribed to Druids. That the latter were therefore only a higher degree of the order of poets seems certain. As such they naturally performed or superintended all the higher pagan rites, and hence the whole order, of which they were the highest representatives, were called Druids. After the introduction of Christianity the hieratic functions of the Druids ceased, and the term Druid, which had been the special appellative of the poets who performed those functions, gradually fell into desuetude. But the order of which they were the highest exponents did not disappear as it did in Gaul; there its lay functions were swept away by Roman law, whereas in Ireland they acquired new vigour. In pagan times the poets enjoyed great power and many privileges, both of which they are said to have abused to such an extent that it was proposed to banish them altogether out of Ireland. Through the intercession of the mythical king of Ulster, *Conchobar Mac Nessa*, this, we are told, was not done; their number was, however, diminished, and their power and privileges curtailed. Among other changes said to have been then effected was that of depriving the poets of the functions of judge, which they had hitherto performed. This legend indicates the existence at some period immediately preceding the introduction of Christianity of a struggle between the lay and the spiritual power, in which the former were to some extent successful. The struggle continued even into Christian times, for in the 6th century it was again proposed to banish them, but on this occasion they were protected by St Columcille, not, however, without a further diminution of their number and loss of power.

The organization of the learned classes, as we find it described in Irish manuscripts, is no doubt to be referred to the *Dal* or parliament holden at Druimceta about the year 575, at which were present the king of the Dalriadic

or Seotie kingdom, the paramount king of Ireland, and many sub-reguli, and prominent above all St Columcille. According to this organization there were three grades or orders,—the *Gradh Ecna*, the *Gradh Fene*, and the *Gradh Fili*. *Ecna*, wisdom, meant general as distinguished from special professional knowledge. A graduate of *Ecna* was called a *Sai*, sage, but there appear to have been several degrees of the title, the highest of which was the *Ollamh Sai*, sometimes called also the *Rosai*, or very sage, or *Sai léitre*, lettered sage. *Ollamh* (pron. *Ollave*), we may remark, was the title of the highest degree in any profession. An *Ollamh Sai* had the rank and was entitled to the retinue of a *Rig Tuatha*, or tribe king. All questions between the different tribes, the interpretation of the laws, the succession to chieftainships, and similar questions were decided by them. They were the genealogists or historians of the chiefs or kings. In pagan times the *Gradh Ecna*, which was only a branch of the order, call it which we will, of Druids or poets, was probably the highest, judging by the dignity and privilege of its *Ollamh*, and consequently the one whose members were specially called Druids. If this view be correct, it was to this branch that the functions of judge originally belonged. When the right of judgment passed from the Druids into the hands of the *Rig*, or chief, the latter no doubt acted as judge himself, or appointed some one to fill his place. This judge was called a *Breitheam*, or as he is called from the pronunciation of the modern form of the word, a *Brehon*, and was always in early times a *Sai*, for *Fenechas*, or law, formed part of the knowledge comprised under the term *Ecna*, a fact which strongly supports the view above expressed, that the *Sai* was the successor of the Druid. In time the practice of law grew into a distinct profession, and every *Breitheam* of the higher class, that is every one who was a *Sai*, kept a kind of law school. Thus arose the *Gradh Fene*, or lawyers. One of the causes which no doubt helped to separate the study of *Fenechas*, or law, from the general study of *Ecna*, or wisdom, was the rise of schools in connection with religious establishments.

The class of persons whom we have above designated as poets were called *Fili* in Irish, and their art *Filidecht*. The latter is usually translated poetry, but it was rather vaticination in which they used verse. The *Fili* truly represents the *Ováras*, or vates, who formed one of the orders of Druids, mentioned by Strabo. Some of the forms of incantation practised by the *Fili* are described in Irish manuscripts, and, as we have stated above, are attributed to the Druid as well as to the *Fili*. Those which involved pagan rites, and which were consequently forbidden by St Patrick, fell into desuetude with the name Druid; but simple incantations by rhymes continued to be practised in Christian times. One of these, the *Glam Dickinn*, or an incantation of satirical verses accompanied by certain ceremonies, which was believed to be capable of raising blisters on the face, was much used, and supplies, perhaps, one reason of the great sensitiveness of Celts to satire. The *Fili* appears to have been distinguished in early times by some kind of tonsure, the exact nature of which we do not understand. Perhaps it was the same as that afterwards used by the Christian priests, which was one of the causes of difference between the early Irish Church and the Roman Church. It is at all events worthy of remark that the Irish priests were reproached with having the tonsure of Simon Magus, who in those times was the representative of all magicians or others who practised necromancy or vaticination. There were several degrees of the order of *Fili*, the highest being the *Ollamh Fili*, as we have already pointed out. A *Fili* of this rank was entitled to keep, that is, to have supported for him, a greyhound, a beagle, four stallions, two mares, and their foals

—the maintenance of the horses, being we are told, at the expense of the church. The king fostered the *Ollamh's* sons as if they were his own; and the queen was bound to give dowries to his daughters. In return for all these emoluments and privileges the *Fili*, or poet, was bound to furnish a panegyric of the prince annually. In fact the chief function of the *Fili* when he became a mere poet was to eulogize the chief, and the chief's family and ancestors. The designation, given to the Gaulish bards, of parasites who attended the Gaulish warriors on military expeditions to celebrate their praise, by Posidonius the Rhodian Stoic, who visited Gaul about 100 B.C., applies with equal truth to the Irish *Fili*. The flattery was not given without hope of reward, however. In the glossary attributed to Cormac, who was at the same time king and bishop at Cashel in the 9th century, which is at least as old as the 10th century, we are told that the reason why the second degree of *Fili* was called an *Anruth* was because of "the rich stream (*Sruth*) of beautiful praise which flows from him, and the stream of treasures which flows to him in return." This was exactly the sentiment of the Gaulish bard who in eulogizing the magnificence of Bituitus the Avernian chief said, "From the track of his chariot-wheels sprang gold and blessings to mortals." An *Ollamh*, or as we might call him a doctor, in *Filidecht* was entitled to have a certain number of scholars who formed his retinue when he went abroad. One of his privileges was to make a circuit at certain times, the extent of which depended upon his rank. When, for instance, an *Ollamh Fili* became chief poet, and was invested with the *Tugen*, or cloak trimmed with white feathers, the symbol of his office, he might make a circuit of Ireland. During his circuit the *Ollamh Fili* was entitled to maintenance and protection for a certain time, not only for himself but for his legal retinue, and their horses and dogs also. They could not, however, remain beyond the fixed legal time without special invitation. A *Fili*, or indeed any of the recognized learned professions, could not claim hospitality as a right from any one below a certain rank, which was measured by his own.

The bards who recited poems and stories formed at first a distinct branch from the *Fili*. According as the true *Filidecht* fell into desuetude, and the *Fili* became simply a poet, the two orders practically coalesced, and the names *Fili* and bard became synonymous. There were several degrees of bards, according to the number of poems and stories which the graduate should be able to recite. In pagan times, and during the Middle Ages, the Irish bards, like the Gaulish ones, accompanied their recitation of poems on a stringed instrument called a *Crut*, believed to have been a harp. The bard was therefore to the *Fili*, or poet, what the *Jogler* was to the *Troubadour*, and the *Songleur* to the *Trouvère*. The *Cruitire*, or harper, who likewise played upon a kind of Roto called a *Timpan*, and who belonged to the privileged classes, while the players on other instruments did not, was probably the representative of the true bard.

One of the most interesting points in the history of Celtic literature is the relation of the transformed Druidic hierarchy just described to the Christian church. Independent of its own intrinsic interest some knowledge of this is necessary in order to understand the system of schools in Ireland in the early Middle Ages, and the position which the native literature occupied in them. Before stating what we have to say on the latter subjects we must therefore briefly describe the character of the early Irish Church.

The presence of British bishops at several councils, and the production of so distinguished a heresiarch as Pelagius, prove that there must have been an organized church in Britain in the 4th century. At that period there were many populous

The learned classes and the ancient Church of Ireland.

and much of the culture of

a rich Roman province. The British Church must, therefore, have been organized upon the municipal type as in the rest of the Roman empire; that is, the jurisdiction of the bishops must have coincided with the civil government of the Romans, out of which the later diocesan system grew. The intercourse, partly commercial, partly hostile, which took place between Britain and Ireland in the 3d and 4th centuries could scarcely have failed to introduce Christianity into the latter country. Mediæval writers state that Christianity existed in Ireland before St Patrick; and Celestius, the chief disciple of Pelagius, and, according to St Augustine, the real leader of the Pelagians, was an Irishman. Indeed, if we can trust the statement of Genadius, who flourished at the end of the 6th century, the parents of Celestius must not only have been Christians in Ireland in the year 369, but must have known the use of letters, for, according to the writer quoted, Celestius wrote three letters, in the form of little books, on the things necessary for all desirous of serving God. This primitive Irish Church appears to have been principally, if not altogether, confined to the south of Ireland, the province of Munster forming an independent kingdom at this period, or at least one having but little political connection with the other provinces. In after times, when the fame of St Patrick had become established, and he came to be regarded as the sole apostle of Ireland, the saints of the primitive church, many of whose names have come down to us, were assumed to have belonged to the Patrician period, or were confounded with persons of the same name. In this way St Brendan, the voyager, born on the shore of the Atlantic Ocean in the county of Kerry, has been confounded with a later St Brendan who lived in the centre of Ireland. The church which grew up in the south of Ireland, though the offspring of the British Church, must necessarily have adapted itself to the political and social organization of the country, which was altogether tribal, and being without walled towns had none of the elements of municipal government which had moulded the church organization elsewhere. Some of the Irish legendary lives of saints of the early church, though, in the form in which we have them, not older than from the 12th to the 14th century, give us amidst a luxuriant growth of prodigies an insight into this highly interesting church, which the subsequent conversion of the rest of Ireland by St Patrick merely extended, but did not change. When a missionary had converted a chief and his *Occa*, or principal men, he became an adopted member of the tribe, and was considered to be a *Sai*; in other words, he was given the same rank and privileges as the pagan priests had. Beyond building a round wicker oratory for the priest, no change whatever was made in the organization of the tribe. The course of study for the different grades of *Ecna*, *Filidecht*, and *Fenechas* went on as before, except that in the course of *Ecna*, or wisdom, the Christian doctrine was added. The practice of the different kinds of verbal incantation which did not involve distinct pagan rites some centuries later by the poets shows this. Fasting, prayer, and vigils were practised, and those who wished to embrace the ecclesiastical state, that is, to join the new learned class called later the *Gradh Eclasa*, or grade of the church, tonsured themselves, as did the students of *Filidecht* also, as we have before said. The *Dun*, or fortified residence, of the chief, around which lay always a village of the different classes of people who constituted the retainers of an Irish chief, became a kind of *Cenobium* of a novel type. Some members of the *Fine*, or "House," desirous of practising a higher degree of asceticism, went into the march-land, or waste land of the territory, and built a wicker hut and oratory. Others followed, and built their huts all around, and a new *Cenobium*, consisting of a village

of huts and circular oratory gradually grew up, which differed from the original one only by the absence of the ramparts and ditch forming the *Dun*. Afterwards the round tower, which as a mere extension of the circular stone *Caisel*, itself an imitation in stone of a circular wicker-house—afforded a refuge and place of safety for preserving from fire and theft the sacred vessels and books belonging to those religious establishments, which were directly established for religious purposes.

Whether a single *Fine* or the Christian, they were all forming a *Tuath*, or tribe, became of succession to the of the same blood, and the right remained with the property and government of the church within each *Fine* or "House" of the donor. The unit state of the *Tuath*, or tribe, which constituted the ritual *Fine*, or Irish political system, was simply a *spid* only in the "House," and could receive and hold *lanmorb* (coheir), same way as any other *Fine*. Hence the *Coight* be, and or successor of the founder of a *Cenobium*, in the aristocratic frequently was, a layman. This explains, too, the church, who cratic character of the saints of the early Irish Chiefs, as the all necessarily belonged to the families of the *chuses*, or unfree classes could not form *Fines*, or "Houses" to enter those in existence, except by adoption accord among legal forms. When a person of low birth appearing how the saints we are sure to have some legend showing he came to be adopted by somebody. As a consequence of this system all the *Cenobia* which grew out of the first, and the chapels which were established in connection with *Cenobia* to supply the religious wants of distant remote from the latter, remained under the government of the parent establishment. Nay more, the *Cenobia* often founded in neighbouring countries by missionaries did not continued to acknowledge the headship of the parent establishment. They formed, in fact, a religious clan, in which the abbot of the parent establishment exercised the same kind of authority as the head of the ordinary *cl*. In this way it often happened that bishops, notwithstanding the higher order of their functions, were under the jurisdiction of priests, and even of women, as in the case of St Brigit. This peculiar organization of the church continued to exist unaltered in Ireland during several centuries, indeed with few changes, chiefly relating to the position of bishops, down to the Norman Conquest. The Irish carried this organization with them into Wales, Scotland, England, Gaul, Germany, and Switzerland, where it was finally supplanted by the Benedictine order.

When a *Dun*, and its surrounding village, in which lived the various classes who formed the household and retainers of a chief, became a kind of *Cenobium*, in which were associated together those who had formally adopted a religious life and those who had not, we can understand how a school could grow up in which *Ecna*, *Filidecht*, and *Fenechas* should be taught along with Latin and Christian knowledge. But even in the case of *Cenobia* which had a direct religious origin the same thing took place, because many persons of those professions embraced a religious life, and came there with their pupils, either with the object of increasing their own knowledge, or to partake of the literary life of the place. In the 6th century some of those schools had already acquired considerable reputation; while in the 7th and 8th centuries some had grown into small towns, and were much frequented by strangers. Bede tells us that in 664 many of the nobility and lower ranks of the English nation were in Ireland leading a monastic life, or attending the schools, "going about from one master's cell (hut) to another." Incidentally we learn that one of those schools, namely, *Cill Belaigh*, had seven streets of huts occupied by foreigners in the first half of the 8th century. From all this it will be seen that

the teachers in the Irish schools, even when connected with Cenobia, or later with monasteries, were not necessarily ecclesiastics. Indeed some of the most distinguished men who taught in them were laymen, such as Mac Coise, Colman O'Cluasaigh, &c.; and even Flann, surnamed of the monastery, who was head-master of the school of St Buite, now Monasterboyce, in the first half of the 11th century, was a layman and married. This explains the circumstance, so unusual in other countries in the Middle Ages, of so distinguished a scholar as Johannes Scotus Erigena being a layman.

The course of instruction included under the term *Filidecht*, which an *Ollamh Fili* passed through, as laid down in a special tract called the *Leabhar Ollamhan*, or Book of Ollaves, occupied twelve years, eight of which were devoted to learning to read and write the grammar of the Irish language, the laws of the privileged classes, *Filidecht* proper, which besides vaticination, &c., included whatever knowledge was then possessed of the phenomena of nature, the elements of philosophy, *Dinnsenchas* or historical topography, and learning by heart about 270 tales and a number of poems, and the secret language of the poets, &c. The ninth and tenth years were devoted to the composition of various kinds of poetry; the eleventh year was employed in composing fifty major and fifty minor specimens of verse requiring the use of four kinds of metre. The studies of the twelfth year consisted in the composition of six orations, and the study of the art of poetry according to the precepts of four different authors, whose treatises are unfortunately either lost or unknown. The last two years of the course were for those who proposed to become *Ollamhs*. Whatever may have been the character of the teaching or the value of the outcome, it is the earliest example of the cultivation of any vulgar language in Europe. As an example of the importance attached to the native literature, it may be mentioned that the head-master of a school was obliged to go through the course just indicated, as well as to know Latin, "and from the Ten Commandments to the whole of the Scriptures." The school here implied would be one of those connected with a Cenobium, or monastery, and had usually six teachers. The lowest of these taught the students to recite the psalms; the second taught the course of native literature just described up to the end of the 10th year. The fourth master taught Latin, arithmetic, and the elements of astronomy and geography; the fifth master was professor of divinity; and the sixth was the head-master, who was supposed to know the whole course, both profane and sacred.

In discussing the outcome of this system of education we can here of course take cognizance only of what has been written in Irish, and must consequently leave out of consideration the Latin hymns of the early church, the writings of Columbanus, Sidil or Sedulius, Johannes Scotus, Adamnan, and others who wrote in Latin. For the same reason we must in speaking of existing Irish manuscripts leave out of consideration the Latin ones, among which are some of the most remarkable illuminated books in Europe, such as the Book of Kells. In the Ambrosian Library in Milan, the libraries of the convent of St Gall and of Bern in Switzerland, of the University of Würzburg, and of Carlsruhe, there are several Latin manuscripts glossed more or less copiously with explanatory Irish words. There is also in the town library of Cambrai a manuscript containing the canons of an Irish council held in 684, in the middle of which is preserved a fragment of an Irish sermon on self-denial. These manuscripts, some of which belong to the 8th century and the others to the 9th, furnished materials to Zeuss for his *Grammatica Celtica*, a work which created an epoch in Celtic philology. With the exception of the last-mentioned none of these manuscripts contain a con-

tinuous Old Irish text. But according to Mone there is in the convent of St Paul, somewhere in Carinthia, a manuscript altogether in Irish, containing among other pieces poems, copies of which are to be found in manuscripts of the 14th century in Ireland. In the Royal Library at Copenhagen there is one manuscript, partly vellum and partly paper, containing Irish poems, which formerly belonged to Professor Thorkelin, but we do not know its age. The manuscripts formerly belonging to the Irish College at Louvain were dispersed, the better portion being taken to the Franciscan convent of St Isidore at Rome, where they remained until within the last five or six years, when they were brought to the convent of the same order in Dublin. The remainder of the Louvain manuscripts, consisting chiefly of copies of Irish lives of the saints made for Colgan when preparing his *Acta Sanctorum*, are now in the Royal Library at Brussels. These are all the Irish manuscripts now known to exist on the Continent. The Irish manuscripts in the United Kingdom are very numerous, and by good fortune the majority of them, and these the most valuable, are in public libraries, and are thus at once more accessible to scholars and safer from fire, the danger by which Welsh literature has already suffered much loss. The number of Irish manuscripts which formerly existed must have been considerable if the *Fili* were as industrious as they were numerous and well rewarded. More than thirty books are mentioned by special names as sources from which some of the most important existing manuscripts were compiled, which are now lost, although some of them existed as late as the 17th century. Nearly all the most valuable existing books are to be found in four public libraries, namely, those of the Royal Irish Academy and Trinity College, Dublin, the Bodleian Library at Oxford, and the British Museum. The collection of Irish manuscripts belonging to the Royal Irish Academy is the largest of all, and comprises, besides a large number of paper manuscripts containing many things not found elsewhere, the valuable vellum manuscripts, *Leabhar na h-Uidhri* or Book of the Dun Cow, the Book of Ballymote, the Book of Lecan, the *Leabhar Breac* or Speckled Book, the Book of Fermoy. Next in importance stands the collection of Trinity College, Dublin, which contains the Book of Leinster (the most valuable from a literary point of view of all existing manuscripts), the yellow Book of Lecan, and a number of other manuscripts full of poems and prose tales, besides the most valuable of the existing law manuscripts. The collection in the Bodleian Library, though consisting we believe of only sixteen volumes, is very valuable. Besides a rare law manuscript it includes a manuscript compiled perhaps as early as the year 1100, and certainly not later than the first half of the 12th century, and containing some important poems not known to exist elsewhere. The British Museum Library has now a considerable number of Irish manuscripts, chiefly, however, written on paper. But besides some law manuscripts of value, there is one vellum manuscript, a small folio of 68 leaves beautifully written about the year 1460, formerly belonging to Sir Henry Spelman, which contains the best extant copies of several of the most celebrated historic tales. Of the vellum manuscripts in private hands the most important are the Book of Lismore, belonging to the duke of Devonshire, and kept at Lismore Castle in Ireland; a manuscript in the possession of the O'Connor Don, containing a large number of poems of the 15th and 16th centuries; the *Liber Flavus*, a small folio manuscript of about the beginning of the 15th century; the manuscripts formerly belonging to the duke of Buckingham, and now in the possession of the earl of Ashburnham. The most important manuscript in this collection, which is inaccessible to

Existing
Irish MSS.

scholars, is the larger fragment of the Book of O'Duvedan, *Ollamh of Ui Maine*, the O'Kelly's country, who died in the year 1372. The other part of this manuscript is in the British Museum.

Contents
Irish MSS.

The contents of these manuscripts are of the most miscellaneous character, in fact many of them are mere scrap-books. The following classification will enable the reader to form some general notion of the nature of existing Irish literature :—(1) grammar and glossaries ; (2) annals, genealogies, and pedigrees ; (3) history, legendary and real, including a large number of narrative poems, some of which might be considered to be ballads, and prose historical tales ; (4) mythological and other imaginative tales ; (5) lyric poetry ; (6) satire ; (7) religious literature, including lives of saints ; (8) law ; (9) science, inclusive of medicine ; and (10) miscellaneous translations from other languages. The manuscripts containing this varied literature were written after the 11th century ; only three of the principal ones above mentioned are as old as the 12th, the remainder being written chiefly in the 13th and 14th centuries. The contents of a manuscript are at least as old as itself and may be much older. Sometimes the manuscript itself informs us that a particular piece was copied from another manuscript which is named. Again poems are attributed to authors who lived long before the manuscript containing them was written, even as far back as pagan times. Can we look upon those poems as the genuine work of the period they are referred to, in the same way as we accept the works of Greek and Latin writers, although we do not possess any manuscripts of them written within even centuries of the author's time ? and if not, how are we to determine the true age of the contents of an Irish or of a Welsh manuscript ? The answer to this question necessarily affects everything that could be said on the character and growth of Irish and Welsh literature. We must, therefore, say a few words on the subject, especially with a view of pointing out some of the considerations which might help us to arrive at a true solution of the problem.

Use of
letters by
the Pagan
Irish.

The first point which naturally suggests itself for inquiry is whether the Irish knew the use of letters before the introduction of Christianity. This question has been much discussed, but as there is not much evidence one way or the other, the discussion has not been profitable. Cæsar says that the Gauls knew writing and used the Greek alphabet, showing that their knowledge of letters probably came from the Greek colony of Massilia ; and the Gauls of North Italy used the Etruscan alphabet long before the time of Cæsar. But these facts do not necessarily imply that their brethren in the British Islands had also a knowledge of letters before the arrival of the Romans, nor have we any evidence even after that event that the British language was written. The Celtic names on British coins prove nothing one way or the other. As regards Ireland the only piece of evidence of the existence of a knowledge of writing before St Patrick's time is the statement of Geunadius respecting the letters of Celestius. This, it must be admitted, would be very slender evidence to found a conclusion upon unless supported by more definite facts.

Ogam in-
scriptions.

In certain parts of Ireland, and in those parts of Wales once occupied by the Irish, are found rude stone monuments, upon the edges of which are cut inscriptions consisting of a number of long and short lines. This method of writing, which is called *Ogam*, was practised in Christian times even as late as the 9th and 10th centuries, for marginal entries written in *Ogam* characters are found in some of the manuscripts of St Gall ; and in the vellum manuscript in the library of the Royal Irish Academy, called the Book of Ballymote, compiled near the close of the 14th century the different styles of Ogam writing

and the value of the letters are explained in a special tract on the subject. The character of many inscribed monuments, and the circumstances under which they are usually found, seem to favour their pre-Christian use also. On this point, however, there is still much uncertainty, and the utmost that we could venture to say is that the archaic character of the grammatical forms of Ogam words, and especially the case of one bilingual inscription, places their relative antiquity beyond question. The geographical distribution of *Ogam*-inscribed stones is worthy of attention ; they are almost exclusively confined in Ireland to Munster, and chiefly to the south-western counties. In the provinces of Leinster and Connaught only a few have been found at one or two spots, and but one has been found in Ulster ; they are, in fact, most abundant in the district where, according to tradition, the Milesians or Scots first landed in Ireland. In Wales they seem also to be chiefly confined to the districts formerly occupied by the *Gwyddel*, or *Gael*. Notwithstanding the use of *Ogam* by Irish scribes in the 9th century, and the existence of the key in the Book of Ballymote, the deciphering of the inscriptions has not been hitherto very easy, perhaps, as some think, because many are cryptic. Those that have been deciphered with certainty are very simple, and evidently marked the grave in some instances, perhaps in every case, of a *Sai* or *Fili*, that is, if used in pagan times, of one of the Druidic order. If we can trust to the authority of some of the oldest of the romantic tales, *Ogam* was used in the north of Ireland as well as in the south ; there, however, it was cut on sticks or twigs, as Venantius Fortunatus tells us the barbarians cut their runes. In some Irish poems mention is made of *Duille Feda*, which has been interpreted to mean "Books of Wood," and may have been *Ogam*-inscribed tablets. But as no specimen of this literature has come down to us, and as they must, if they were ever used at all, have been an inconvenient and imperfect mode of recording the product of thought, we may leave them out of consideration. Whatever opinion then may be held as to the existence in Ireland of a knowledge of letters in prehistoric times, we may safely assume that literature in the true sense of the word began there with Christianity. In saying this, however, we are not to be understood as denying that a record of events, accounts of battles, panegyrics of warriors, may not be orally transmitted in verse. Metre, alliteration, rhyme, and assonance are powerful aids to the memory, and a bar to the introduction of new matter, and consequently prevent two different streams of traditions from mingling. But in time, and especially among a highly imaginative people possessing the power of improvising in verse, the streams of verse did mingle, enlarge, and modify themselves. Nevertheless it is marvellous how perfectly long poems of the most complex metrical structure may be transmitted by oral tradition for centuries. Poems transmitted in this way follow of course all the phonetic changes of the language, and, when at length they are written down from memory, look as if they had been composed at first in the living language. In this way an essentially pagan literature may come as it were into existence long after paganism itself had passed away. The *Kalevala*, or heroic epic of the Finns, and the *Kalevi Poeg* of the Esthonians, are examples of this. In order that this should take place, the manners, customs, and general state of culture should undergo but little change. When any serious change in these respects occurs, the stream either ceases altogether, or becomes so modified and admixed with foreign elements that a new literature may be said to begin. One of the most marked changes which takes place under such circumstances is the substitution of vague descriptions of dress and arms, and a vague toponomy, for the full and definite descriptions and precise toponomy of the primitive poems.

Oral trans-
mission of
poems, &c.

Oral and written transmission may coexist.

Verse and prose as vehicles for oral tradition.

Changes of language through copying.

IRISH LITERATURE. Grammar and Glossaries.

The knowledge of writing does not necessarily involve the entire supplanting of tradition by written narrative. Many Asiatic nations who possess alphabets from oldest time nevertheless still transmit their history by oral tradition. The account which we have given of the organization and method of instruction of the poets clearly shows that in early times genealogies, laws, history, tales, &c., were transmitted orally, or, as was said, "from mouth and tongue." This should always be borne in mind when discussing the antiquity or genuineness of poems, prose tales, or histories. Here it may be well to remark that verse is a better vehicle for the oral transmission of knowledge than prose. Besides being more difficult to remember than verse, prose offers greater facility, not to say inducements, to introduce new matter by way of explanation or commentary, or to fuse legends of different kinds. Hence laws were transmitted in verse, and wherever we have a legend embodied in verse, it will be found to be both more archaic and purer than when in prose. The use of prose seems to indicate the passage from oral to written tradition. Another point which should be kept in view in judging of such literatures as those of Ireland and of Wales, is that after the traditions of a country have been committed to writing the different kinds of knowledge will not be transmitted in equal purity or preserve their original form and language equally. Every fresh copy of an account of a battle, a legend, or a life of a saint, or of a narrative or description, would follow the change in the spoken language, and to some extent in the accessories of the picture, such as dress, arms, &c.; in other words it would be a new and popular edition made intelligible to all. On the other hand, the exact words of a law or decision are important and would be sure to be copied without other changes than what the carelessness or ignorance of the scribe would produce. As vellum was dear and not easily procured everywhere the words were written close together and contractions were used, especially for the terminations; here was a fertile source of error and of the corruption of grammatical forms by ignorant and careless scribes. The most cursory examination of Irish manuscripts will illustrate the preceding remarks. In the same manuscript may be found pieces which differ in language by centuries. If the manuscript contain law-tracts, or pieces on subjects not of common or popular interest, they will be found written in obsolete language, and generally noted with explanatory glosses or commentaries. The language of the tales and popular poems on the other hand will represent exactly the period of the compilation of the manuscript; and yet they may have been originally composed long before the law.

We need not dwell on the first category of Irish literature further than to observe that Irish scribes seem to have had a special liking for glossing, and that if all the existing glossaries, old and new, were added together we should have at least 30,000 words besides those in printed dictionaries, a richness of vocabulary unequalled perhaps by any living language. Among the old glossaries we may mention that attributed to *Cormac Mac Cuilemáin*, king and bishop of Cashel, who was killed in 903, as an early attempt at comparative etymology, the author referring to Latin, Greek, Hebrew, Norse, and British. Many of these derivations are no doubt wrong, but as an early attempt it is curious. The earliest copy of this glossary is to be found in the Book of Leinster, compiled in the first half of the 12th century, but though some articles may have been added, there is no reason to doubt that it was the work of Cormac. As grammar formed an important subject of the course of *Filidecht* we might expect to find many treatises on it in Irish manuscripts. Several are mentioned, but they appear to be lost. There is, however, one deserving of much attention, written perhaps in the 9th or 10th century;

the oldest copies now known, however, are these in the Books of Ballymore and of Lecan, manuscripts compiled towards the end of the 13th century.

Annals form a notable element in Irish literature, but we can do little more than mention a few of the more important compilations. During the 11th century attempts were made to synchronize Irish events with those of other countries. Of these may be mentioned the synchronisms of *Flann* of Monasterboice, already mentioned. But the most notable attempt to synchronize events is that made by *Tighernach O'Braoin*, abbot of Clonmacnoise, who died in 1088. *Tighernach* in his Annals displays considerable scholarship, and for the time fair critical power. He was probably the first to introduce the common era into Irish annals. The oldest copy, and unfortunately only a fragment, is in a manuscript of the 12th century in the Bodleian Library at Oxford, nor can a perfect copy be made out of the six or seven other copies which are known. The Annals called by most writers since the times of Usher and Ware the *Annals of Ulster*, but more correctly the Annals of *Senat Mic Maghnusa*, or Mac Manus, compiled or copied by Cathal Maguire in 1498, in an island in Upper Lough Erne called *Senat Mic Maghnusa*, and continued in some copies to 1604, are of special importance, because the book contains notices of comets, eclipses, and other natural phenomena, which appear to have been recorded by eyewitnesses, as is proved by the day and hour of the eclipse of the sun on 1st May 664 being correctly recorded, while Bede, who records the same eclipse post-dates it, as the result of calculation, by two days, as does the Saxon Chronicle also. *Tighernach*, like the *Annals of Ulster*, gives the right date. This fact shows that both *Tighernach* and the compiler of the *Annals of Ulster* must have had access to contemporary documents, at least as old as the middle of the 7th century. But the most extensive though the latest-compiled Annals is the collection called by Father John Colgan, editor of the *Acta Sanctorum Hiberniæ*, the Annals of the Four Masters, the chief of whom was Michael O'Clery, a Franciscan friar, who, after collecting materials from the then existing Irish manuscripts, commenced in 1632, amidst the ruins of the convent of his order in Donegal, the compilation of this very remarkable monument, and in four years completed it. The Annals of the Four Masters extend from fabulous antiquity to 1616. Down to the 4th century the entries are little more than lists of kings, but thenceforward they become fuller and more trustworthy.

The political and social organization of Ireland, and especially the custom of gavel-kind, made pedigrees and genealogies matters of great importance. The Irish genealogies are usually carried up to Noah, and include on the way many eponyms and even divinities. The Biblical portion may be easily removed without detriment to the Irish part; but it is not so easy to say where the legendary and the true touch. Within the historical period the pedigrees and genealogies afford great help in historical inquiry, though it should not be forgotten that a *Sai* was quite as capable of inventing a pedigree as any modern herald. Topography may be said to be the complement of pedigrees, and like the latter was of great use to Irish genealogy. families, and was accordingly, as we have already pointed out, well attended to. Of this kind of literature the most curious and valuable example is the tract called the *Dinnsenchas*, said to have been compiled at Tara by a *Sai*, named *Amergin Mac Amalgaidh*, or Macaulay, about the year 550. This work, the oldest copy of which is in the Book of Leinster, gives an account of the legendary origin of several places of note, and thus preserves invaluable mythological materials.

Historical poems.

Every successive race which peopled Ireland had, we are told, its historian, whose names are given, and in some cases particular verses and even long poems are attributed to them. These are, of course, mythological personages, but this fact is in itself a proof of the antiquity of the system of recording in verse the history of the country. Without going back to *Coirbre*, the son of the goddess *Etain*, wife of *Ogma* "of the sun-like face," a long list of poets beginning with *Ailill Olum*, a king of Munster in the 2d century, the supposed progenitor of the chief Celtic families of the south of Ireland, may be made out. There are three poems in the Book of Leinster attributed to the *Ailill* just named. It is needless to say that in their present form these poems could not be the work of a poet who lived a thousand years before the Book of Leinster was written, even if the poet were not, as is probable, only an eponymous ancestor of Munster clans. To the same or a somewhat later period belong several other mythological personages to whom poems still extant are attributed, and of whom we shall have something to say presently,—namely, *Finn* son of *Cumall*, contemporary of *Cormac* son of *Art*, "the lone man," and a reputed author himself, *Oisín* the son of *Finn* (the Ossian of later romance), and his brother *Fergus*, and his cousin *Cailte*. In *Níall* of the Nine Hostages, who was killed on an excursion into Britain in 405, we have probably an undoubted historic personage, and in *Torna Eigeas* or "the learned," his *Fili*, a real poet. There are many poems attributed to him still extant, but in their present form they belong to a period not perhaps earlier than the 11th century. His contemporary *Laidcenn* was the author of an Art of Poetry which has not reached us. After the conversion of the whole country in the 5th century there cannot be any doubt that the poets whose names occur in the Annals, and to whom poems are attributed in manuscripts, were real personages. Some of the poems attributed to the earlier ones have come down in such an archaic dress that it is probable we have the genuine work of the poet. The works of the poets of the 9th, 10th, and 11th centuries are either their genuine productions or at most slightly modernized versions. Between the first of those centuries and the 14th the change in the language was not very great. Among the names of authors of historical poems who lived between the 5th and the 11th century the following deserve special mention:—Bishop *Fiacc*, author of a metrical life of St Patrick which survives nearly, if not quite, in its original form; and *Dallan Forgaill*, a contemporary of St Columcille, and author of an elegy on that saint, which is to be found in the oldest manuscript written wholly in Irish now in Ireland, the *Leabhar na h-Uidhri*, or Book of the Dun Cow, which was compiled before 1106. The poem in question is glossed and accompanied by a kind of commentary on the difficult words, so that the language was already so obsolete in the end of the 11th century as to be practically unintelligible. In the 7th century the most prominent names are the following. *Senchán Torpeist*, the successor of the *Dallan* just mentioned as chief poet of Ireland, flourished about the year 600. *Senchán* is one of those to whom the authorship of the existing form of the principal Irish tale, the *Táin Bó Cuailnge*, is attributed. *Fintann*, poet of *Raghnallach*, king of Connaught, killed in 648, has attributed to him the authorship of a very spirited ballad on the deeds and death of his patron. The language of this poem, admitting it to have been written by *Fintann*, has been modified to some extent in the way above suggested. *St Moling* was the author of several poems of considerable merit, some of which only come under the present category. Two of *St Moling's* poems have been found by Mone in the manuscript in the convent of St Paul in Carinthia above mentioned, and scarcely differ in

orthography from the copies which exist in manuscripts in Ireland compiled six hundred years later than the St Paul codex, assuming the latter to be, as Mone suggested, of the 8th century. *Cennfaeladh* "the Learned," the reputed author of the grammar of the Irish language above mentioned, died in 678. During the 8th century the number of writers appears to have been smaller than in the preceding and succeeding centuries. This was no doubt due to the great number who went abroad, for during that century, and the early part of the 9th, Irishmen were to be found in every part of Europe. In the latter century *Fothadh*, *Flanagan*, and *Flann Mac Lonáin* occupied a prominent position as writers of historical poems. *Laitheog*, the mother of *Flann Mac Lonáin*, deserves mention also as a poetess, and as showing that women shared in the literary cultivation of the period. In the 10th century the most prominent poets were *Cormac* "the Learned," *Cináedh O'Hartagan*, and *Echaid O'Flinn*; and in the 11th century, *Echaid O'Ceirín*, surnamed "the Learned," author of a curious historical poem descriptive of one of the great fairs or *Oenechs*, held in Ireland; *Mac Liag*, *Mac Coise*; *Cuan O'Lothcain*, and *Flann* of the Monastery. The historical poems attributed to the writers of the 10th and 11th centuries are, as might be expected, much more numerous than those of preceding ones. Indeed we might make an epitome of the whole history of the country, especially of the legendary part, from the poems of the writers just mentioned, the poets of one period deriving the materials of their own poems from those of their predecessors.

In the 11th and 12th century prose came largely into use, as is shown by the large number of prose historical tales and romances which were written at this time. It is difficult to draw a line between real history and historical fiction in an early literature, but in Irish it is especially so, for we find many of the so-called historical tales so free from the miraculous, and so sober in the narrative, that at first sight we could scarcely refuse to accept them as history; and yet one of them to which this description applies is undoubtedly an account of a war between deities. In general, however, we can follow all the stages from a simple historical narrative up to a full-blown romance. The circumstances under which this kind of literature was produced show why this should be so. The business of the *Fili*, or poet, was to praise his chief, celebrate the achievements of his ancestors, and find him amusement when he regaled his *Sabaid*, or props, as the chief men of the tribe were called, in his alehouse. For this purpose a simple narrative of a foray or a skirmish required to be embroidered with a little romance; hence the number of accounts of battles, deaths, feasts, &c., which though in the main founded on real events belong by their treatment to fiction. There are, however, some productions which though not free from invention may yet be classed as attempts at writing prose historical narrative. Perhaps the earliest of this class of compositions is the History of the Borromean Tribute, or great tribute of cows levied in the province of Leinster by *Tuathal*, surnamed *Teachtmar*, or "the Legitimate," whose death is variously stated to have occurred at from 106 to 160, and who consequently belongs to the dawn of the historic period. This tribute was abolished by the paramount king of Ireland *Finnachta*, surnamed "the Festive," at the instance of the *St Moling* above mentioned, but imposed again in the beginning of the 11th century by *Brian*, surnamed from this circumstance *Boroimhé*, or "Brian of the Cow Tribute," as a punishment of Leinster for supporting the Danes. This interesting work is found in the Book of Leinster, and was therefore probably written at the time of the re-imposition of the tribute. Another work of the same period is the Wars of the *Gaedhil* with the *Gaill*, or the

history of the invasions of Ireland by the Danes and Norsemen. The only perfect copy of this work known is one in the handwriting of Michael O'Clery, chief of the Four Masters, in the National Library at Brussels, but there is a fragment of it in the Book of Leinster, the remainder being lost. The existence of this fragment shows that it was written at latest within a century of the battle of Clontarf; but from curious incidental evidence it must have been written by an eye-witness of the battle, or by some one who received his information from one who had been there. It is mentioned in the history that the tide in Dublin Bay coincided with sunrise on the 23d of April 1014, the day the battle of Clontarf was fought, and that the returning tide in the evening aided in the defeat of the Danes; astronomical calculations have shown that the first part of this statement is quite correct. The style of this work is poor, the descriptions are wanting in precision and accuracy of detail, owing to the redundancy of nearly synonymous adjectives, and it was evidently written by a partizan of Brian. But with all its faults it is a work of some interest even from a literary point of view. The Wars of Turloch, written by John Mac Grath, historian of the Clans of Thomond, now the county of Clare, about the year 1459, is a third example of historic prose, and one which gives us an insight into the nature of the feuds and struggles for power between rival claimants for a chieftancy, and the part which the Norman adventurers played in these intestinal contests, which ultimately allowed them to become masters of the country. The immediate subject of the history in question was the war between Turloch O'Brian and his uncle Brian Ruadh O'Brien, and the sons of the latter, aided by the De Clares; but it may be said to be a history of Thomond for more than two hundred years, from the Anglo-Norman invasion to the death of Robert de Clare and his son. Like the work last mentioned the style of this history is very redundant, the descriptions being overloaded with adjectives almost identical in meaning, and often incorrectly applied; it is not, however, devoid of skill in the narrative, and many of the incidents are described with vigour and force. Perhaps if we had the original texts of this and the Wars of the *Gaadhil* with the *Gaill*, we should find the style purer. One of the ways in which scribes corrupted the texts of the works they copied was by adding meaningless adjectives to give as they thought dignity and ornament to the descriptions.

The Book of Munster, though of uncertain date, and not known to exist in any old manuscript, is a work which illustrates very well the peculiarities of Irish historical compilations. It begins with an account of the Creation taken from Genesis, which serves as an excuse for tacking on the Biblical genealogies to the Irish ones; then follows the history of the Milesians from Eber, son of Miled, the eponymous ancestor of the Munster tribes, to Brian Boroimhe. The legendary part of the work is to be found in most of the principal Irish manuscripts; but the part relating to the period from the 7th to the 10th century is of great interest, and contains much not found elsewhere. The ethnic legends just referred to, which form so prominent a feature in Irish historical compilations, have been all brought together in what is called the Book of Invasions. This work is a link between genealogies and historical narrative proper, and consists of the legendary histories of the successive tribes supposed to have peopled Ireland, and of their eponymous leaders, into which are introduced many curious so-called historical poems, the matter of which, if not the language, is of considerable antiquity. The oldest copy of the Book of Invasions, the author of which is not known, is that in the Book of Leinster; the one which existed in the Book of the Dun

Cow in 1631 has been unfortunately since lost, with much of that valuable manuscript. Michael O'Clery, chief of the Four Masters, compiled from the copy just referred to and others, a condensed version, the original of which is now in the possession of Lord Ashburnham. In speaking of the Book of Invasions we are reminded of the first attempt made to write a general history of Ireland, by Geoffrey Keating, a parish priest in the county of Tipperary, in the beginning of the 17th century. His work, which is written in the spoken Irish of the period, and compiled under very unfavourable circumstances, is an epitome of the copious mixture of legend and fact which is found in Irish manuscripts, and among other things contains much borrowed from the Book of Invasions. He appears to have had access to many manuscripts since lost, and though he makes no attempt to examine his materials critically, the work has considerable value, and bears comparison with similar attempts made under analogous conditions in other languages.

The learning of stories formed, as we have seen, an important feature in the course of *Fili*decht. An *Ollamh* ^{Different classes of tales.} *Fili*, for example, was bound to know two hundred and fifty prime stories, and one hundred secondary ones. In the 11th and 12th centuries the number of stories current must have been very considerable. There is a list of one hundred and eighty-one tales in the Book of Leinster classified under the heads—Destructions, Cow Spoils, Wooings, Battles, Adventures in Caves, Wanderings and Voyages, Deaths or Tragedies, Feasts, Sieges, Adventures, Abductions, Slaughters, Irruptions of Lakes, &c., Visions, Loves, Expeditions, Marches or Progressions. More than one hundred of these are still extant, and of these nearly one half are to be found in manuscripts as old as the 12th century, into which they were copied, as in many instances we are distinctly told, from older books. The existing tales belong to six categories:—(1) ethnic, or those relating to the peopling of the country, and the subsequent struggles of the different races; (2) voyages, expeditions to Scotland, the Isle of Man, or Britain, and the sieges, battles, adventures, deaths, and abductions which took place there; (3) mythological stories connected with the *Síde*; (4) tales forming the heroic cycle of Queen Medb and Cúchulainn; (5) the tales of the Fennian or Oisianic period; and (6) miscellaneous tales belonging to pagan and Christian times, but chiefly to the periods of the 3d and 7th centuries.

The Book of Invasions is simply an attempt to put Ethnic the principal stories of the first category into a methodical order. The staple of the stories of this class is unquestionably of considerable antiquity, though in the present form they are not much older than the 12th century. Of the existing ones the most important are the accounts of the battle of *Mag Tuired Conga*, supposed to have been fought between the *Firbolgs* and the intrusive *Tuatha Dé Danann*, and the battle of *Mag Tuired* of the Fomorians, supposed to have been fought between the latter and the *Tuatha Dé Danann*. The first of these tales has the terseness and simplicity of a Norse Saga, and depicts a rude and early state of society wholly unlike that in the later stories. The supernatural is so little developed in them that, notwithstanding the chief personages are the gods of the Irish pantheon, they must represent real ethnic struggles.

The stories we would propose to place in the second category have little in common save that they refer to what we might call the prehistoric relations of Ireland with Britain. Some relate to personages of the heroic or mythological cycles; others to Scotie invasions of Britain; and others again to the Christian Dalriadic kingdom. Of the tales of this second category two are of great value in the history of romance—namely, the Abduction of *Blathnad* ^{Legends of early intercourse with Britain.}

daughter of *Paill* by *Cúchulaind*, and the Voyage or Exile of *Breccán*. The *Paill* of the first story appears to be the *Paul* of the Welsh *Mabinogion*, which we shall mention further on; and in her second husband we have the *Corroi mab Dayry* of a Welsh poem, which gave rise to much discussion. The *Breccán* of the second story was, according to Cormac's glossary, the son of *Niall* of the Nine Hostages, one of the Scotie invaders of Britain, who traded with a fleet of fifty boats between Ireland and Alba, but was wrecked, and he and his whole fleet lost, in a whirlpool formed by the meeting of the tidal currents in the channel between the two countries, which on this account was called *Coire Breccáin* or *Breccán's* cauldron. Dr Reeves thinks this was between the mainland of Antrim and the Island of Rathlin; but it has since migrated with the legend to the channel between Jura and

"Scarba's Isle, whose tortured shore
Still rings to Corrievekan's roar."

Breccán has also left footprints of himself not only in Welsh legend but also in Welsh hagiology, and as we have already mentioned in Welsh toponymy, for he is the *Brychan*, the founder of one of three families of saints, who has given his name to Brecknock.

Mythological tales.

The mythological tales all relate to the inhabitants of the *Side* or Celtic Elysium, whose chiefs were the mythical *Tuatha Dé Danann* leaders, and who form, as we have pointed out above, an extensive pantheon. Among those who figure in the tales are *Etain*, *Lêr*, *Manandan* his son, the *Dagda*, *Tuirenn Bievern* or *Delbaithe* and his three sons, and *Lug Mac Eithlenn*. These tales may be divided into three classes. In the first of these the actors are all *Tuatha Dé Danann*, or these associated only with personages of remote antiquity, and in the second the same divinities are associated with personages of the heroic period, especially with *Medb* and *Cúchulaind*, and those in which historic or semi-historic personages are associated with the deities of the *Side*. The Wooing of *Etain*, the Exile of *Bri Leith*, the Death of the Sons of *Tuirenn*, are examples of the first class. The *Seirglige Conchulaind*, or Bed of Decline of *Cúchulaind*, one of the most remarkable of all the Celtic mythological tales, is an excellent example of the second. The third class embraces such tales as the Wooing of *Becuma* by *Conn* "of the Hundred Battles," and the Adventures of *Conndla* the Beautiful, son of the *Conn* just mentioned. In the third class might also be placed a number of curious tales in which pagan myths are transformed into Christian ones. We may observe this transformation of the pagan into the Christian myth in every stage of the process; thus in the tale called *Tomaidm Locha Eachach*, or the Irruption of Loch Neagh, or, as it is called in the *Leabhar na h-Uidhri*, *Aided Echach Mac Mairéda*, the Death of *Echach* son of *Mairéda*, we have a legend more than half of which is pagan, but which in the latter part is changed into a Christian myth without affecting the general pagan character of the whole. The Fate of the Children of *Lêr*, or *Lear*, is a legend of the same kind; indeed the same pagan myth serves as the basis of the Christian part of the myth in both tales. In the Birth of *Aed Slane*, king of Ireland, who died in 600, we have an Aryan myth completely transformed into a Christian one. *Diarmait*, son of *Cerboil Aed's* father, had two wives, *Murend* and *Murgán*, the former of whom was bald, and was provided with flowing hair by the aid of St *Ciaran*, or *Kyran*; the latter was barren, but becomes fruitful through the aid of St *Finden* and of a bishop named *Aed* (fire, spark), who gives her a drink of blessed water which renders her pregnant of a lamb; a second drink causes her to bring forth a silver salmon; but the third drink gives her a son called *Aed*.

There is a special class of legends, the *Immrans* or

Wanderings by sea, which we have not included in any of the foregoing categories, but which, as examples of the fusion of pagan and Christian elements in a legend, may be disposed of here. The origin of the Christian *Immrans* is to be found in several pagan tales such as the Visit of *Conn* "of the Hundred Battles" to the Land of Promise, which forms part of the Wooing of *Becuma*, already mentioned. The principal *Immrans* are—the Voyage of St Brendan (the most celebrated of all), the Wandering of the sons of *Ua Corra*, and the Wandering of *Maeldun*. In these the transformation of the pagan myth is so complete that we should not have been able to trace their origin but for the existence of the pagan tales just mentioned.

There is another class of compositions—the *Fisa*, or *Fisa*, or Visions, which, though strictly belonging to the category of religious literature, offer so many analogies to the *Immrans* or Wanderings, in some of the incidents, that it is better to say a few words on them in this place. In several pagan tales we have examples of visions, some brought about by pagan rites, which are the prototypes of the later Christian visions, such as those of St *Adamnán*, and St *Fursey*. The Christian visions of Hell and Heaven owe something to Virgil, but the extent of the obligation is much smaller than might at first sight be supposed, for we can trace the growth of the ideas under which the *Fis* or vision was evolved and developed to the fusion of pagan, Celtic, and Christian notions. Several of the adventures of Brendan, *Maeldun*, and the sons of *Ua Corra* contain scenes which have the same origin as many of those depicted in the visions.

The tales which we propose to include under the head of Heroic tales form a large and well-marked epic cycle. The central tale of the series is the *Táin Bó Cuailnge* or Cattle Spoil of *Cuailnge*, now Cooly, in the county of Louth, which relates the history of the war waged by *Medb*, queen of Connaught, the Queen Mab of fairy mythology, and her husband *Ailill*, with *Conchobar Mac Nessa*, king of Ulster, for the possession of the mystic brown bull of *Cuailnge*, in which the hero *Cúchulaind* defends Ulster single-handed, while the king and his champions are in a peculiar state of debility inflicted upon them for a savage act of the former. The existing tales of the series amount to about thirty, exclusive of the tale of the *Táin* itself and of the prologues and fore-tales narrating the preparations for the great cow-prey. In these tales as a whole we have one of the most complete epic cycles in any literature. We have a narrative of the life of the great hero of the series from his conception to his death, of *Medb*, the chief heroine, and of all the chief personages on both sides, male and female—*Conchobar Mac Nessa*, *Fergus Mac Roigh*, *Ailill*, husband of *Medb*, *Conall Cernach* and *Lóiguire* or *Leghaire Bnadach*, companions of *Cúchulaind*, the sons of *Uisnech*, and *Ferdiad*; *Deirdriu*, *Emer*, and the other women who take part in the action. In some of the stories *Guroi Mac Daire*, the Munster king, *Conaire Mór*, the paramount king of Ireland, *Manandan Mac Lir* and his wife *Fand*, and many other personages of Celtic mythology come in. The principal tales of this remarkable series exist in manuscripts written in or before the early part of the 12th century, and the others in vellum manuscripts of good authority. The stories are mixed prose and verse, the latter being generally more abundant in the oldest copies; the finest episode of the *Táin* itself, descriptive of the single combats between *Cúchulaind* and *Ferdiad*, consists of about equal parts of both. Prose, as we have said above, marks a transition period, and it is therefore likely that the whole series originally consisted of poems which the bard in reciting introduced by brief prologues which served to connect the subjects of the several poems into a kind of connected narrative. This may be regarded as the first

stage in the composition of national epics, that is, when the isolated poems fashioned by different rhyme-smiths are first welded into some kind of connected whole. A second stage would be the linking together of the separate episodes by a permanent setting of prose which would connect, continue, and expand the stories of the separate poems into a continuous coherent narrative. A third stage would be the forging of the whole material, poems and prose settings, into one continuous epic poem. The elder Edda, which consists of thirty-eight poems collected from the mouths of the Skalds, perhaps in part composed by Saemund Sigfusson, towards the end of the 11th century, gives us the first or embryonic stage of growth. Snorro-Sturleson's prose Edda, made in the beginning of the 13th century out of the poetic Edda and other materials, gives us a second stage; and after a long interval a third stage was reached in Oehlenschläger's *Nordens Guder*, or "Gods of the North." In this case the original materials underwent complete fusion in each stage. The *Iliad* and *Odyssey* of Homer are examples of epics in a third stage, but we do not know their previous stages. The Finnish Epic, *Kalevala*, made in the present century shows us that an epic may be fashioned directly from the popular poems without passing through a prose stage at all. The *Táin Bó Cuailnge* is clearly in the second stage, a fact which should not be forgotten in comparing it with other national epics, as for instance with the Nibelungen Lay, which is an epic in the third stage. But the Irish epic not only belongs to a different stage of poetic workmanship, but, owing to the comparatively isolated position of Ireland, to a relatively much earlier and more archaic type of society than that of the German epic, which moreover was recast, or at all events reached its third stage in the 12th century in the times of the brilliant Hohenstaufen.

Who the author of the *Táin Bó Cuailnge* or of any of the tales of the heroic period was is not known. A curious legend points to *Senchán Torpeist*, a poet who flourished about 600, as the person who gave the *Táin* its present form; another tradition assigns the work to St *Ciarán* of Clonmacnoise. The language of the portion of the *Táin* in the Book of the Dun Cow is not older at most than the beginning of the 10th century; the text of the Book of Leinster, which contains the whole story, is more modern, although the two manuscripts do not differ in age perhaps fifty years, the language of each copy evidently following, as we have before pointed out, the current of the spoken language. The tales of the heroic cycle, whenever originally written, are essentially pagan, and represent an early state of society still unaffected by Christianity or by Roman influence. That real persons may become the heroes of legends, and very simple everyday acts the roots of myths, is too well known to require proof. Indeed, it may be doubted whether a real personage may not always be necessary as a lay figure for the myths to gather round in the first instance. Be this as it may, *Cúchulaind*, *Medb*, and the rest of the personages of the heroic period, notwithstanding their complete anthropomorphism, are a phase of Irish mythology. The connection of the *Tuatha Dé Danann* pantheon and the actors in the heroic tales is direct and explicit. Thus the rival bulls, which are the direct cause of the war, are but metamorphoses of two hostile personages among the inhabitants of the *Síde*, the representatives perhaps of the Teutonic *Æsir* and *Vanir*. *Fledelm*, the *Ben Fáth*, prophetess, from the *Síd of Cruachan*, appears to *Medb* and describes to her *Cúchulaind*; *Balb*, the *Mór Rúg*, forewarns *Cúchulaind* of his death; the latter in the tale of the Bed of Deeline, which we have referred to in speaking of the mythological tales, is bewitched by the woman of the *Síd*; *Fand*, wife of *Manannán Mac Lir*, falls in love with him; he visits *Tír Tairngire*, or

the Land of Promise, and assists the people of the *Síde* in a battle against their enemies. *Medb*, too, has power over the *Geiní Glinde*, or Spirits of the Glen, and in many ways shows her divine nature.

The poems and tales which we have called Fennian, or Oisianic, form a cycle entirely distinct from the heroic one. Their history, too, is curious. *Finn*, or *Fínd*, the son of *Cumall*, the chief hero of the tales, is supposed to have flourished in the second half of the 3d century and to have acted as commander of a body of mercenaries. He therefore lived at a time which may be considered, if not actually within the historic period, at least upon its threshold. The struggle of the various races for mastery was ended, and this militia or standing army was evidently intended to keep the subject races in check. That the idea of such a force was suggested by the Roman army in Britain there can be little doubt. Perhaps to the existence of this body is due the considerable scale upon which the subsequent invasions of Britain by the Scots took place. As *Finn* appears in the accounts of the battles which he is supposed to have fought, he has all the air of an historical character, and is almost entirely devoid of legendary accessories. The same may be said of his son *Oisín*, the poet, and of his grandson *Oscar*. In the Book of Leinster are two poems ascribed to *Oisín*, and only two or three tales belonging to the Fennian cycle—one of which has reached the present time—are mentioned. Indeed in the older manuscripts there are few references to *Finn*, or to any of the personages of the Fennian romances. In the 12th century it would appear, therefore, that *Finn* and the other Fennians had only just begun to become the heroes of romance. But between the end of the 12th and the middle of the 15th century a rich body of poems and tales came into existence. This new Fennian epos possessed considerable vitality, for it continued to grow even down to the present century, and at least one entirely new tale belongs to the 18th century, and many received considerable expansion during the same time. The cause of this very remarkable growth of legend is obscure, and would be well worth investigating in connection with the history of romance. The two streams of romance are perfectly distinct and never mingle; at least we never find any of the heroes of the heroic period mentioned as actors in genuine Fennian tales. No better proof of the spurious character of a legend could be given than the co-existence in the same poem or story of actors belonging to the two romantic cycles.

The Fennian or Oisianic legends are very numerous and very romantic, and there is a distinct Fennian toponymy, which has not obscured or invaded that of the heroic period. *Finn* is still a popular hero, while *Cúchulaind* has become a shadow. In the current Fennian literature, as distinguished from the mere corrupt popular plastic legend on the one hand, and the Fennian poems and tales contained in good manuscripts of the 15th century on the other, there is an increasing disregard of relative chronology, and of consistent toponymy. There is not the same terseness and clearness of expression in the new as in the old stories; they are evidently the work of a people who are no longer in the same stage of culture. The descriptions of the dress and arms of the actors are vague, the number of those slain in battle is greater. The romances of the 14th and 15th centuries are full of magic and wild prodigies, but nevertheless they have the aroma of the forest and the mountain heather; one hears the echo of the huntsman's horn, and sees the rude life of the *Dun*, and the deep drinking of the chief's ale-house. The prose tales lack the refinement of the Welsh *Mabinogion*, and the poems the polish of the Welsh ones, but they are truer products of the national culture of the period.

Fennian
Oisianic
tales.

The sixth or miscellaneous class of legends do not require special notice, the more so as we have already included among the mythological tales some that might come under this head. Nor do the limits of this article permit us to say anything on the subject of lyric poetry. We have spoken of the incantations in verse of the *Fíle*, and of the satirical poetry which originated in them, and which for a long time was endowed by the popular mind with baneful powers. This belief was the source of the *Fíle's* influence in Christian times, and encouraged him to indulge in satirical compositions. Some of these possess considerable merit, and two of them deserve to be specially mentioned as early examples of a form of satire which was used by the French writers of *fabliaux*, and which in the hands of Rabelais and Swift gave rise to great works. The first is the *Aislinge* or Phantasy of a certain *Aníer*, the son of *Conglinn*, who lived at the end of the 8th century. He was at first a theological student, but soon relinquished divinity for satire and the free life of a *Fíli*. He betook himself to Cork, to *Cathal*, king of Munster, who happened to suffer at the time from the disease of a voracious appetite, for which he sought everywhere a cure. *Aníer* undertakes it and succeeds. The piece opens with a kind of prelude in which a northern hag boasts that *Maeldun*, king of *Ailech* in Ulster, *Cathal's* rival for the paramount sovereignty of Ireland, is about to go to the south and carry off its spoils; a southerly hag defies him, and says he will stop on the way. The poet, as if to raise his own importance, gives in a short poem the names, tribes, and places of eight scholars of repute, among whom is of course the poet himself, who had studied together at the school of Armagh. Having thus given himself the necessary importance, he describes his preparation for his journey to Cork, and the journey itself. On his arrival there he goes to the guest-house of the Cenobium, but not finding it an agreeable place, and the food being not to his liking, he writes a severe satire on the place, for which he is treated badly by the abbot. *Aníer* revenges himself by writing a singular genealogy of *Manchan*, the abbot, whose ancestors up to Adam he represents to be various forms of luxurious viands. He then acquaints the abbot with his object in visiting Cork, and relates a vision which he had of an island of wheaten bread in the midst of a lake of new milk, on which was a house of butter and other articles of food. He fancies himself ferried over to this island in a boat of beef, and finds at the house a singular doorkeeper dressed in clothes of beef, curds, fish, butter, &c., and ornamented with garlands of sausages. Here he learns how to cure his voracious appetite, which he feigns to be the object of his search. The result of this account of his vision is that *Manchan* sends him to the house of a certain *Píchan*, where he has an interview with king *Cathal*, and relates to him another vision of a mansion made of the most delicious viands, with the object of enticing the *Lonchraes*, or voracious demon, with which the king was supposed to be possessed, to come forth. By such stratagems he ultimately succeeds in enticing the demon out, and curing the king. The personification of viands in this curious piece forcibly reminds us of the French *fabliau* of the *Bataille de Karesme et de Charnage*,¹ in which the combatants on one side are fish and the various dishes permitted in Lent personified, and on the other the various kinds of flesh meats.

The Dream or Phantasy of *Aníer Mac Conglinn* is in a manuscript, of about the year 1400, called *Leabhar Breac*, the Speckled Book, but the language of the piece even in its present state proves that it is much older. There seems, indeed, no reason to doubt that it really was written in the 8th or 9th century, and that the orthography has been

only a little changed by the scribes who copied it. The contrast between the dishes, the mere recital of which it was hoped would entice the demon from *Cathal's* stomach; and those mentioned in the French *fabliau* are very instructive as regards the kinds of food in use, and the relative degree of skill in the culinary art, and the general culture of Ireland and France at the periods when the *Aislinge* and the *fabliau* were respectively written.

The second piece referred to above is the Plunder of the *Cathair* of *Mael Milscothach*, or *Mael* "of the honeyed words," written by *Erard Mac Coise*, who died about the year 1023. The poet had a *Cathair*, or residence, at *Clurtha*, now Clara in Westmeath, which was plundered and demolished in his absence by some of the O'Neills, and his furniture, ornaments, and cattle carried off. *Mac Coise* not being in a position to demand redress directly, had recourse to his art. Going to the *Dun* of *Domnal O'Neill* at *Ailech*, near Derry, the king, as was customary, asked him what tales he could recite; the poet names those he knows, all of which the king has heard before save one called the Plunder of *Mael Milscothach's Cathair*, which he desires to hear. *Mac Coise* then describes the attack and destruction of his house, using allegorical names for all the actors in the outrage. He first gives the pedigree of *Mael* "of the honeyed words," from the god *Dagda*. As the hostile party approach the *Cathair* the nymph of poetry ascends to the top, and asks who they are, and what they seek. The spokesman of the enemy gives a number of allegorical names, which when interpreted mean the O'Neills themselves. The nymph asks would they not prefer the jewels of poetic eloquence and eulogy to the torturing lash of satire, for she possessed abundance of both, from the panegyrics of *Mac Lónáin*, the satires of *Mórán*, the eloquence of *Laidech*, the stories of *Leach Liathmhúim*, the proverbs of *Fíthal*, the wisdom of the *Ferceirtnés*, the intellect of the poetess *Etain*, the brilliancy of *Nera*, the clear truths of the princess *Mór Mumhan*. The marauders heed not the question, but burst into the house and plunder it. On going to the cellar they are met by the guardian *Dathghel*, who enumerates the male and female defenders of the place; these are no other than the various household articles personified, such as "Bellows, son of constant Fire-place;" "Blanket, son of Women's Work;" "Broom, daughter of Tidiness," and so on. The result of this clever piece of satire was the restoration of the poet's property, and compensation for his loss.

The subject of law and its literature will be found fully Law treated under the heading BREHON LAW, vol. iv. p. 252.

Among the gods of the Irish pantheon mentioned above is *Diancécht*, that is, *Dia na Cécht*, the god of the powers (of healing). In the *Táin Bó Cuailnge*, a *Fáth-Liag*, or prophet-leech, heals the wounds of *Cúchulainn* after his fight with *Ferdiad*. It is probable, therefore, that in pagan times the *Liag*, leech, belonged to the order which may be conventionally called Druidic, and that charms and incantations formed part of the means of cure, like those of the Gallo-Roman physician *Marcellus Burdigallensis*. The position assigned to the leech by the laws in the Middle Ages was a very high one. He ranked with the smith and the *Cerd*, or artist in gold and silver; and the *Ollamh*, or doctor in leechcraft, ranked with an *Aire Ard*, that is, one of the highest grades of lord, who had ten free-stock tenants and ten base-stock tenants. He had also a distinguished place at assemblies, and at the table of the king. Leechcraft became hereditary in certain families, some of whose names indicate their profession, as O'Lee, that is *O'Liagh*, the descendant of the leech; and O'Hickey, *O'Hiceadha*, the descendant of the healer. The heads of these families kept schools of leechcraft, as the *Breitheams* kept schools of law, many of which were in existence in the

¹ *Fabliaux et contes des Poètes Français des XI &c. Siècles*, publié par Barbazan, Paris, 1808, vol. iv. p. 80.

16th century, for Campion, who wrote in 1571, says of both classes of schools, "They speake Latine like a vulgar language, learned in their common schooles of Leachcraft and Law, whereat they begin children, and hold on sixteene or twentie yeares conning by roate the Aphorismes of Hypocrates, and the Civill Institutions, and a few other parings of those two faculties." Many of the books of these families still exist in the libraries of the Royal Irish Academy, the King's Inns, &c., in Dublin. These books show that the Irish leeches were well acquainted with the works of Hippocrates, Dioscorides, Galen, Avicenna, Rhazes, and most of the medical writers of the Continent of their time. They also contain early translations into Irish of several medical works of repute.

With the exception of the hymn of St Colman *O'Cluasaghe*, published in the Liber Hymnorum of the early Irish Church, some fragments of poems attributed to St Béc Mac Dé, and some others, everything ecclesiastical which could with certainty be referred to an early period is in Latin, and therefore outside the scope of this article. The *Leabhar Breac*, or Speckled Book, now in the library of the Royal Irish Academy, contains chiefly religious writings, which give us the means of estimating what may be called the popular religious literature in the 13th and 14th centuries. It contains homilies on moral, scriptural, doctrinal, and ritualistic subjects, *e.g.*, on the duties of kings and subjects, on charity, almsgiving, the ten commandments, the commandments of the church, the different festivals, prayer, fasting, and abstinence, baptism, the ceremonies of the mass, &c.; an epitome of Bible history from the Creation to the Ascension, which often so closely follows the text of the Scriptures, that we may regard it almost as a translation; the legends of the Finding and Exaltation of the Holy Cross, embodying much of the Gospel of Nicodemus, which was popularized in every country in Europe in the Middle Ages; the acts of several saints, which are found in Early English, French, and German literature; the lives of the three principal Irish saints, Patrick, Brigit, and Columcille, and of some others; the elegies of St Colum Cille, and St Senán, &c. There are also many legendary lives of the saints of the early Irish Church in some of the principal vellum manuscripts. It will thus be seen that the popular religious literature in Ireland did not differ from that of neighbouring countries, and on the whole bears favourable comparison with it.

We have no direct evidence that the Pictish language was ever written, but inductive reasoning is rather against the supposition, for no trace of a poem or legend has survived. The cause of this is not far to seek. The Pictish language, as we have already pointed out, was a Goidelic dialect, which at the period of the principal Dalriadic settlement in the west of Scotland did not perhaps differ from Irish more than Low German or Alemanian does from High German, if even so much. There was just difference enough to make intercourse between the Scots and the Picts at first somewhat difficult. This close relationship of language is no doubt the explanation of the readiness with which Scots and Picts allied against the Britons. In the 5th and 6th centuries, when the Irish kingdom established in Alba began to become an important factor in the affairs of that country, the Irish were a lettered people. The Irish *Fili*, or poet, followed in the track of the Irish missionary, and carried the poems and historic tales of Ireland among a kindred people, having the same eponymous ancestors, and nearly identical mythological traditions. For several centuries after the conversion of the Picts, Alba, as Scotland was then called, was a second home to the Irish *Ceile Dé*, or monk, and the Irish poet and harper. Even in the 12th and 13th centuries the Irish poets and musicians included Scotland in

their circuit, and took refuge, or sought their fortune there. We shall mention one instance as it happens to be instructive in another way, that of *Muiredhach O'Daly*, better known, on account of his long residence in Scotland, as *Muiredhach Albanach*, or *Muireach* the Albanian, or as we should now say, the Scotchman. Did we not know the whole history of this man, who is believed by the Rev. Dr T. M'Lauchlan to be the ancestor of the great race of Mac Vurrichs, bards to MacDonald of Clanranald, we should never have suspected him to have been an Irish *Fili*. It is easy to understand how under these circumstances the literary and cultivated language came to be Irish. But beneath this literary language there was the under-current of the original Pictish, which was gradually modified under the influence of the Irish, in the same way that a literary language always influences the spoken language. Nor should we forget that in this case the action was more potent because it was directly exerted on the people through the preachers, and by the bards reciting their poems and telling their stories. Towards the middle of the 15th century Irish literature began to decline and the Irish language to recede. Irish poets and musicians still continued, however, to include Scotland in their visitations, but the connection between the two countries began to be weakened, and the Scottish dialect accordingly gradually rose into literary importance. Poems and tales began to be written in it; and those originally written in Irish were recast in the local dialect. There can be no doubt, too, that the legends and historical traditions brought over from Ireland, which had been transformed by, or had absorbed into them, the primitive Pictish traditions of the same kind which grew from the same original stem, began to be recast and modified, and a new growth of legends to spring up indigenous to Scotland. In this way a *Gaelic* literature arose, of which some examples are to be found in the Dean of Lismore's Book. Its development was, however, arrested by the Reformation. This would have been only a temporary check, but for the political changes which followed, and which by gradually bringing the most remote part of the Highlands into the current of a wider and more active political life, and by drawing to the capital and within the direct influence of modern European culture the Scottish nobility, gave an additional stimulus to the spread of English, and reduced the Gaelic to a peasants' patois. Under other and more favourable circumstances the translation of the Bible into Gaelic, and the composition of a Gaelic liturgy, together with the change in the whole current of religious ideas, might have given rise to a new type of Celtic literature.

The success which attended some translations made by James MacPherson led him to make a tour in the Highlands, and to gather as many poems and other specimens of Gaelic literature as he could find. It was no doubt during this tour that he matured his idea of using the legends preserved in the popular memory, written down in Scottish Gaelic, and existing in the Irish MSS., which he came across in his travels, as materials out of which to compose the poems which have since become so celebrated under the name of the poems of Ossian. We mean of course the English poems, for in the usual sense of that word no Gaelic originals existed. The so-called originals are a very curious kind of mosaic, constructed evidently with great labour afterwards, in which sentences, or parts of sentences of genuine poems are cemented together in a very inferior word-paste of MacPherson's own. We have pointed out that the personages of the two cycles of romance, the heroic and the Fenian, are never mingled as actors in genuine national poetry or tales. This is, however, done commonly by MacPherson. Thus in *Dar-thula*, which

MacPherson's
Ossian.

is based upon a tale of the heroic age called the Exile of the Sons of *Uisnech*, we have *Deirdriu* (Dar-thula), *Nois* (Nathos), *Ardan*, and *Cathbad* (Cathba) the Druid, actors of the original tale, associated with *Oisín* and *Cormac* who belong to a different time and another phase of Irish legend. In *Temora* we have *Fingal* son of *Cumall* (Fingal), his son *Oisín* (Ossian) and grandson *Oscar*, and *Cormac Mac Airt*, associated with *Cathaeir Mór*, *Nois* (Nathos), *Cúchulaind* (Cuthulin), and the antediluvian *Carill*. Again, in *Fingal*, which has manifestly been written under the influence of the *Táin Bó Cuailnge*, we have *Carill*, *Cúchulaind*, *Cathbad*, *Conlaech* (Conloch) son of *Cúchulaind*, *Ferdiad* son of *Daman* (Ferdia), associated with *Finn* (Fingal), *Oisín* (Ossian), *Oscar*, *Goll Mac Morna* (Gaul, son of Morna), and other heroes of the Ossianic period. This mingling of the heroes of two different cycles of romance would be sufficient to prove, did we possess no other test, that MacPherson had no original. The old Celtic tales are especially characterized on the one hand by the detailed descriptions they give of the personal appearance, dress, and arms of the chief actors in a tale, and of the internal arrangements of the houses, &c.; and on the other by the absence of descriptions of scenery, except when *Tír Tairngire*, the Land of Promise, is in question. The aspects of nature were familiar to those who listened to those tales, what they wanted to realize was the actors and their deeds. MacPherson's poems on the contrary are full of word-pictures of nature, sometimes no doubt bombastic, but generally giving beautiful, and often grandly poetic, descriptions of the most characteristic features of the scenery of the Highlands. But the actors in his epic are like figures seen through a mist, barely sketched in outline, whose dress, ornaments, and arms are so generally and vaguely described as to lose all peculiar and distinctive character. The Poems of Ossian are thoroughly modern, more so even than the current legends of the west of Scotland which retain many things—talking ravens, soothsaying, &c., which savour of old times. An examination of the poems and prose tales of the Irish Ossianic cycle is very instructive in this connection; the older they are the more detailed are the descriptions of the actors and of their dress and arms; the newer the vaguer and more general—the more like MacPherson's heroes do they become. In this respect MacPherson did no more than what he was entitled to do, and what has been done by others who have used similar materials for the construction of poems. The author of the *Nibelungen Lay* fused in the 12th century legends of the Horny Siegfried with those of a different and newer cycle concerning Attila, Dietrich von Bern, Brunhild, &c. So the romances of Arthur and the St Graal, though of a totally different origin have mingled together. So, too, the mediæval German poets took many liberties with the French romances, which served them as materials. What he had no right to do was to call his poem a translation. It is unfortunate for his fame that he should have supported this comparatively trivial error by the grave one of producing his pretended original. Let us add that the publication of a selection of the poems in the manuscript known as the Dean of Lismore's Book by Mr W. F. Skene and the Rev. T. M'Lauchlan, and Mr J. F. Campbell's collection of *Popular Tales of the West Highlands*, have done more to settle the Ossianic controversy than all that had been written by the combatants on both sides.

The number of Welsh manuscripts is considerable, but with the exception of those in the British Museum, the library of Jesus College, Oxford, and that of the university of Cambridge, they are all in private collections. Of these the most important is the Hengwrt collection, consisting of the manuscripts collected by Mr Jones of Gelly

Lyddy, between the years 1590 and 1630, and by the antiquary Mr Robert Vaughan of Hengwrt, who died in 1666. The two collectors arranged that their manuscripts should be united on the death of one of them, the survivor to become the possessor of the whole. According to this arrangement they became the property of Mr Vaughan, and hence got the name of the Hengwrt collection. Some years ago Sir Robert Vaughan bequeathed the collection, comprising, we believe, about four hundred volumes, to Mr W. W. E. Wynne of Peniarth, in whose possession it now is. But although Welsh manuscripts are numerous there are very few of any considerable antiquity, the others being comparatively modern compilations, often the work of ignorant scribes, the contents of which seem for the most part to have been in the first instance taken from the old books just spoken of. Of such old books there are, exclusive of law manuscripts, only five of such antiquity or importance as to deserve special mention here. The first is a copy of the hexametrical paraphrase of the Gospels of Juvenius in the University Library of Cambridge, as old at least as the 9th century. The only Welsh it contains are some glosses and two short poems written in Irish characters; but as the oldest specimens of Welsh known they are invaluable as a standard wherewith to compare the language of other manuscripts. The second is the Black Book of Carmarthen, a small quarto vellum manuscript of 54 leaves, written in Gothic letters by various hands in the reign of Henry II. (1154–1189). This manuscript originally belonged to the Priory of Black Canons at Carmarthen, and was given by the treasurer of the Church of St David to one of the commissioners appointed by Henry VIII. for the suppressed monasteries, Sir John Price. It is now in the Hengwrt collection at Peniarth. The third is the Book of Taliessin, also in the Hengwrt collection, a small quarto manuscript consisting of 38 leaves of vellum written in Gothic letters throughout in one hand, some time in the early part of the 14th century. Its history before it came into the possession of Robert Vaughan, the antiquary, is not known. The fourth is the Book of Aneurin, a small quarto manuscript of 19 leaves of vellum, written probably in the end of the 13th century. It was purchased by the late Sir Thomas Phillips of Middlehill, and may have been formerly in the Hengwrt collection. The fifth is the Red Book of Hergest, so called from Hergest Court, one of the seats of the Vaughans, for whom it was probably compiled. This important manuscript, the chief repository of Welsh literature, is a folio volume of 360 leaves of vellum, written in double columns at different times, from the early part of the 14th to the middle of the 15th century, and is now in the library of Jesus College, Oxford.

The text of a large number of the poems and other compositions contained in Welsh manuscripts has been published in a work in three volumes, called the *Myvyrian Archæology of Wales*. The first volume, containing poems, and the second, chronicles and historical documents of various kinds, were published in 1801; and the third, moral, didactic, legal, and miscellaneous pieces, in 1803. This publication is due to the noble patriotism of three men,—Owen Jones, a furrier in London, and the son of a Welshman, with whom the idea originated while still a young man, and who devoted no inconsiderable portion of his fortune to its realization; Edward Williams, a stonemason, better known by his assumed name of *Iolo Morgannwg*, the chief contributor to the collection; and William Owen, who afterwards assumed the name of Pughe, the author of the principal dictionary of the Welsh. Had the critical judgment and knowledge of the editors equalled their patriotism, the work would be of great value.

Welsh manuscript literature may be classed for our

Classifica-
tion of
Welsh li-
terature.

purpose under the following heads:—(1.) Glossaries and grammars; (2.) The *Bruts*, or annals, genealogies, and histories; (3.) Poems; (4.) *Mabinogion*, and other prose tales; (5.) Laws; (6.) Medicine and science. There are very few Welsh glossaries, because there exist in fact few examples of obsolete or old Welsh. The oldest Welsh laws are attributed to *Howel Dda*, who died in 950, and the oldest codex containing them is believed to have been written in the 12th century. If this codex contained the laws in their original form they would probably require no gloss to explain them, because the language did not change very much in the interval between the framing of the laws and the writing of the manuscripts. But like all Welsh manuscripts, even the oldest copy of the laws gives us an edition in the language of the time. A grammar of the Welsh, said to have been made by *Edeyrn Dafod Aur*, by the order and at the desire of three Welsh princes, in the second half of the 13th century, has been published by the Rev. J. Williams ab Ithel, from a copy made in 1832 from another copy made in 1821 from a manuscript of Edward Williams, or *Iolo Morganwg*. Whatever may be the intrinsic scientific value of the treatise itself, this is a very doubtful source to derive historical value from. Mr Williams has also published in the same volume a work on the rules of Welsh poetry, originally compiled by *Davydd Ddu Athraw* in the 14th century, and subsequently enlarged by *Simwnt Vychan* in the 16th century. We have no evidence as to how much belonged to the former and how much to the latter, but it all appears to belong to the 17th century. Mr Williams has also added a great deal of matter of his own, which is distinguished from the text by being printed in smaller type. His object was to combine in one volume as complete a body of information on the subject as possible. It would be outside the scope of this article to criticise this laborious work.

If we might judge by names alone, the British, between the departure of the Romans and the conversion of the Anglo-Saxons, possessed many historians. Welsh antiquaries give a long list, and some find a place even in the works of English and foreign writers; but with the exception of Gildas and Nennius, the titles only of their writings are known, nor are these above suspicion. Bede quotes Gildas, and so far we have proof that as early as his time there was a belief in the existence of such an author. The works now known as those of Gildas and Nennius are written in Latin, and are properly outside our scope, but they are so inseparably connected with the *Bruts* or Annals, and with the history of romance, that we must say a few words concerning each. Gildas was the son of a British king of *Ailclyd*, the present Dumbarton, and was therefore from that part of Britain referred to in Welsh works as *y Gogledd*. Several dates have been assigned for his birth and death, but we prefer for the former 516, and for the latter 570, and his book *De Excidio Britannie*, if genuine, seems to have been written about 560. According to his legendary lives, he went to Ireland on the invitation of St Brigit, founded monasteries there, and taught at the school of Armagh. His work above named is written in an inflated style, and is a mere sketch of British history under the Romans, and in the period immediately succeeding their withdrawal from the country, and so includes the period of the wars of the Britons with the Picts, Scots, and Saxons; it is full of blunders and anachronisms. Mr Skene suggests, very reasonably, that the well-known letter of the Britons to Aetius, asking for Roman aid, is misplaced, and that if put in its proper place the discrepancy between Gildas's account of the departure of the Romans from Britain and that of Greek and Roman writers will disappear.

Nothing is known of the person called Nennius, to whom

the short History of the Britons known by his name is attributed. In the earliest known manuscript of it, written about the middle of the 10th century, and now in the Vatican Library, it is ascribed to a certain Marc, who is believed to be the Marc who with his nephew, *Moewgal*, better known as Marcellus (little Marc), came to the monastery of St Gall about the middle of the 9th century, having with him many books and a considerable retinue. Bestowing his wealth on his followers, and reserving for himself only the books, he and his nephew remained at St Gall, where the latter became celebrated as the teacher of Notker, Ratpert, and Tutilo. Mr Skene thinks it was originally written in British in Cumbria, or *y Gogledd*, and was afterwards translated into Latin. To this nucleus was added the genealogies of the Saxon kings, down to 738; the above-mentioned Marc appended, probably about 823, the life of St Germanus, and the legends of St Patrick, which were subsequently incorporated with the history. Some South Welshman added to the oldest manuscript of the history in these countries, about 977, a chronicle of events from 444 to 954, in which there are genealogies beginning with *Owain*, son of *Howel Dda* king of South Wales. This chronicle, which is not found in other manuscripts, has been made the basis of two later chronicles brought down to 1286 and 1288 respectively. It is consequently not the work of one author. A *Sai* and *Fili*, named *Gilla Caomhan*, who died 1072, translated it into Irish, and added many things concerning the Irish and the Picts.

The *Historia Britonum* is more valuable for the legendary matter which it contains than for what may be accepted as history, for it gives us, at least as early as the 10th century, the British legends of the colonization of Great Britain and Ireland, the exploits of King Arthur, and the wonderful birth and prophecies of Merlin, which are not found elsewhere before the 12th century. The date of the book is of the greatest importance to the history of mediæval romance, and there can now be no doubt, especially since the publication of the Irish Nennius, that it is earlier than the Norman Conquest, and that the legends themselves are of British origin. The books attributed to Gildas and Nennius contain the germs of the fables which expanded into Geoffrey of Monmouth's History of Britain, which was written in Latin sometime before 1147, the date of the epistle dedicatory to Robert, earl of Gloucester, the son of Henry I. by *Nest*, only daughter of *Rhys ab Tewdwr*, and was a manifestation of the great advance which took place in Welsh literature consequent on the restoration of the Welsh prince just named, and of *Gruffydd ab Cynan*, and of which we shall have more to say hereafter. In the epistle just referred to Geoffrey states that Walter, archdeacon of Oxford, had given him a very ancient book in the British tongue, giving an account of the kings of Britain from Brutus to *Cadwaladr*, and that he had translated it into Latin at the archdeacon's request. But in the Welsh version of Geoffrey's chronicle in the *Myvyrian Archaeology*, the *Brut Geoffrey ap Arthur*, there is this postscript: "I, Walter, archdeacon of Oxford, did turn this book out of Welsh into Latin; and in my old age I turned it a second time out of Latin into Welsh." That Geoffrey drew his materials from British sources, and did not coin any of them, seems to us the legitimate conclusion to be drawn from a careful study of the whole subject. His book is, however, a compilation and not a translation, at all events no book now exists which can be regarded as his original, while all the *Bruts* or chronicles are posterior to Geoffrey's book and based upon it. Of these there are the *Brut Tysilio* and the *Brut Geoffrey ap Arthur*, both of which are also called *Brut y Brenhinoedd*, or Chronicle of the Kings. The copy of the latter in the Red Book is

Geoffrey of
Monmouth.

The *Bruts*.

Gildas.

Nennius.

followed by a chronicle in continuation which, according to an entry in a later hand, was called *Brut Twysogion*, or Chronicle of the Priuces. In some manuscripts there is also added a chronicle of Welsh events interspersed with Saxon ones, which is from this called the *Brut y Saeson*, or Chronicle of the Saxons; in one manuscript this is attributed to Caradoc of Llancarvan. The chronicle of events from 444 to 954, which is contained in the British Museum manuscript of the History of Nennius, and two other chronicles, already mentioned, bringing events down to 1286 and 1288, have been printed together as the *Annales Cambriae*. These later chronicles ought not, as Mr Skene properly remarks, to have been incorporated with the older one, which alone possesses the special value of having been written before the Norman Conquest, and a century and a half before the *Bruts*.

The Triads. Besides the chronicles or *Bruts* there are no historical works properly so called in Welsh, unless we include the Triads, a curious kind of literature peculiar to Wales; for although there are some Irish Triads they are imitations of the Welsh ones, an imitation which fortunately did not extend very far. The Triads are an arrangement of similar subjects, similar events, or things which might be associated in the mind, or be worthy of remembrance, &c., in series of three, e.g., "Three ornaments of a hamlet—a book, a teacher versed in song, and a smith in his smithy;" or "Three punishments for theft in hand—the first is imprisonment, the second is cutting off a limb, the third is hanging." This kind of composition appears to have come into use in the 12th century, the earliest specimen being the Triads of the Horses, which are in the Black Book. The Triads of Arthur and his warriors are perhaps as old as the 13th century. The Red Book contains the Triads of the Island of Britain, which include those last mentioned, an enlarged edition of the Triads of the Horses, and many others. The Triads of *Dyfuwal Moelmuad*, a supposed ancient king of Britain, are perhaps as old as the beginning of the 16th century.

Welsh poetry.

The poetic literature of the Welsh, which is very extensive, may be conveniently divided into—(1.) Poems attributed to poets who lived before the 12th century, and anonymous poems in the Black Book; and (2.) Poems written by or attributed to poets who lived in the 12th and succeeding centuries. The claims of the Welsh to possess an ancient literature rests altogether on the poems of the first category, hence they have been the subject of much discussion. The grounds upon which such discussions have hitherto rested have altered considerably within the last few years. The labours of Zenss and others who have worked at Celtic philology, and the discovery of specimens of Old Welsh in the Cambridge Codex of Juvencus, furnish us with much safer canons of criticism than existed in 1849, when even a learned Welshman, the late Mr Thomas Stephens, who did more than any one else to establish the claims of his country to a real literature, doubted the authenticity of a large number of the poems said to have been written by Taliessin, Aneurin, Merlin, and Llywarch Hên, who are supposed to have lived in the 5th century. Mr W. F. Skene has done a very great service to Welsh literature by the publication of the texts of those poems from the four principal manuscripts now known, the Black Book, the Book of Taliessin, the Book of Aneurin, and the Red Book. In addition to the texts Mr Skene has given translations of the poems specially made for him by the Rev. D. Silvan Evans and the Rev. Robert Williams, so that next to the Welsh Laws, and Stephens's *Literature of the Kymry*, his *Four Ancient Books of Wales* is the most important contribution to Welsh literature yet made.

If we judge by the test of language alone, the poems which we have included in our first category, and which

are nearly all to be found in Mr Skene's book, are not in their present form older than the 11th century. But while the form may be new the substance may be old, as we have already pointed out in the case of many Irish poems. It is probable that many of the poems attributed to Aneurin, and several of the mythological and religious poems, are only popular editions of much older poems, and further that the change effected in some of them may be so small that we have substantially the original poems. Others again have been so deeply modified that they may be regarded as new poems on an old theme.

The following classification of those poems shows their origin, and will help to render the few observations we can offer here more intelligible.

1. Poems referring to events in Romanized Britain, or to the east frontier of Wales.
2. Poems referring to events on the Mercian frontier and in South Cumbria.
3. Poems referring to personages and events connected with the *Gwyddel* or Goidelic occupation of Wales and Cornwall.
4. Poems referring to the *Gwyr y Gogledd*, or Men of the North.
5. Poems relating to or attributed to *Taliessin* of a general character.
6. Proverbial poetry attributed to *Llywarch Hên*.
7. Poems attributed to poets between the 7th and 11th centuries.
8. Anonymous religious poems in the Black Book.
9. Poems referring to personages and events of Welsh history in the 12th and subsequent centuries.

The first class is represented by one poem in the Book of *Taliessin*, The Reconciliation of *Llad* the Less, which would be unintelligible but for a *Mabinogi* to which we shall refer later. The poem has no mark of antiquity about it, and belongs to the 13th century. To the second class belong the Death Song of *Eros*, and other pieces in which that warrior is mentioned, and the Death Song of *Uthyr Pendragon*, all of which are in the Book of *Taliessin*, and in form and substance are not older than the 12th century. The poems of the third class are of considerable importance, but here we shall merely give the names of a few as examples, reserving what we have to say concerning them until we come to the *Mabinogion*. The following are good examples of the class—The Death Song of *Corroi*, The Battle of *Godeu*, and The Chair of *Ceridwen*, from the Book of *Taliessin*; the *Preiddeu Annwn*; *Daronwy*, and the poems relating to *Gwyddyn ap Don*, from the Black Book, the Book of *Taliessin*, and the Red Book. The poems which belong to the fourth class are the most numerous and important. Among them may be mentioned first of all the *Gododin* poems, those relating to *Urien Rheged*, the war between the sons of *Llywarch Hên* and *Mwg Mawr Drefydd*, poems relating to the battle of *Adderyd*, as for instance the *Avallenau*, or Apple Trees, and poems relating to *Cadwaladr* and *Cadwaladr*. We have already explained that *y Gogledd* was that portion of Britain which lay between the Walls of Hadrian and Antoninus, and had been erected into the Roman province of Valentia. As it was a loose term, it may have included all the independent British country north of the Ribble. This country, and especially that part of it forming the ancient diocese of Glasgow, was the cradle of the Welsh language and literature. It was the only part that could have been this. Here the question naturally suggests itself, to what extent was Britain Romanized? That it was not so to the extent usually supposed may be shown in many ways. It is obvious that, if the southern Britons were as thoroughly Romanized as Gaul or Spain, the language of Cornwall should have been a

Classification of reputed older Welsh poems.

Extent to which Britain was Romanized.

Romance dialect, and that of Brittany an allied one. Again, if the Welsh were a remnant of the Romanized Britons driven westward by the conquering Saxons, the Welsh language also should be a Romance dialect, or its vocabulary should contain a large intermixture of words borrowed from the Latin, and especially of words connected with law, trades, &c. But this is not so. The fact is the population of Britain was not Romanized to any extent. In the towns the principal citizens no doubt spoke Latin, as they speak English in Calcutta and other large towns in India. A large British population in part bilingual gathered round the cities and towns, as the Irish did about the Anglo-Norman towns of the Pale, and as the Letts, Esthonians, and Russians do about the German towns of the Russian Baltic provinces. We should also not forget that the legionaries in the 2d and 3d centuries were only Roman in name, being recruited from every part of the empire, and consequently could not contribute to Romanizing the inhabitants among whom they were located. The peasantry continued British, but the nobility, no doubt, learned to speak Latin, but not for home use. When afterwards the Saxons on the east and the Irish on the west of what is now Wales displaced the ruling families, the Romanized part of the independent British population, hemmed in between the two hostile peoples, and with an ever-encroaching Saxon frontier on one side, gradually merged into the Celtic-speaking peasantry, and lost the use of the Latin tongue. This was not a state of things favourable for the development of a literature. In the north especially, between the Walls of Hadrian and Antoninus, in the province of Valentia, which never had Roman towns, only camps occupied by legionaries, who for the most part probably spoke no Latin, the whole population must have remained essentially British after the withdrawal of Roman power. Here if anywhere the first germs of a British literature should show themselves, and accordingly tradition makes *Taliessin*, *Aneurin*, *Llywarch Hên*, and *Myrddin* or *Merlin*, to whom most of the supposed ancient Welsh poems are attributed, natives of this region. Here also the actors in the events referred to in the poems lived, and the places where those events are supposed to have taken place are to be found. The greater part of this region, too, enjoyed substantial independence down to the end of the 9th century, with the exception of the interval from 655, when they were subjected to the kingdom of Northumbria by Oswy, after the defeat of *Cadwallawn* and *Penda*, to the battle of *Dunneichen* in 686, when *Egfrid*, king of Northumbria, was defeated. From the 7th to the 9th century Cumbria, including under that name all the British territory from the Ribble to the Clyde, was the principal theatre of British and Saxon conflict. The rise of the dynasty of *Mailcun*, who according to Welsh tradition was a descendant of *Cunedda*, one of the *Gwyddel* or *Goidelic* Picts of the district called *Gnotodin*, brought Wales into close connection with the Cumbrian kingdom, and prepared both North and South Wales for the reception of the northern traditions and the rise of a true Welsh literature.

Whether the poets of Cumbria really wrote any of the poems which in a modified form have come down to us or not, there can be no doubt that a number of lays attributed to them lived in popular tradition, and that under the sudden burst of glory which the deeds of *Cadwallawn* called forth, and which ended in the disastrous defeat of 655, a British literature began to spring up, and was nourished by the hopes of a future resurrection under his son *Cadwalludyr*, whose death was disbelieved in for so long a time. These floating lays and traditions gradually gathered into North Wales, according as the nobility and bards sought refuge there from the advancing conquests of the Saxon kings in the north. The heroes of Cumbria

became Welshmen, and the sites of the battles they fought were identified with places of similar name in Wales and England. When *Howel Dda* became king of all Wales, the legends of the north passed into South Wales, and like the legends of *Oisín* in Scotland, became so thoroughly identified with their new home, that they seem to have first originated there.

Of all the poems attributed to the four ancient Welsh bards, the one which has most claim to be considered genuine, and the only one we can specially allude to here, is that known as *y Gododin*. As published by Mr Skene from the Book of *Aneurin*, it consists of 94 stanzas, and is both obscure and fragmentary. The latter character Mr Skene explains, and we think successfully, by supposing that it consists in reality of two distinct poems, referring to two events separated by a long interval of time. The first event is the battle of *Caertraeth*, the *Bellum Mithorun* of Adamnan, fought between the Britons and Scots under *Aedan*, king of Dalriada, and the pagan Saxons and their British subjects in *Devyr* and *Bryneich* or *Deira* and *Bernicia*, and the half-pagan Picts of *Gnotodin*, a district corresponding to the northern part of the Lothians along the Firth of Forth. *Caertraeth* was the adjoining district on the Forth where the great Roman wall terminates at *Carriiden*, the Fort of *Eidinn*. If this view be correct, and it is the best that has yet been proposed, the *Mynyddau* of the poem was *Aedan Mae Gabran*, and the battle the one fought in 596, of which Columcille prophesied that *Aedan* would be unfortunate but victorious,—the misfortune being doubtless the loss of his four sons in the battle, one of whom was named *Artur* (*Art*). The second and later portion of the poem, Mr Skene thinks, refers to the battle of *Stratheairinn*, now *Strathcarron*, in which *Domnal Brec*, king of the Dalriadic Scots of *Alba*, was slain, 642. In the brevity of the narrative, the careless boldness of the actors as they present themselves, the condensed energy of the action, and the fierce exultation of the slaughter, together with the recurring elegiac note, this poem (or poems if it be the work of two authors) has some of the highest epic qualities. The ideas and manners are in harmony with the age and country to which it is referred. The poems called the *Gorchans*, which are also found in the Book of *Aneurin*, and refer to the personages and events of the *Gododin*, possess many of the characteristics of that poem, and are probably the work of the same time, if not of the same poet.

Still more celebrated than *Aneurin*, the reputed author of *y Gododin*, was *Taliessin*, a name which has been interpreted as "Splendid Forehead," and has consequently been the subject of a good deal of mysticism. The number of poems in the Book of *Taliessin* supposed to have been written by him is considerable; in language they are not older than the 12th century, though many of them may be what we have called in other cases popular editions of older poems. Several belong to the fourth class which we have been just considering; the poems which we would include in a special fifth class are those which have been made the subject of bardic speculation in consequence of their generality and vagueness, such as the *Fold of the Bards*, *Hostile Confederacy*, *Song to the Wind*, *Mead Song*, *Songs to Great and Little Worlds*, *Elegy of the Thousand Sons*, *Pleasant things of Taliessin*. Many of these poems possess considerable merit, and even as the work of the 12th and 13th centuries might bear comparison with similar compositions in other European literatures of the period.

The poems of the sixth class attributed to *Llywarch Hên* are in the Red Book, and are the work of some Tupper of the 14th century, too disinterestedly proud of his work to put his own name to it. They are curious

and interesting examples of a sort of proverbial philosophy in which each proverb or wise saw is accompanied by a reference to some natural feature, such as "Bright the tops of the broom," which serves as a kind of mnemonic catchword. This catchword is sometimes the same in every verse, as in the poem *Ŵyry mnyd*, mountain snow.

Welsh tradition has preserved few poems of the period between the end of the 6th century and the end of the 11th, a period of 500 years, nor for the matter of that even the names of poets, a circumstance which is intelligible enough if we consider that Welsh literature really began with the 11th century, but inexplicable according to the ordinary views of Welshmen. In the Black Book are five poems attributed to three poets who lived in the early part of the barren interval,—*Meigant*, whose name also occurs in Irish literature; *Elaeth*, to whom are attributed two out of the five poems, which are of a religious character; and *Cuhelyn*, a bard of the 9th century. The two poems attributed to the last are of very great importance, because in them occurs the earliest mention of the goddess *Ceridwen*, who plays so conspicuous a part in the modern bardic system of Neo-Druidism. The anonymous religious poems of the Black Book, apart from the language, may belong to any time from the 6th to the 12th centuries; they probably belong in great part to the 11th and 12th centuries, and were most likely the work of the monks in whose monastery the Black Book was compiled. The ninth and last division of the early Welsh poems are those which covertly allude to passing events in Wales, and can therefore be no older than those events. Two of them refer to *Powys* in Norman times, the Satire of *Cynan Garwyn*, son of *Brochwael*, in the Book of *Taliessin*, and the elegy on *Cyndylan* in the Red Book. The others are the poems which Mr Skene groups together under the head "Poems which mention Henry or the son of Henry;" the most important of them are those attributed to *Myrdin* or Merlin, such as the Dialogue between *Myrdin* and his sister *Gwendydd*, a Fugitive Poem of *Myrdin* in his Grave, containing a number of predictions, and the Songs of the Little Pigs, each stanza of which begins with "*Oian a par-chellan*," "Listen, O Little Pig." The structure of the last poem being like that of the poem called the *Avellenau*, each stanza of which commences with that word "Sweet Apple-tree," both are classed together, and in the *Myvyrian Archæology* are attributed to Merlin. The *Avellenau* is, however, found in the Black Book, and is every way an older poem; but it is needless to add that none of the poems of Merlin are genuine, and that with the exception perhaps of the Apple-tree poem, they all refer to times later than the 12th century, and to the present Wales.

Before discussing the second division of Welsh poetic literature, or poems written by or attributed to poets who lived in Wales in the 12th and succeeding centuries, we must say a few words on the Welsh bards. The organization of the classes of learned men in Wales was far less developed than in Ireland. According to the laws each king or prince had a household bard, who appears to have performed the functions of the Irish *Sai* and *Fili*, and also that of harper. His position was honourable, and on investiture he was presented by the king with a harp, and by the queen with a gold ring. Beside the *Bardd Teulu*, or household bard just spoken of, a *Pencerdd*, chief of song, is mentioned in the laws, who in North Wales was an officer of the household, but in South Wales was not,—his position there being apparently that of a privileged personage entitled to make a circuit and so spend his time where he pleased. The chief of song was also called a chaired bard, because he was one of the fourteen entitled to a chair at court. The installation of a bard to a chair appears to have been attended with some ceremony, for the judge of

the king's court was entitled as a perquisite of his office to the bugle-horn, the gold ring, and the cushion which was under the bard on the occasion. The *Pencerdd* represented the Irish *Ollamh Fili*, and like him appears to have kept a school of poetry, for he was entitled to receive 24 pence from each minstrel who completed his course of instruction, to their services "as a man placed in authority over them," and to the *Gobyr* or *Amobyr* of their daughters, that is to the fee payable to the lord on the marriage of a maiden. Among his emoluments was a fee of 24 pence from every maiden on her marriage. In the court his seat was on the side of the judge of the court, and he lodged with the *Edling*, that is the heir-apparent of the king or prince, corresponding to the Irish *Tánaiste*. A villain or serf could not become a bard, nor a smith without the permission of his lord; nor could a bard practise his art after he had taken holy orders. Should a serf or a stranger happen to become a bard he became personally a free *Cymro* or Welshman, but his children were not free, though the time in which his descendants might rise to the privileges of a free *Cymro* was shortened. A minor bard was forbidden to solicit a gift without the permission of the *Pencerdd*, but the latter might ask a gift though all others should be forbidden to do so. The duty of the chief of song was to commence the singing or recitation of poetry by singing two songs on entering the hall, one concerning God and the other about kings; the household bard then repeated the third song below the entrance of the hall. This is nearly all that the laws contain about bards. There is not a word about the *Ovydd*, or the Druid-bard, nor about the sky-blue dress of the former, the emblem of peace and truth, nor of the white robe of the Druid, nor of the green robe of the *Ovydd*, the colour of nature, nor of the robe of the *Awenydd* or bardic student striped with the three colours, nor of the *Gorsedd* or assembly of bards. If any of these things existed in the 12th century, the most brilliant period of Welsh poetry, we should expect to find them in the Welsh laws. But so far from any relics of the ancient Druidic organization having survived at that period, it is probable that even the organization above given from the laws was in part at least the work of *Gruffydd ab Cynan*. They are, in fact, the inventions of later times when Wales had lost its political liberty. We have the first stage of the invention in the Triads, and it seems to have been completed by that extraordinary man Edward Williams, whom we have already mentioned as one of the editors and the principal contributor of the *Myvyrian Archæology*, who pretended to be the head of the bardic order of South Wales, and accordingly assumed the bardic title of *Iolo Morgannwg* from his native county of Glamorgan. He is probably the source whence the Rev. Edward Davies derived the chief part of the material for his marvellous system of Neo-Druidic philosophy. According to the supporters of this system, the religion of the Druids, a medley of sun-worship and Jewish Noachian traditions, the emblems of which were the bull, the horse, and fire, survived the introduction of Christianity, and continued to be believed by the bards, and its rites practised in secret by them. The principal source whence evidence was derived in support of this assumption was the early poems which we have been discussing. Davies gave what he called translations of some of those poems, in which the simplest and plainest phrases are made to express mysterious and abstruse doctrines. In the religious poems which contain such expressions as "Christ the Son," "Merciful Trinity," Mr Davies omits the latter, or treats them as mere phrases introduced to deceive the uninitiated, and make them believe the pagan bards were Christians. Among the doctrines attributed to the Neo-Druids was that of metempsychosis. The chief source from whence evidence was derived in

Poets from the 7th to the 11th century.

Religious poems in Black Book

Poems attributed to *Myrdin*.

The Welsh bards.

support of this assumption outside a pretended work called *Barddas*, or treatise on the whole system of the bards, which *Iolo Morganwg* possessed, was the Romance called *Hanes Taliessin*, or history of *Taliessin*, which though partly prose, and therefore coming under the head of the prose romances, of which we shall speak later, may be more conveniently referred to here. A fragment of the Welsh text of this history was given in the *Myvyrian Archæology*; the whole tale was afterwards published by Dr Owen Pughe; and Lady Charlotte Guest published it again in the third volume of her *Mabinogion* from two fragments, one dated about 1758, and the other belonging to *Iolo Morganwg*. The romance of the *Hanes Taliessin* in its existing form belongs to the beginning of the 17th century. Of the thirteen poems contained in Lady Charlotte Guest's book, only two are found in the Book of *Taliessin*, the Ode to the Wind and the Mead Song. It is evident that a number of poems attributed to *Taliessin* were floating about in popular tradition, and were strung together in the 16th century into a romance. Although of these so taken up only the two just mentioned find a place in the special manuscript of *Taliessin's* poems in the 14th century, we are not therefore entitled to assume that the other poems did not therefore exist at that period. It is singular that the compiler of the *Hanes Taliessin* did not include such poems as the *Canu y Meirch*, or the Song of the Horses, which would find its place after the account of the contest of *Elphin* against the 24 horses of *Mailcun*, the Ale Song, which is the counterpart of the Mead Song, the Chair of *Taliessin*, and the Chair of the Sovereign (*Kadeir Teyrn*). In all these there is no mythology, nor indeed anything indicative of a secret. But when the Elegy of the Thousand Sons, a religious poem on the saints before and after Christ, which is in the Book of *Taliessin*, is believed to contain the doctrine of metempsychosis, any doctrine whatever may be drawn from the Welsh poetry. But while the whole of the Neo-Druidic speculations must be looked upon as fables, it does not follow that there are no mythological allusions in Welsh poems as old as from the 12th to the 14th century. We have already alluded to the occurrence of the name of the goddess *Ceridwen* in two poems in the Black Book attributed to *Cuhelyn*, a bard of the 9th century. The following poems in the Book of *Taliessin* also contain traces of mythology:—Song concerning the Sons of *Llyr* ab *Brochwel*, the Chair of *Ceridwen*, the Spoils of *Anwn*, *Daronwg*, and the *Angar Cyfindawd*. But as the mythology of the poems is intimately connected with that of the prose tales we shall reserve our observations on the subject until we are considering the *Mabinogion*.

Whether the poems we have been hitherto considering were really first written after the 10th century, or, as seems much more probable, were composed at an earlier period and transmitted by popular tradition, their language undergoing the same changes as the spoken language, they must be considered from a merely literary point of view as the products of the period from the 11th to the 13th century inclusive. But apart from those poems there is another and a perfectly legitimate Welsh literature which may be said to have commenced with the restoration of the old royal families of North and South Wales. *Rhys ab Tewdwr*, the reputed legitimate heir to the throne of South Wales, returned from Brittany in 1077 bringing with him no doubt the Armorican legends of the Round Table; and *Gruffydd ab Cynan* came in 1080 from Ireland, where he was born and had been educated, and where he must have become familiar with its poetry and music. Indeed, we know on the authority of Welsh writers that *Gruffydd* reorganized the bards and improved the music, and in other ways gave a great and beneficial impulse to Welsh literature. Among the changes which he effected in the organization of the

bards may have been the institution of bardic *Gorsedd*s or meetings, of which the modern *Eisteddfod* is an imitation. In Ireland the poets did not, so far as we know, hold separate meetings of this kind, but they took a prominent part in the great periodic gatherings called *Donchs* or fairs held for a threefold purpose,—for promulgating laws, for public games, and as a market. At these gatherings poems were sung, stories narrated, and prizes awarded.

One of the earliest poets whose productions we can be certain of is *Meilyr*, bard of *Trahacarn*, whom *Gruffydd ab Cynan* defeated at the battle of Carno, and afterwards of the conqueror *Gruffydd* himself. His best piece is the Death-bed of the Bard, a semi-religious poem, which is distinguished by the structure of the verse, poetic feeling, and religious thought. *Meilyr* was the head of a family of bards; his son was *Gwalchmai*, one of the best Welsh poets; and the latter had two sons, *Einion* and *Meilyr*, some of whose poetry has reached us. *Gwalchmai* was a true poet, and not a mere professional bard. In his *Gorhoffedd Gwalchmai*, *Gwalchmai's Delights*, there is an appreciation of the charms of nature, the murmuring of brooks, and the songs of birds not unworthy of one of the modern Lake poets. His *Arwyrain i Owain* is an ode of considerable beauty, and full of vigour in praise of *Owain Gwynedd*, king of North Wales, on account of his victory of *Tal y Moelvre*, part of which has been translated by Gray under the name of "The Triumphs of Owen." This translation, though not very literal, preserves the terseness and boldness of action of the original. *Kynddelw*, who lived in the second half of the 12th century, was a contemporary of *Gwalchmai*, and wrote on a great number of subjects including religious ones; indeed, some of his eulogies have a kind of religious prelude. He had command of words and much skill in versification, but he is pleonastic and fond of complicated metres and of ending his lines with the same syllable. There is a certain obscurity about some of his poems which has given him an importance among the disciples of the Neo-Druidic or bardic philosophy. Among the other poets of the second half of the 12th century may be mentioned *Owain Kyveilug* and *Howel ab Owain Gwynedd*. The first-named was prince of *Powys*, and was distinguished also as a soldier. The *Hirlas*, or Drinking Horn, is a rather long poem marked alike by originality and poetic merit. The prince represents himself as carousing in his hall after a fight; bidding his cup-bearer fill his great drinking-horn, he orders him to present it in turn to each of the assembled warriors. As the horn passes from hand to hand he eulogizes each in a verse beginning *Diwallaw di venestr*, "Fill, cup-bearer." Having thus praised the deeds of two warriors, *Tudyr* and *Morwiddig*, he turns round to challenge them, but suddenly recollecting that they had fallen in the fray, and listening as it were to their dying groans, he bursts into a broken lamentation for their loss. The second was also a prince; he was the eldest of the many sons of *Owain Gwynedd*, and ruled for two years after his father until he fell in a battle between himself and his step-brother David. He was a young man of conspicuous merit, and one of the most charming poets of Wales,—his poems being especially free from the conceits, trivial common-places, and complicated metres of the professional bards, while full of gay humour, a love of nature, and a delicate appreciation of woman. Some of his love songs especially are charming. There are two other poets, who, though they lived into the 13th century, belonged perhaps more to the 12th, namely, *Llywarch ab Llewelyn* and *Gwynvardd Brycheiniog*. Mr Stephens attributes the Songs of the Figs to the former, and believes that the poet covertly alludes to the events which occurred in the reign of *Llewelyn ab Iorwerth*, grandson of *Owain Gwynedd*; but as this poem occurs in the Black Book it can hardly

Poets of the 12th century.

Mythological poems.

Influence of *Rhys ab Tewdwr* and *Gruffydd ab Cynan* on Welsh poetry.

be the work of *Llywarch*. The poems which are distinctly referred to him are marked by much power of delineation and poetic feeling, of which his address to *Llewelyn ab Iorwerth* affords a good instance. The Welsh poets, as we have said, went circuit like their Irish brethren, staying in each place according as hospitality was extended to them. When departing, a bard was expected to leave a sample of his versification behind him. In this way many manuscripts came to be written, as we find them, in different hands. The Irish manuscript known as the Book of Fermoy is just such a book kept in the house of David Roche of Fermoy in the 15th century. *Llywarch* has left us one of those departing eulogies addressed to *Rhys Gryg*, prince of South Wales, which affords a favourable specimen of his style. *Gwynwardd Brycheiniog's* poem on St David, in which he enumerates all the churches dedicated to the saint, is a typical example of a kind of topographical poem abounding in Irish. There is an early anonymous example of this kind of poem in the Black Book, the *Englynionn y Bedeu*, The Verses of the Graves, which is the exact counterpart of the Irish Lay of the *Leachts*, and some other poems of the same kind.

Poets of
the 13th
century.

The following are a few of the poets of the 13th century whose poems are still extant. *Darydd Benfras* was the author of a poem in praise of *Llewelyn ab Iorwerth*; his works, though not so verbose or trite as bardic poems of this class usually are, do not rise much above the bardic level, and are full of alliteration. *Elidyr Sais* was, as his name implies, of Saxon origin, and wrote chiefly religious poetry. *Einiarn ab Gwgawn* is the author of an extant address to *Llewelyn ab Iorwerth* of considerable merit. *Phylip Brydydd*, or Philip the poet, was household bard to *Rhys Gryg* (*Rhys* the hoarse), lord of South Wales; one of his pieces, An Apology to *Rhys Gryg*, is a striking example of the fulsome epithets a household bard was expected to bestow upon his patron, and of the privileged domesticity in which the bards lived, which as in Ireland must have been fatal to genius. *Prydydd Bychan*, the Little Poet, was a South Wales bard, whose extant works consist of short poems all addressed to his own princes. The chief feature of his *Englynionn* is the use of a kind of assonance in which in some cases the final vowels agreed alternately in each quatrain, and in others each line ended in a different vowel,—in both cases with alliteration and consonance of final consonants, or full rhyme. *Llygad Gwr* is known by an ode in five parts to *Llewelyn ab Gruffydd* written about the year 1270, which is a good type of the conventional flattery of a family bard. *Hewel Voel*, who was of Irish extraction, possessed some poetical merit; his remonstrance to *Llewelyn* against the imprisonment of his brother *Owain* is a pleasing variety upon the conventional eulogy. It has many lines commencing with the same word, e.g., *gwr*, man. The poems of *Bleddyn Vardd*, or *Bleddyn* the Bard, which have come down to us are all short eulogies and elegies. One of the latter on *Llewelyn ab Gruffydd* is a good example of the elaborate and artificial nature of the Welsh versification. There are seven quatrains, the first, second, and fourth of which all end in *-af*. With the exception of the first and last stanza the first three lines of each stanza begin with *gwr*, man, or a compound of it, "manly." The second, third, and fourth lines of the first stanza also begin in the same way; the fourth line is a kind of refrain, which in the first two stanzas begins like the other lines with *gwr* or a compound of it; in the third and last it begins with *yn*, and in the fourth, fifth, and sixth with *hyd*. The best of all the poets of the century was *Gruffydd ab yr Ynad Coch*, whose elegy, notwithstanding its alliteration and conventional use of the same initial word, or of words having the same fore-sound, has the ring of true poetry. His religious poems, too,

possess considerable merit. But of all the religious poems in early Welsh we have seen, that which best deserves the name is one written by *Madawc ab Gwallter*.

The death of *Llewelyn* and the subjugation of all Wales, and especially the social and other internal changes which took place in the Principality, necessarily checked literary efforts. A general revival took place, however, in the time of *Owain Glyndwr* and the Wars of the Roses, with which the Welsh had much to do. In the meantime a considerable improvement had taken place in the æsthetic feeling of the people. The bardic system, which had helped to raise the Celtic people in their tribal stage above other barbarous peoples, but which at a later period had fettered their intellectual and political development, was, at least so far as regards exclusive privileges, at an end: inter-tribal wars had ceased, and great improvements in the houses, churches, dress, and food of the people had taken place. Love supplanted war as the theme of song, and much attention was paid to language and versification. Nature, too, was made a theme of poetry by several poets. We have already had occasion to notice some examples of this love of nature; but at the period we are now considering, one cannot help being struck with the power of observation of natural phenomena, and the keen sense of objective natural beauty, which many Welsh poets exhibit; nor is there wanting the higher poetic feeling of subjective beauty. These high qualities are, it is true, often marred by artificial systems of versification. Among the poets who flourished in the 14th century, the following may be mentioned. *Gwilym Ddu* is the author of two odes to the unfortunate Sir *Gruffydd Llwyd*, one of which, the Odes of the Months, written in 1322, was composed while the subject of it was in prison. Forty-three out of sixty-three begin with the word *neud*; it is moreover strongly alliterated, and many of the lines end in *-ed*. He is also the author of an elegy on the poet *Trahaearn*, son of *Gronwy*, a contemporary poet. This poem, which is a panegyric on Welsh poets past and present, is skilfully constructed. A considerable number of writers of love *Englynionn*s flourished at this time, among whom may be specially mentioned *Iorwerth Vychan*, *Casnodyn*, who is believed to be the same as the foregoing *Trahaearn*, and *Gronwy ab Davydd*, who was probably the father of the latter. But the representative poets of this period are *Rhys Goch ab Rhicert* and *Davydd ab Gwilym*. The verses of the former to a Maiden's Hair, though strongly alliterated and rhymed, are smooth and less intricate and conventional than most poems of the period, and possess a good deal of the character of the love romances of the time, in Southern Europe, with which he undoubtedly was acquainted. Both *Rhys Goch* and *Davydd ab Gwilym*, the Cambrian Petrarch, as he has been called, were great lovers of nature, and no modern poets sing more sweetly of the woodland, wild-flowers, the voice of birds, and other charms of the country. It is amidst such scenes they place their lovers, who are real swains and maids, and not the mock ones of the pastoral poetry of the 18th century. Two hundred and sixty-two poems, chiefly pastoral of *Davydd ab Gwilym* are said to exist, some of which, as for instance his exquisite Ode to Summer, would be worthy of any literature.

The most distinguished poet of the 15th century was *Lewis Glyn Cothi*, more than one hundred and fifty of whose poems are known. The period of the civil wars in the 17th century had its poets, the best known of whom, *Huw Morus*, was on the Royalist side. Since then a new literature has grown up which, however, lies outside the scope of this article.

We have already alluded to the probability of the tales in verse, whether historical or romantic, being earlier than those in prose. Most of the heroes of the earlier poems,

Prose tales

whatever may be their real age, are also the subjects of prose tales. In the poems, as a rule, if there be any definite picture of the actors, they appear as men, and there is very little neeromancy surrounding them; the prose tales, on the other hand, are full of marvels and magial transformations. In the older prose tales there is a certain unity in the personages and events; gradually two or more streams of romance mingle, as in MacPherson's Ossian. The Welsh prose tales all belong to South Wales; the poems, on the other hand, belong to a large extent to North Wales. The prose tales which still exist are few in number, and are evidently only a small part of those which were once current. The reason of the small number of prose tales preserved, as compared with the very large number of poems, is doubtless to be explained by the fact that the poets were a privileged class, who formed part of the households of the lords; while the prose tales were chiefly told by the strolling minstrels, against whom, and not against the bards properly so called, so many severe enactments were made. The privileged bards despised the tales of the story-teller, and hence, unfortunately for the history of romance and of comparative mythology, so few have been preserved.

Classifica-
tion of
prose tales.

In the Red Book there are eleven prose tales, which have been published by Lady Charlotte Guest, together with the *Manes Taliessin*, of which we have spoken above, under the name of *Mabinogion*, though that name is applied in the Red Book to four only. We may classify them thus according to their origin. I. Roman-British—(1) The Contention of *Lludd* and *Llelwy*; (2) The Dream of *Maxen Wledic*. II. Irish Romances—(3) The Tale of *Pwyll*, Prince of *Dyfed*; (4) *Branwen*, daughter of *Llyr*; (5) *Manawyddan*, the son of *Llyr*; (6) *Math*, son of *Mathonwy*. III. Arthurian Romances—(7) The Lady of the Fountain; (8) *Peredur*, son of *Evrawc*; (9) *Geraint*, son of *Erbin*. IV. Mixed Romances—(10) The Story of *Kilhwch and Olwen*; (11) The Dream of *Rhymabwy*. To the category of mixed romances may also be added, as a third kind, the story of the St Graal contained in a Hengwrt manuscript.

Roman-
British
tales.

The first story relates to *Lludd*, son of *Beli* the great, son of *Manogan*, who became king after his father's death, while his brother *Llelwy* becomes king of France, and shows his brother how to get rid of the three plagues which devastated Britain:—first a strange race, the *Coranians*, whose knowledge was so great that they heard everything, no matter how low soever it might be spoken; second, a shriek which came into every house on May eve, caused by the fighting of two dragons; and third, a great giant, who carried off all the provisions in the king's palace every day. The second relates how *Maxen* or *Maximus*, emperor of Rome, has a dream while hunting, in which he imagines that he visits Britain, and sees a beautiful damsel, *Helen*, whom he ultimately succeeds in finding and marrying. The personages of this tale are mentioned in the earliest form of the *Brut Gruffydd ab Arthur*, but the account is different. Both tales seem to be British, and to be traceable to Roman times.

Goidelic
romances
or *Mabi-
nogion*.

We have called the second group Irish romances, not only because the action in some of them is placed occasionally in Ireland, and some of the actors are distinctly stated to have been Irishmen, but because they are unmistakably relics of the period of the occupation of the coast of Wales by the *Gwyddel* or Irish. The group of four romances form a eyele of legends, and are the only ones called *Mabinogion* in the manuscript from which they have been taken. In the first tale the principal characters are *Pwyll*, prince of *Dyfed*, and *Arawn*, king of *Annwn* or *Annwryn*; in the second *Bran* and *Manawyddan* the sons, and *Branwen* the daughter, of *Llyr*, and *Matholwch*, king of Ireland; in the third *Manawyddan*, son of *Llyr*, and *Pryderi*, son

of *Pwyll*; and in the fourth, *Math*, son of *Mathonwy*, king of *Arvon* and *Mona*, *Gwydyon ap Don* and *Arianrod* his sister, and *Llew Llaw Gyffes* and *Dylan eil Ton*, the sons of *Arianrod*. These personages are mentioned in several of the poems attributed to *Taliessin*, in whose reputed works curiously enough the relics of the ancient mythology are chiefly found. Among these poems we may mention the following, some of which are in the Book of *Taliessin*, while others are not:—*Kadeir Kerrituen*, or the Chair of *Ceridwen*; the Spoils of *Annwn*; the *Kat Godeu*, the Battle of *Godeu*; *Murwnat eil Ton*, the Death Song of *Dylan*, son of the wave; *Daronwy*; *Augar Cyfindawd*; the story of *Llyr ab Brochwel Powys*;—in other words, all the so-called mythological poems. In these tales and poems we have undoubtedly the relics of the ancient Irish mythology of the *Tuatha Dé Danann*, sometimes mixed with later Arthurian myths. The *Cacr Sidi* is the *Síd* of Irish mythology, the residence of the gods of the *Aes Síde*. The seven other *Caers* or residences mentioned in the poem on the Spoils of *Annwn* are the various *Síde* of the immortals. *Llyr* is the Irish sea-god *Lér*, and was called *Llyr Llediaith*, or the half-tongued, implying that he spoke a language only partially intelligible to the people of the country. *Bran*, the son of *Llyr*, is the Irish *Bran Mac Allait*, *Allat* being one of the names of *Lér*. This *Bran* is probably the same as *Brian*, son of *Tuirem*, though according to the Irish genealogies, *Brian* would be the nephew of *Lér*. *Manawyddan ap Llyr* is clearly the *Manandan* or *Manannan Mac Lir* of Irish mythology. In one derivation of his name, if correct, we have a most important link in these romances. According to this etymology, *Manannan* comes from *Man*, lord, and *Annan*, of the foamy sea, *Lér*, his father's name, meaning also the sea. In *Annan* we would have the *Annwn* of the poems, and of the story of *Pwyll*, and commonly identified with hell, but really corresponding to the *Tír Tairngire* or Elysium of the Irish. *Rhiannon*, the wife of *Pwyll*, who possessed marvellous birds which held warriors spell-bound for eighty years by their singing, comes from *Annwn*, and her son *Pryderi* gives her, on the death of *Pwyll*, as a wife to *Manawyddan*. With *Annwn* or *Annwryn* we naturally connect the Irish *Ana*, the mother of the gods, or *Mór Rígu*, and wife of the *Dagda*. She was the mother of *Aed*, the Welsh *Aed Mawr*, and was probably the same as *Ceridwen*. In a previous part of this article we have made the *Dagda* the same as *Delbáith Dana* or *Tuirem*, the father of *Lér*; if we are right in our conjecture, *Ana* would be the mother of *Lér*, the sea, as well as of *Aed*, fire. *Rhiannon*, daughter of *Heveydd Hen*, and wife of *Pwyll*, and afterwards of *Manawyddan*, is perhaps also to be connected with *Ana* and *Annwn*. Again, the *Cacr Sidi* above mentioned, where neither disease nor old age affects any one, is called the prison of *Gweir* in one of the poems. This *Gweir*, we have no doubt, represents *Gaiar*, son of *Manandan Mac Lir*, the Atropos who cut the thread of life of Irish mythology. In one legend *Gaiar* is made the son of *Uisle* and of *Deirdriu*, celebrated in the story of the sons of *Uisnech*, and the foster son of *Manandan*, who aids him in banishing *Conchobar Mac Nessa* to Alba on account of his killing the sons of *Uisnech*, and becoming king of Ulster in his place. Afterwards, *Gaiar* relinquishes the kingship by the advice of *Manandan*, who takes him to *Enchain Abhlach*, or *Emain* of the Apple-trees, where he dies. *Gaiar's* sister *Aeb-gréine*, the Sunlike, married *Rinn*, son of *Echaid Inil* of *Tír Tairngire*, or the Land of Promise. This *Rinn* takes part in the contests between the swineherds of *Ochull Ochne* and *Badb*, chiefs of the rival *Síde*, who after a series of metamorphoses become the *Finnuenduch*, or bull of Connaught, and the *Donn Cualngiu*, the celebrated bull of the *Táin Bó Cuailnge*. *Math*, son of *Mathonwy*, may be connected with *Mat*, the great Druid of the *Tuatha Dé*.

Danann. The necromancer *Mathene* or *Louán*, the companion of *Art*, of whom we shall have something to say presently, may be a relic of the older mythology. Nor should we forget to mention in connection with this name that the mother of Queen *Medb* or *Mab* was *Mata Muirisc*. The *Llew Llaw Gyffes* of the tale of *Math*, son of *Mathonwy*, is *Lug Láam Fada*, king of the *Tuatha Dé Danann*, whose mother was *Ethlenn* or *Cethlenn*, daughter of *Balor* of the Evil Eye, a Fomorian chief. This *Lug* was known by several names, among which was that of the *Sab Ildanach*, or Skilful Pillar, because he knew or supported all arts, a name which connects him with *Illanach* or *Ildanach* (Skilful), son of *Manandan*. *Lug*, according to Irish legends, was the first who introduced fighting on horseback into Ireland, and who established funeral games. *Gwydyon*, son of *Don*, who fills so important a part in the early Welsh poems and tales, was the brother of *Arianrod*, the mother of *Llew Llaw Gyffes* and of *Dylan*, Son of the Wave, and the grandson of *Daronwy*, the son of *Brynach* or *Urnach Wyddel* by *Corth*, daughter of *Brychan*, by which another line of legend, originating also in Ireland, is brought into connection. *Gwydyon* is an enchanter of wonderful power, his master being *Math*. He produces a woman from blossoms, and the forms of horses from springing plants. The tale of *Math*, son of *Mathonwy*, is full of such transformations as those of the swine-herds in the preface to the *Táin Bó Cuailnge*. There are also similar transformations in the poem of the *Kat Godeu*, or *Battle of Godeu*. The Milky Way is called *Caer Gwydyon*; the constellation Cassiopeia is *Llys Don*, the court of *Don*; and the Corona Borealis is *Caer Arianrod*, the residence of *Arianrod*, daughter of *Don*, and mother of *Llew*. Thus *Arianrod* is the same as *Ethlenn*. There are several *Dons* or *Donns* in Irish romance:—the chief of the Munster fairies, or people of the *Side*, was *Donn Fírinne* of *Cnoc Fírinne*, now Knockfierna, in the west of the county of Limerick; *Donn Dumhach*, or *Donn* of the sandbank at the mouth of the *Eidhneach* near Ennistymon, in the county of Clare, and *Donn Chnuic na n-Oss*, now Knockanoss, in the county of Cork, were also chiefs of *Side*. These examples show that *Don*, the father of *Gwydyon*, may be connected with the *Aes Side*. *Manandan Mac Lir* had a son who was *Ech-Don Mór*, or the great *Ech-Don*, who is probably the *Donn* mentioned in the Fenian *Agallamh na Senorach*, or Dialogue of the Sages, as having been slain by a certain *Derg Dianscothach* in a war between *Ilbhreach* of the *Síd* of *Eas Ruadh* and *Lér* of *Síd Fínnachuidh*. It may be remarked here that whenever the *Aes Side* are brought into the Fenian romances there is generally some confusion. Thus in the romance just mentioned *Lér* is represented as at war with *Ilbhreach*, who in the genealogies is made the son of *Manandan*. Before leaving those curious tales, it will be better to discuss one of the mixed romances, The Story of *Kilhwch* and *Olwen*. By mixed romance we mean one in which two distinct streams of legends have mingled. The one just mentioned belonged originally to the same class of legends as the four *Mabinogion* we have been discussing, but it got mixed up with the Arthurian romance. *Kilhwch* asks for wife *Olwen*, the daughter of *Yspaddaden Penkaur*, who imposes upon him a number of tasks before he would give him his daughter, the final one being to fetch the comb and scissors which were between the ears of the *Twrch Trwyth*. All these he effects through the aid of his cousin Arthur. Among the personages mentioned are—*Anaethon*, son of *Don*, who is represented as a great husbandman, and *Govannon*, son of *Don*, a smith. Among the actors are *Gwyther*, the son of *Greidawl*, who is betrothed to *Creiddylad*, daughter of *Lludd Llaw Ereint*, that is Cordelia, daughter of Lear. *Gwen Ap Nudd*, however, carries off *Creiddylad*, but Arthur makes peace between them, the condition being that the maiden should

be restored to her father's house, and *Gwen* and *Gwyther* should fight for the yellow-haired maiden on the first of May each year. This very curious tale is altogether based on Irish mythology. *Govannon* is *Goibniu*, the Irish Vulcan, the brother of *Diancécht* or *Dia na-cécht*, the god of the powers (of healing). *Creiddylad* is the Irish *Creide of Tir Tairngire*. The *Twrch Trwyth* is the Irish *Torc Triath*, the King Boar. Indeed the story puts him in Ireland, and says that he cannot be hunted without *Garselit* the *Gwyddelian*, the chief huntsman of Ireland. This king boar belonged to *Brigit*, the poetess daughter of the *Dagda*, the Minerva of the Irish. *Nudd*, the father of *Gwen*, is apparently *Neit* (battle), the god of war, and *Kilhwch* himself seems to represent *Coin Ceallach*—son of *Delbaith*, son of *Neit*, the god of war—who received the name *Eludan* (art, skill) in consequence of the skill he displayed in preparing ropes for capturing *Masan*, king of Britain.

By an Arthurian romance we mean a tale in which Arthur is a chief hero, and the scene of which is laid in Wales or South England. The legends of Arthur in this sense belong chiefly to South Wales, and must have originated there in great part, though they were afterwards much modified by new elements introduced from Armorica by *Rhys ab Iewddur* and his followers at the end of the 11th century. At this period South Wales was more civilized than North Wales, because less mountainous and more fertile, and also because it had considerable intercourse with France. These very circumstances led to its conquest by the Normans earlier than North Wales, which maintained its independence nearly a century longer. Before the advent of the Normans in South Wales, stone-built castles and churches existed, but they erected much stronger and more splendid castles, and the clergy whom they introduced built fine churches and great abbeys. The Norman castles and walled towns and trained men at arms, always ready for war, must have afforded more protection to commerce and agriculture than it could enjoy under the Welsh tribal system. The wants of the new nobility, too, were greater, their courts were more splendid, their dresses and arms more costly than those of Welsh princes; and corresponding splendour was introduced into the ceremonies of the church. The Norman baron was not prouder, but he was graver and more courtly than the Welsh lord. All these things acted on the popular stories and gradually transformed them, as manners improved, into elegant romances of chivalry. The abundant materials of romance which existed in Wales were the property, so to say, of the strolling minstrels and peasantry, and were despised by the lettered bard with whose poems the popular tales competed. Carried into Armorica, they became, as it were, ennobled, and assumed a more polished and courtly form; and when brought back by *Rhys ab Iewddur*, almost entirely displaced the conventional poems of the bards, which were chiefly eulogies of the living, and elegies of their dead patrons. This is the reason why South Wales produced so few poems from the 12th to the 15th century. These romances were soon translated, or rather new ones constructed upon the same themes, by the Norman Jongleurs, who soon spread them among the Norman nobility everywhere. The heroes of *y Gogledd* were well adapted to serve as actors in the courtly romances. They appear in the poems which we have discussed above as so many lay figures upon which to put the rich dresses and armour of the Normans, and who might be put into a fine castle anywhere without incongruity. The necromancy seems to have been largely borrowed from the Irish legends, a great many of which, of the same character as the *Mabinogion*, must have still existed in the 12th and 13th centuries.

The position assigned to Arthur in romance is due to the accident. No one of the name occupied so prominent a position in the Arthurian romance.

position in the north as to give him of right the place occupied by Arthur in those productions. Some tale or ballad, in which a hero called *Artur* was the chief actor, might have had perchance the necessary elements for popular success; and around this as a nucleus gathered the legends of other *Arturs*. One of the sons of *Aedan Mac Gabran*, killed at the battle of *Cattraeth*, was named *Artur*; and there were doubtless many others of the name, both Scots and Britons. The name *Art* has a place in Irish romance also. Thus *Art*, "the lone man," son of *Conn* of the Hundred Battles, was beloved on account of his great fame by *Becuma* of the fair skin, wife of *Labrad* of the quick-hand-at-sword, and probably the same as *Etain*, a goddess already so often mentioned, and who had been unfaithful with *Gaiar*, son of *Manndan Mac Lir*. *Becuma*, driven out of *Tir Tairngire* or Elysium on account of her offense, is sent adrift in a boat, and lands on the Hill of Howth in Ireland, where, under the name of *Delbh Caemh*, daughter of *Morgan*, she presents herself to *Conn* and marries him. She next insists on the banishment of *Art* from Tara. Evil, however, comes on the country on account of *Conn's* marriage, and the Druids announce that it could only be averted by sprinkling the blood of the son of an undefiled couple on the door posts. *Conn* sails away in search of such a youth, finds him in *Tir Tairngire*, Elysium, and brings him to Ireland. Then we have a scene of exactly the same character as that told of *Gortigern*, but the boy is ultimately saved from immolation by the appearance of his mother, who tells them they must banish *Becuma*. The latter then plays a game of chess with *Art* the son of *Conn*, and he wins, and imposes upon her the obligation of getting the champion's wand which was in the hand of *Curoi Mac Daire* when making the conquest of *Eriu*, and of the whole world. She visits the *Side*, and at length finds it, and brings it to *Art*. They play again, and this time *Becuma* wins, and sends him in search of *Delbh Caemh*, daughter of *Morgan*, i.e., herself, whom he would find in an island in the middle of the sea. He sails away, and arrives at a beautiful island full of apple-trees, flowers, birds, and spotted horses; in which too there were joyous ever-blooming women, and *Crede*, the ever beautiful. Again *Art* was named *Oenfhir*, "the lone man," because his brother *Conulla*, "the beautiful," being invited by a *Ben Side* to rule over *Magh Mell*, "the plain of honey in the Land of Promise," went thither and left him without a brother. *Art* is also credited with having anticipated Christian belief; and consequently it is supposed that neither he nor his son *Cormac* was buried in the pagan cemetery on the River Boyne.

Growth
of the
Arthurian
fable.

It should be remembered that this *Art* lived either at the beginning of the Seotic invasions of Roman Britain, or immediately before that period, for his son *Cormac*, according to Irish legends, was expelled from Ireland, and, going over the sea, obtained the sovereignty of Alba, and his fame must have been carried into Wales, where he must have been the subject of many legends. These legends were the nucleus around which gathered all the floating traditions which came down from the north into North Wales, and thence into South Wales. Some obscure Arthur of the north, perchance *Aedan's* son, was clothed in the legendary glory of *Art*, and was made a *Guledig* or generalissimo, and paramount king of Britain. From South Wales these legends passed into Cornwall and Armorica, where it is probable the Round Table was invented or borrowed in the same way that at a later period the legend of the St Graal, which there is reason to believe originally came from Provence, was carried by the Jongleurs into Brittany, and thence into Wales. If the preceding view be correct, the Arthurian legends attained considerable development in Wales before the Round Table was

developed, and were carried by itinerant story-tellers and musicians among the Normans before Geoffrey of Monmouth wrote his history. That book gave a value to the popular tales which they otherwise could never have attained, and afforded a key by which to correct them. To the Norman clerics the romances owe their polish, and to a large extent their chivalry. But the germs of mediæval chivalry, and even of knight-errantry were already in the original legends, associated, no doubt, with much barbarism.

Besides the *Bruts*, poems, *Mabinogion*, genealogies, and some miscellaneous pieces including a few legendary lives of saints and the grammatical works alluded to in a preceding part, the only other early works in the Welsh language which have been printed, are two medicine books, and a music book. The two medicine books belonged to a family of leeches of *Mydvai* in Carmarthen, descended from *Rhiwallon*, family leech to *Rhys Gryg* or *Rhys* the Hoarse, prince of South Wales, in the 13th century. The oldest of the two books is in the Red Book, and may possibly have been copied from the Book of *Rhiwallon* himself, or of his sons; the second is the Book of *Howel Veddlyg*, or Howel the Leech, a descendant of *Einion*, son of *Rhiwallon*, and was written probably towards the end of the 17th century. Both books are mere dispensatories, and contain very little which would enable us to judge of the theoretical knowledge of disease possessed by the Welsh leeches, and cannot represent the real state of leechcraft in Wales in the 16th and 17th centuries. In Wales the practice of leechcraft was, as in Ireland, hereditary in certain families, who held land by the tenure of medical service. The rank and privileges of the family leech to the king are given in the Welsh laws; and in Wales he was obliged, as in Ireland, to take a guarantee from the kindred of his patient equal to the sum which should be paid for the homicide of a man of his rank, in case he might happen to die from his treatment, otherwise he should answer for his death. The music book, published in the *Myvyrian Archæology*, which is believed to contain some of the ancient music of Wales, and a peculiar system of musical notation, contains merely the music of the lute or some stringed instrument, perhaps the Welsh *Crwth* or *Crowd*, with the notation in common use for such instruments in every part of Europe, and there is no evidence that it contains any of the ancient music of Wales.

Other
Welsh
literature

Medicine

Music.

The literature of the Cornish dialect of the British, which was once the spoken language of the centre and south of England, is very limited indeed. There is first the *Paseon Agan Arluth*, The Passion of our Lord, consisting of 259 stanzas, each of which is a quatrain of four double lines, in rhyme, or eight single heptasyllabic lines with alternate rhymes, the final vowel and consonant in the rhymes being almost always the same in each stanza. This important monument of the Cornish language has been printed with a translation by Mr Whitley Stokes. Secondly, there is the *Ordinalia*, a MS. of which is in the Bodleian Library, Oxford. It forms a dramatic trilogy, consisting of three miracle plays—the Beginning of the World, the Passion, and the Resurrection of our Lord. The latter piece is divided into the Resurrection and the Ascension, with a curious interlude of the putting of Pilate to death. These dramas are founded on the Gospels, the Acts of the Apostles, the apocryphal Gospel of Nicodemus or Acts of Pilate, and several legends which were current all over Europe in the Middle Ages. They are probably translations or adaptations of French miracle plays of the end of the 14th century. The metre is syllabic, with few exceptions, each line having seven syllables, like the lines of the poem of the Passion. A great many of these lines are arranged in stanzas of eight or of four lines, with alternate rhymes, as in the poem just

Cornish
LITERATURE.

mentioned; others in stanzas of six, in which the third rhymes with the sixth, and the others together or in pairs. Occasionally there are eight-lined stanzas, in which the first, second, and third lines, and the fifth, sixth, and seventh lines form triplets rhyming together or separately, and the fourth and eighth lines rhyming together. In lyric and declamatory passages, the lines are occasionally only tetrasyllabic. There are many other varieties of metre, but those here described make up more than three-fourths of the whole. The late Mr Edwin Norris published the *Ordinalia* with a translation under the title of the "Ancient Cornish Drama." The third relic of the Cornish language is a miracle play founded upon the life of St *Meriasek*, son of a duke of Brittauy, and called in Breton *St Meriader*. This piece, which was written in 1504, was found a few years ago by Mr Whitley Stokes among the Hengwrt manuscripts at Peniarth. The language is newer than that of the *Ordinalia*, the admixture of English being also greater; the metre employed is, however, much the same. The fourth work is also a miracle play, The Creation of the World, with Noah's Flood, written in 1611 by one William Jordan. It is written in a more corrupt language than those above mentioned, is full of English words, and imitates, in some instances almost copying, passages in the *Ordinalia*. The remaining literature consists of two versions of the Lord's Prayer, the Commandments, and the Creed, and two indifferent versions of the first chapter of Genesis, a few songs, a short tale, and a few proverbs, and lastly a Cornish Glossary, explanatory of Latin words. The oldest copies of the poem on the Passion is a vellum manuscript in the British Museum of the 15th century; the age of the principal manuscript of the dramatic trilogy is about the same. The Glossary is the most ancient monument of the Cornish language, for the manuscript which contains it belongs probably to the end of the 12th or beginning of the 13th century; and it was copied into this from a more ancient MS. The miracle plays, as we learn from Carew's *Survey of Cornwall*, printed in 1602, were played down to the beginning of the 17th century, in earthen amphitheatres in the open fields as in France and Germany, which in the 18th century, when Borlase wrote, were popularly known as "Rounds."

ARMORIC
OR BRETON
LITERA-
TURE.

Armoric like Welsh is a living language, but no monument of the old form of the language exists, and the relics of Middle-Breton literature consist of two miracle plays, a prayer-book or "Hours," a dictionary, and the chartularies of two monasteries. Of this small list only one of the plays and the dictionary are known to exist in early manuscript originals or copies. The play, which is founded on the life of St Nonna or Nonita, is in a paper manuscript, which has been purchased by the National Library at Paris, and is believed by Zeuss to belong to the 14th century. This piece which, with the chartularies of Rhedon and Landevin, was the principal source whence Zeuss drew the materials for the Armoric part of the *Grammatica Celtica*, was published together with a translation in 1837, under the title of *Buhez Santez Nonn*. The second play, the *Burzud braz Jezuz*, the Great Mystery or Miracle of Jesus, is also referred to the 14th century, but no manuscript of it is known to exist. M. Hersart de la Villemarqué has reprinted it from copies, probably unique, of two editions printed in Paris in the years 1530 and 1622. It consists of two parts—the Passion and the Resurrection, and is treated somewhat differently from the corresponding parts of the Cornish trilogy. It possesses some literary merit, which the elegant translation of the editor does ample justice to. Only two copies of the "Hours," printed apparently in 1524, are known. From these Mr Whitley Stokes has recently reprinted it, adding extracts from a missal printed in 1526,

and a catechism printed in 1576. One of the most valuable of the Middle-Breton documents is the Breton-French and Latin Dictionary of Jean Lagadeuc or Lagadec, curé of Ploegonen, a manuscript of which, extending to the middle of the letter P, dated 1464, is in the National Library of Paris. Under the title of *Le Catholicon* it has been printed several times, the earliest edition being that of 1499.

Miracle-plays died out in France and England in the 16th century, but in Cornwall, as we have seen, they continued to be played down to the beginning of the 17th century, and in Brittany almost down to our own time. The Great Mystery of Jesus, modernized and otherwise altered, was in great repute in the 18th century. One of the widest known and most popular mysteries which have come down to modern times is that of St Tryphine and King Arthur, which M. Luzel has published. The language is more modern than in the two plays above mentioned, and is largely mixed with French expressions, hence we did not include it among Middle-Breton documents. The Breton miracle-plays, as well as the Cornish ones, are free to a great extent from the disgusting realism, coarse expressions, and indecent buffoneries of the English and French plays of the 15th century.

Although modern Breton literature, like modern Welsh literature, is outside the scope of this article, we should except from this category popular poems and tales, for, though modern in form, they contain materials for comparative mythology and linguistic studies, and exhibit the whole intellectual life, belief, and customs of the people, and the impressions which the events of their history have left on the popular mind. Of such collections the most important is M. de la Villemarqué's *Barzaz Breiz*, the fruit of many years' labour in every part of Lower Brittany. This collection consists of *gwers*, or short heroic, historical, or mythological ballads; *sons*, or love and festive songs; and religious poems. The language is, of course, modern, but is full of archaisms, showing very well how old poetic material becomes modified in the current of popular tradition. The Breton text is accompanied by an elegant translation into French, an introduction and notes, and in the sixth edition all the pieces have the original airs noted. Mr Tom Taylor published in 1865 a translation of the *Barzaz Breiz*. M. M. F. Luzel, already well known as the author of a volume of excellent Breton poetry (*Bepred Breizad*, Morlaix, 1865), and by his edition of *Sainte Tryphine et le roi Arthur*, published in 1868 a volume of *gwers* or popular ballads collected in a part of the ancient diocese of Tréguier, under the name of *Gwerzion Breiz-tzel*. Similar collections have been made in other parts of Brittany, especially by MM. Penguern, G. Milin, Goulven-Denis, &c., which have not, so far as we know, been yet published. M. Luzel has also published some popular tales in the Tréguier dialect, and Colonel A. Troude and G. Milin an interesting collection of seven in the Léon dialect.

In concluding what we have had to say on the literature of the respective dialects, it may be well to add a few words on a subject which belongs to all alike, upon which M. de la Villemarqué has given a short essay by way of introduction to his edition of *Le Grand Mystère de Jesus*, and upon which M. Luzel has also some remarks in his *Sainte Tryphine et le roi Arthur*, namely, the theatre of the Celts. M. de la Villemarqué assumes that there is no evidence of a drama among the Goidelic branch of the Celts, but he thinks that it existed among the British branch, at least in an embryonic state, and refers to the Welsh poems in dialogue as evidence. Mr Stephens had already¹ drawn attention to these poetic dialogues,

¹ *Literature of the Kymry*, p. 82.

e.g., those between *Arthur* and *Gwenhwyfar*, *Gwalchmai* and *Trystan*, *Taliessin* and *Myrddin* (*Myrddin* or *Merlin*), &c., and given it as his opinion that written dialogue seems to indicate the existence of drama of some sort, and that dialogues such as those referred to are inexplicable on any other hypothesis. If this argument were admissible, we cannot see how the existence of the dramatic form should be denied to the Irish, inasmuch as dialogue is very frequent in Irish poems and tales. Indeed, the "Fight of *Ferdiad* and *Cúchulaind*," and other episodes of the *Táin Bó Cuailnge*, the *Briáthar chath ban Ulad*, or "Wordy War of the Women of Ulster," the *Siabur charpat Conculaind*, or "Phantom Chariot of *Cúchulaind*," possess as much of the character of incipient drama as any poetic or prose dialogues in Welsh literature. The truth is, however, neither the Welsh nor the Irish had the drama in the proper sense of the word, for the sufficient reason that though, like other Aryan peoples, they may have possessed the germ, it could not be developed among a people who had no civic life. The miracle-plays of the Cornish and Bretons are of foreign and ecclesiastical origin, and merely prove that there existed a closer contact between their churches and the great body of the church in Europe than between the latter and the Irish and Welsh churches. No Welsh miracle-play is known, if there ever was one; nevertheless, it is possible that the words *hud* and *hedrith*, which are explained "illusion," "phantasm," may have really referred to some exhibition of the kind, though the explanation of those words given in the *Iolo MSS.*, upon the authority of a certain *Ieuan Vawr ap y Diwliths*, who, according to Mr Edward Williams (*Iolo Morgannwg*), wrote his treatise on Welsh metres about the year 1180, looks very suspicious. M. de la Villemarqué also alludes to a rustic fête, known as *le jeu de printemps et de la jeunesse*, in which three characters, two young men and one maiden, acted, while the spectators formed the chorus, and repeated the dialogued chants of the principal actors while dancing. Although this fête seems to be a survival of pagan times, and to possess to some extent the elements of an incipient drama, yet in the absence of written monuments or ancient evidence, no argument as to the existence of a native drama among the Celts can be legitimately drawn from it.

Influence
of Celtic
literature
on modern
literature.

Celtic literature, although it has no great masterpiece of its own to point to, has exercised a considerable amount of influence on the creations of modern European literature. This influence was exerted by several distinct currents of legends. The first is that of the legends of the *Aes Síde* and those of Queen *Meld* or *Mab* and the heroic period; of these the existing Irish legends, and the modified form of them in the Welsh *Mabinogion*, give us one type. In Britain this first current, modified and mixed with foreign and especially Teutonic elements, has gone on altering, growing, and decaying until the traces of its origin are almost unrecognizable. It is from this source that much of our fairy mythology is derived, and that Chaucer and Spenser obtained materials. To it also may be traced the legends which formed the groundwork of Shakespeare's immediate sources for *King Lear* and *Midsummer Night's Dream*. The legends of the second stream were in reality but modifications of those of the first—all secondary streams of legend must be necessarily but branches of the primitive stream. These legends were translated into Latin at an early period, and thus, while they spread far and wide, and passed into every language of Europe, we are better able to follow the current up to its first sources. These legends are the Irish *Immram*s or Wanderings and the *Visa* or Visions which we described above. The idea of a land without winter, of never-ending day, in which the flowers of spring and summer should coexist with the fruits of autumn, and in which bodily ills and old age should be

unknown, is common to all lands and to all times. The belief in perpetual youth and especially of abundance of fruit at all times was spread over all Western Europe, and found expression in the popular legends of *Schlauer-affenlande*, *Pays de Cocaigne*, &c. The Irish idea of this kingdom of the dead, an idea common to all the branches of the Celtic race, and to the Teutonic races also, is given us in the descriptions of *Tír Tairngire*, The Land of Promise; *Magh Mell*, The Plain of Honey; and the Country of the *Side*. Thither went several of the heroes of romance—*Cúchulaind*, *Fionn*, *Conn*, and his son *Art*.

In some legends the land of the *Aes Síde* was reached through caves, as in Virgil's Cave of the Sibyl; in others, and more usually, by water,—it being conceived in such cases as an island. In the legends of *Conn* and *Art* this island lay to the eastward, that being the direction in which all the expeditions of the Irish went, the direction in which lay the wealth of the Roman towns of Britain and the metals for bronze of Cornwall. In early Christian times asceticism carried many to the headlands and islands along the west and south-west coast, and the Land of Promise followed the setting sun. A comparison between the Irish pagan and Christian legends of *Tír Tairngire*, the *terra re-promissionis* of the Latin mediæval writers, and those of the Teutonic *Glasberg*, or heaven, shows very clearly the common origin of the two streams. The individual features of the Celtic and Teutonic notions of the kingdom of the dead are the same, though their combinations may differ according to age and other circumstances. The great sea and the island of cats in St Brendan's voyage—the island being also met with in other *Immram*s—are connected with the sacred animal of *Freyja* or *Holda*; the island of black faced dwarfs of the Irish legends reminds us of the dwarfs dwelling in *Glasberg*. Like *Holda's* soul-kingdom, *Tír Tairngire* was an island hidden in a cloud-mantle, enjoying never-ending day and perpetual fogless summer, full of fine mansions surrounded by grassy, flower-bedecked lawns, whose flowers never wither, abounding in apple trees, bearing at the same time flowers and fruit—a land rich in milk, ale, and pork, whose air was ever filled with sweet music, and whose inhabitants enjoying perpetual youth were of spotless innocence, free from blemish, disease, or death. Of all the qualities of *Tír Tairngire* abundance of apples, the only important fruit known to the northern nations, seems to have been the one which conveyed the highest notion of enjoyment. Hence the soul-kingdom was called by the Welsh the island of apples, *Ynys yr Avallon*, and sometimes *Ynysvitrin* or *Ynysgutrinn*, Glass Island, a name which identifies it with the Teutonic *Glasberg*. When these names passed into other languages untranslated, so that their meaning became obscured or forgotten, the kingdom of the dead was localized at Glastonbury, the Anglo-Saxon *Glastinga burh*. There, according to legend, Arthur lies buried, but another popular tradition has it that he was carried away to the island of *Avallon* by his sister the fairy *Morgana*, the *Morgue la Fée* of French romance. This *Morgana* is the *Becuna*, "the fair skinned" daughter of *Morgan*, in search of whom *Art*, "the lone man," visits *Tír Tairngire*, as already mentioned. When *Art* reaches the Land of Promise, the lady he finds is *Crede*, "the ever beautiful." In the romance of *Ogier le Danois*, when *Ogier*, who *Morgue la Fée* determines shall be her lover, arrives at the palace of *Avallon*, he finds there besides *Morgana*, her brother King Arthur, and her brother *Auberon*, the Oberon of fairy romance, and *Mallabron*, a sprite of the sea. A curious legend in the vellum manuscript called the Book of Llanore connects *Brendan* with *Crede*. According to this legend a certain tribe king named *Doburchu*, whose wife's name was *Crede*, was transformed through the curse of *St Brendan* into an

otter. Another link in the chain which connects all these legends with Celtic mythology is the introduction of *Brendan* into the curious legend of the irruption of Loch Neagh, beneath which lived in her sun-house *Líban*, probably the same as *Becuma*, and therefore as *Morgana*, whose lapdog was transformed into an otter when she herself became a salmon. In the Christian *Immram*s or Wanderings the pagan soul-kingdom was simply changed into a place where souls were to await the final resurrection. It is probable, however, that a tradition of real wanderings among the rocky and inaccessible islands along the western coasts of Ireland and Scotland, and on the ocean itself, served as a nucleus around which gathered and fused together the pagan and Christian notions of the kingdom of the dead. The islands of birds, and the whale serving as an island (in the Latin St Brendan *Iasconius*, i.e., Irish *iasc-inis*, fish-island), support this view.

The *Físa*, or prophetic Visions, are merely a different type from the *Immram*s or Wanderings of the same fundamental legends; although perfectly pagan in their origin the better known ones belong to Christian times when the Celtic Soul-Kingdom, and the Christian story of the Day of Judgment, and the Elysium and Tartarus of the Romans, as depicted by Virgil in the sixth book of the *Æneid*, which became known to the Irish as early at least as the 6th century, were fused together. The visions when translated into Latin passed into European languages. The original Irish of some of them is not now known; perhaps some of them were first written in Latin; their thoroughly Irish character, however, and the existence in Irish only of one of the most perfect of them, the Vision of *Adamnán*, lead to the opposite conclusion. The Wandering of St Brendan, the Purgatory of St Patrick, and the Vision of Tundale represent three distinct types of the second stream of legends. The first is the way of getting at the soul-kingdom by water, the second by a cave, and the third by a *fis* or vision, which in pagan times would have formed part of the *Filidecht* of the poet. These three legends, which are to be found in every European language in the Middle Ages, constitute three out of the five main sources of the plot of Dante's great poem.¹ The effect of St Brendan's Voyage upon geographical discovery does not come within our scope, and we shall therefore only add that his island, which was simply the Celtic soul-kingdom, is to be found on maps of the 17th century, and was the subject of an article in a treaty between Spain and Portugal in the 18th.

The third current we have already touched upon. It was formed by the fusion of the legends of *Art*, son of *Conn*, the necromancy of the *Aes Síde*, and the legendary history of the struggles of the Britons and Saxons in the North of England and the South of Scotland, which latter legends supplied heroes, a toponomy, and events. To this stream flowed afterwards, as we have pointed out, the Armorican tributary stream of the Round Table, and the Provençal stream of the St Graal. The effects of this stream of legend, which in its early course belongs to South Wales, on the literatures of Europe is too well known to require discussion here further than to point to its threefold action:—(1) much of the romantic literature of Europe may be traced back directly or indirectly to those legends; (2) they helped as the vehicle of that element we call chivalry, which the church infused into them, to fashion and mould the rude soldiers of feudal times into Christian knights; and (3) they expanded the imagination, and incited the minds of men to inquiry beyond the conventional notions of things, and thus materially assisted in creating modern society.

BIBLIOGRAPHY.—In the following list we have included only the more important works bearing more or less directly upon the subjects treated of in the foregoing article. We have been consequently obliged to exclude many valuable works on the history of Celtic peoples, and especially the numerous and interesting books on Celtic antiquities. Although the Neo-Druidic heresy may be considered to be now fully exploded, we have, nevertheless, deemed it necessary to include a few of the principal works of the upholders of that singular delusion, because of the historic interest which they possess.

CELTIC LANGUAGES, ETHNOLOGY, &c., IN GENERAL.—Zeuss, J. G.: *Grammatica Celtica*, 2 vols., Lipsia, 1853; second and greatly improved edition, Berlin, 1871, ed. by Prof. H. Ebel, embodying all the emendations of Celtic scholars to the time of its publication. Glliek, C. W.: *Die bei Catus Julius Caesar vorkommenden Keltischen Namen*, München, 1857. Stark, Dr Franz: *Keltische Forschungen*, Keltische Personennamen nachgewiesen in den Ortsbenennungen des Codex Traditionum Ecclesie Ravennatensis aus dem VII.-X. Jahrhundert, Wien, 1863. Flechia, Prof.: *Di alcune forme do' nomi locali dell' Italia Superiore*, Torino, 1871. Roget, Baron de Belloguet: *Ethnogenie Gauloise*, Paris, 1858-1861. Diefenbach, Lorenz: *Origines Europeæ, Die Alten Völker Europas*, Frankfurt, 1861; Dr Diefenbach was the first who systematically included the Celtic languages in comparisons with the Germanic languages in his *Vergleichendes Wörterbuch der Germanischen Sprachen*, 2 vols., Frankfurt, 1851. Beiträge zur vergleichenden Sprachforschung auf dem Gebiete der Arischen, Keltischen, und Slawischen Sprachen, herausgegeben von A. Kuha und A. Schleichner, vols. 1-8. This periodical contains the most important contributions made to Celtic philology since the publication of the first edition of Zeuss's *Grammatica Celtica*, such as those of Ebel, Stokes, Schleichner, Cuno, Becker, Aufrecht, Lottner, Pictet, &c. Prof. Ebel's valuable contributions, "Celtische Studien," have, with the exception of those on the verb, been translated into English ("Celtic Studies from the German of Dr Hermann Ebel," &c., by William K. Sullivan, London & Edinburgh, 1863). The Beiträge has been fused with the *Zeitschrift für vergleichende Sprachforschung*, herausgegeben von Dr Adalbert Kuhn. The volume for 1876 contains a remarkable article on the Perfect tense in Irish by Professor Ernest Windisch, who has also done good service by contributing comparisons from the Celtic languages, especially Irish, to the 4th edition of Curtius's *Grundzüge der Griechischen Etymologie* (Leipzig, 1873), and to Professor Fick's work on Greek Proper Names. The *Revue Celtique*, commenced in 1870 by Prof. H. Gaidoz, is the only periodical in Europe exclusively devoted to the scientific study of Celtic, and contains papers by most of the scholars of Europe who devote themselves to the subject—Ad. Pictet, Dr Stokes, Mr J. Rhys, M. M. Perrot, d'Arbols de Jubainville, Le Men, Sauvé, Luzel, &c.

CELTIC EPIGRAPHY.—*Gaulish Inscriptions.*—Professor J. Becker's paper, "Die Inschriftlichen Ueberreste der Keltischen Sprache," published in the 3d and 4th volumes of the Beiträge zur vergleichenden Sprachforschung (1863-1865), is an exhaustive summary of what was known about Gaulish Inscriptions up to that time; see also papers in the Beiträge (by Pictet and Stokes) and in the *Revue Celtique*. *Ogam Inscriptions.*—The Proceedings of the Royal Irish Academy contain the papers of Bishop Graves, Dr Samuel Ferguson, the late Mr R. B. Brash, who are those who have occupied themselves with the subject in Ireland. Dr Ferguson has also contributed a paper on the subject to the journal of the Royal Historical and Archaeological Society of Ireland. The *Archæologia Cambriciensis* may be consulted on the Welsh inscriptions, and in connection with them we may specially mention the name of Mr J. Rhys.

Irusn—Fec-Similes of MSS., published by the Royal Irish Academy.—*Leabhar na h-Uíbhri*: a collection of pieces of prose and verse in the Irish language, compiled and transcribed about 1100 A.D., Dublin, 1870. *Leabhar Breac*, the Speckled Book, otherwise styled *Leabhar Mór*, *Dúna Doighre*, the Great Book of *Dún Doighre*: a collection of pieces in Irish and Latin compiled from ancient sources about the close of the 14th century, Dublin, 1872-1876. Book of Leinster, a MS. of the first half of the 12th century, and the richest repository of poems and tales in the Irish language, now in the library of Trinity College, Dublin.

Language, &c.—O'Donovan's Grammar of the Irish language; Dublin, 1845. O'Reilly's Irish English Dictionary, with a supplement by Dr O'Donovan, Dublin, 1864. Stokes, Dr Whitley: *Irish Glosses*; a mediæval tract on Latin declensions with examples explained in Irish, together with the *Lorica* of Gildas and the Middle Irish Glosses thereon, from the *Leabhar Breac*. Three Irish Glossaries:—Cormac's, O'Davoren's, and a Glossary to the Calendar of *Oingus*, London, 1862; Cormac's Glossary, translated and annotated by O'Donovan, Calcutta, 1863. Goldelica, or notes on the Gaelic manuscripts preserved at Turin, Milan, Bern, Leyden, the Monastery of St Paul in Carinthia, and Cambridge, with eight hymns from the Liber Hymnorum, and the old Irish notes in the Book of Armagh, Calcutta, 1866; also a revised edition. Remarks on the Celtic additions to Curtius's Greek Etymology, and on the Celtic comparisons in Bopp's Comparative Grammar, with notes on some recent Irish publications, Calcutta, 1875. Nigra, Caval. C.: *Glossæ Hibernicæ veteres codicis Taurinensis*, Lutetia Parisiorum, 1869; and *Reliquie Celtice*—I. II *Manoscritto Irlandese di S. Gallo*, Torino 1872 (this gives the marginal notes in *Ogam* from the St Gall MS.). Prof. G. L. Ascoli is bringing out the Irish Glosses at Milan.

Annals, &c.—O'Connor's *Rerum Hibernicarum Scriptores Veteres*, London, 1814-1825, 1826, 4 vols. *Annals of the Four Masters*, edited, with a translation and copious notes, by O'Donovan, 7 vols., Dublin, 1851. *Chronicon Seotorum*; a chronicle of Irish affairs from the earliest times to 1135 A.D., with a supplement containing the events from 1141 to 1150, edited, with a translation, by W. M. Hennessy, London, 1866. The *Annals of Loch Cé*: a chronicle of Irish affairs from 1014 A.D. to 1590 A.D., edited, with a translation, by Hennessy. The *War of the Gaedhil* with the *Gail*, or, the Invasions of Ireland by the Danes and other Norsemen, edited, with a translation, by Dr Todd, Dublin, 1857.

¹ See Villari, *Antiche legende e tradizioni che illustrano la Divina Commedia*, Pisa, 1865.

Literature.—O'Reilly, Edward: A chronological account of nearly four hundred Irish writers, commencing with the earliest account of Irish history, and carried down to the year of Our Lord 1760; with descriptive catalogue of their extant works, Dublin, 1820. O'Connor, Rev. Charles, D.D.: Bibliotheca MS. Stowensis, a descriptive catalogue of the manuscripts in the Stowe Library, 2 vols., and an appendix to vol. I., Buckingham, 1818, 1819. The Transactions of the Gaelic Society of Dublin, vol. I., Dublin, 1828, contain *Deirdre*, or the lamentable fate of the sons of *Uisnech*, with a translation by O'Flanagan. O'Curry, Eugene: Lectures on the Manuscript Materials of Ancient Irish History, Dublin, 1861. On the manners and Customs of the Ancient Irish, A Series of Lectures, edited by W. K. Sullivan, Ph.D., 3 vols., London, 1873. Brooke, Miss Charlotte: Reliques of Irish Poetry, consisting of Heroic Poems, Odes, Elegies, and Songs; translated into English verse, with notes, Dublin, 1789. Hardiman, James: Irish Minstrelsy or Bardic Remains of Ireland, with English poetical translations, 2 vols., London, 1831. Ossianic Society, Transactions of, 6 vols., Dublin, 1851-1861, containing nearly all the tales yet printed of the Ossianic Cycle. Celtic Society, Publications of:—*Leabhar na g-Ceart*, The Book of Rights, translated by O'Donovan, 1817; *Cumbrensis Eversus*, 3 vols., 1848-52; Miscellany of the Celtic Society, 1819; *Cath Mhuighe Leana*—The Battle of *Magh Leana*, together with the *Tochmarc Móméra*, or the Courtship of *Móméra*, translated by Eugene O'Curry, 1855. Irish Archaeological Society, Publications of:—Tracts relating to Ireland, vol. I., containing The Circuit of Ireland, by *Muircheartach MacNeill*, a poem of the 10th century; *Cath Muihri Rath*, the Battle of *Magh Rath*, with translation by O'Donovan; Account of the Tribes and Customs of the District of *Ity-Many*, commonly called O'Kelly's Country, with translation and notes by O'Donovan. Account of the Tribes and Customs of the District of *Ity Fiachrach*, with translation and notes by O'Donovan. The Miscellany of the Irish Archaeological Society (this contains an ancient poem attributed to St Columcille, with a translation by Dr O'Donovan, Irish Charters, &c.); The Irish version of the *Historia Britonum* of Nennius (or as it is called in Irish MSS. *Leabar Bretnach*, the British Book), edited, with a translation and notes, by Rev. Dr Todd, and an Introduction and additional notes, by the Hon. Algernon Herbert. Irish Archaeological and Celtic Society (publications of the Amalgamated Societies):—*Liber Hymnorum*, the Book of Hymns of the Ancient Church of Ireland, Parts I and 2, edited by Todd; Life of St Columba by Adamnan, ninth Abbot of Ily, edited by Reeves; Three Fragments of Ancient Irish Annals, edited, with translation and notes, by O'Donovan; The Topographical Poems of *Sean O'Dubhagáin* and *Gilla-na-Naomh O'Uaidhrin*, edited, with translation and notes, by O'Donovan; *Féile na Naomh n-Erennach*, or Calendar of Native Saints of Ireland, usually styled the martyrology of Donegal, with a translation by Dr O'Donovan, and notes, &c., by Drs Todd and Reeves. The Book of *Fenagh* in Irish and English, originally compiled by St Caillin, Archbishop, Abbot, and Founder of *Fenagh*, alias Duibhally of *Moy Rein*, tempore St Patrick; revised and annotated by W. M. Hennessy, and translated by D. H. Kelly, Dublin, 1875. Crowe, O'Belmo: The *Amra Choluim Chilli* of *Dallan Forgaill*, with translation, notes, &c., Dublin, 1871. Stokes, Dr Whitely: *Fis Adamnain*, Vision of Adamnan from the *Lebor na h-Uidri*, with an English translation and notes, Calcutta. The Atlantis, conducted by members of the Catholic University of Ireland, 4 vols., London, 1858-1863, contains four tales, with translations by Prof. O'Curry. Proceedings of the Royal Irish Academy—Irish MSS. series, vol. I., Part 1. (the only part published), contains two tales, with translations by Mr O'Belmo Crowe and Prof. O'Looney. The Journal of the Royal Historical and Archaeological Association of Ireland, besides many valuable papers on antiquarian and historical subjects, especially concerning the Anglo-Norman period, contains various Irish pieces, with translations by Mr O'B. Crowe. St Patrick, Life of, by M. F. Cusack; with Appendix by W. M. Hennessy. Todd, Rev. J. L., D.D.: St Patrick Apostle of Ireland, A Memoir of his life and mission, Dublin, 1861. Reeves, Rev. Wm., D.D.: The Culdees of the British Islands as they appear in History, with an Appendix of evidences, Dublin, 1864. Ferguson, Mrs M. C.: The Story of the Irish before the Conquest, from the Mythical Period to the Invasion under Strongbow, London, 1868.

GAELIC.—*Dictionaryum Scoto-Celticum*, A Dictionary of the Gaelic Language, compiled and published under the direction of the Highland Society of Scotland, 2 vols., Edinburgh and London, 1823. A Gaelic Dictionary, in two parts, to which is prefixed a new Gaelic Grammar, by R. A. Armstrong, London, 1825. MacAlpine's Pronouncing Gaelic-English English-Gaelic Dictionary, with rudiments of Gaelic Grammar, 4th ed., 2 vols., Edinburgh, 1863. The Book of Common Prayer, commonly called John Knox's Liturgy, translated into Gaelic, 1667, A.D., by Mr John Carswell, Bishop of the Isles, edited, with an English translation, by Thomas M'Lauchlan, LL.D., Edinburgh. Skene, W. F.: *Chronicles of the Picts and Scots*, Edinburgh, 1867. The Book of the Dean of Lismore, a selection of ancient Gaelic Poetry from a manuscript collection made by Sir James M'Gregor, Dean of Lismore, in the beginning of the 16th century, edited, with a translation and notes, by the Rev. Thomas M'Lauchlan, and an Introduction and additional notes by William F. Skene, Edinburgh, 1862. Campbell, J. F.: *Popular Tales of the West Highlands orally collected*, with a translation, 4 vols., Edinburgh, 1860-1862. *Leabhar na Feinne*, vol. I.—Gaelic text; Heroic Gaelic Ballads collected in Scotland from 1572 to 1871, copied from old MSS. and rare books, and orally collected since 1859, with lists of the collections and an account of the documents quoted, by Campbell of Islay; privately printed, 1872.

MAXX.—Kelly, Rev. J.: A practical Grammar of the ancient Gaelic, or language of the Isle of Man, usually called Manx, edited, together with an Introduction, Life of Dr Kelly, and notes, by Rev. W. Gill, 1870. *Manx Dictionary*, in two parts—*Fockleir Mannagh us Baurlagh*; edited by Rev. W. Gill, 1866.

WELSH.—*Language*, &c.—*Dosparth Edeyrn Dared Iur*, or the ancient Welsh Grammar, which was compiled by royal command in the 13th century by *Edeyrn*, the Golden-Tongued, to which is added *y Puan Llyfr Kerdduriaeth*, or the rule of Welsh poetry, &c., with English translation and notes by the Rev. John Williams Ab Ithel, Llandover, 1856, 8vo. Rowland, Rev. Thomas: A Grammar of the Welsh Language, 2d ed., London, 1857. A Dictionary of the Welsh Language, to which is prefixed a Welsh Grammar, by W. Owen Pughe, 2 vols., 2d ed., Denbigh and London, 1822.

History, Annals, Laws, &c.—*Gildas de Excidio Britanniae*, London, 1838. The *Historia Britonum* commonly attributed to Nennius; from a manuscript lately discovered in the library of the Vatican Palace at Rome, edited in the 10th century by Mark the Hermit; with an English version, &c., by the Rev. W.

Gunn, London, 1819. Nennil *Historia Britonum*, London, 1838. A more correct text from the Vatican MS. appears in Appendix ad opera edita ab Angelo Maio, Romæ, 1871. *Historia Britannica*, Saxonica, Anglo-Danica, Scriptores XV. ex vetustis Codd. MSS. editi opera Thomæ Gale, Oxon, 1691. (The first article contains Gildas's work.) *Monumenta Historica Britannica*, or Materials for the History of Britain from the earliest period to the end of the reign of King Henry VII.; vol. I. (as far as the Norman Conquest), 1848, fol. Wright, Thomas: *Biographia Britannica Literaria*—Anglo-Saxon Period; London, 1842 (Gildas, Nennius, St Columbanus). Gottfried's von Monmouth *Historia Regum Britanniae* mit literarhistorischer Einleitung und ausführlichen Anmerkungen, und *Brut Tysilio*, Altwälsche Chronik in deutscher Uebersetzung, herausgegeben von Sam-Murto (A. Schulz), Halle, 1854. Six Old English Chronicles, edited, with illustrated notes, by J. A. Giles, London, 1848. *Annales Cambriae*, edited by the Rev. John Williams Ab Ithel, London, 1860 (Chronicles and Memorials of Great Britain and Ireland); this edition brings down the Annals to 1288, that in the *Monumenta Historica* only to 1066. *Brut y Tywysogion*, or The Chronicle of the Princes, edited by the Rev. John Williams Ab Ithel, London, 1860, (Chronicles and Memorials of Great Britain and Ireland); this edition comes down to 1288, that in the *Monumenta Historica* only comes down to 1066. Roberts, Rev. Peter, A.M.: The Chronicle of the Kings of Britain, translated from the Welsh copy, attributed to *Tysilio*, collated with other copies and illustrated with copious notes, to which are added original dissertations on the following subjects, viz., on the history and epistle attributed to Gildas, on the authority of the *Brut*, on the primary population of Britain, on the laws of *Dyfnwal Moelmud*, and on the Ancient British Church, London, 1811, 4to. Ancient Laws and Institutes of Wales, with an English translation of the Welsh text, by Anselm Owen, 1 vol., fol., 1811; there is an 8vo ed. in 2 vols. Walter, Ferdinand: *Das Alte Wales*, Bonn, 1859.

Literature.—The *Myvyrian Archaeology (sic)* of Wales, collected out of ancient manuscripts; London, vols. I. and II., 1801; vol. III. 1807, 8vo; new issue in one vol. royal 8vo, Denbigh, 1861. Skene, William F.: *The Four Ancient Books of Wales*, containing the Cymric poems attributed to the Bards of the 6th century, 2 vols., Edinburgh, 1868. Villemarqué, Th. Hersart de la: *Poèmes des Bardes Bretons du VI^e Siècle*, Paris, 1850. Nash, D. W.: *Taliesin*, or the Bards and Druids of Britain, London, 1858. *Y Gododin*, a Poem on the Battle of Catraeth, by Aneurin, a Welsh Bard of the 6th century, with an English translation, and numerous historical and critical annotations, by Rev. John Williams Ab Ithel, Llandover, 1852. *Llywarch Hen*, Prince of the Cumbrian Britons; Heroic Elegies and other pieces in Welsh, with a literal translation by William Owen, 8vo, 1792. Stephens, Thomas: *The Literature of the Kymry*, being a critical essay on the History of the Language and Literature of Wales, &c., Llandover, 1819. *Iolo Manuscripts*, a selection of ancient Welsh manuscripts in prose and verse from the collection made by the late Edward Williams, *Iolo Morganwg*, Llandover, 1848. Williams, Edward (*Iolo Morganwg*): *Cyfrinach Beirdd gwyn Prydain*, edited by his son Taliesin Williams, 8vo, 1829. Lewis Glyn Cothi, Poetical works of, in Welsh, edited, with notes, &c., by the Revs. W. Davies and J. Jones, Oxford, 1837. Jones, Rhys: *Gorchestion Beirdd Cymru; new Flodan godidow-grydd awen*, Amwythig, 1773 (Poetry of the 15th century). Huw Morus: *Eos Ceiriog*, 2 vols. 12mo, Wrexham, 1823 (Poems of the Welsh Cavalier poet). Evans, Rev. Evan: Some specimens of the poetry of the ancient Welsh Bards translated into English, with notes, &c., London, 1764. The Physicians of Myddval, *Meddygon Myddval*, or the medical practice of the celebrated Rhilwallon and his sons of Myddval, &c., translated by Pughe, and edited by Williams Ab Ithel, Llandover, 1861. Williams, Rev. Robert, M.A.: *Encyclopaedia Cymru*, a biographical dictionary of eminent Welshmen, Llandover, 1862. Rees, Rev. W. J.: *Lives of the Cambro-British Saints of the 5th and immediately succeeding centuries*, Llandover, 1853. Rees, Rev. Rice, M.A.: *An Essay on the Welsh Saints*, or the primitive Christians, usually considered to have been the founders of churches in Wales, London, 1836. The *Cambro-Briton*, 3 vols. 8vo, London, 1820-1822. Transactions of the Cymmrodorion, or Metropolitan Cambrian Institution, London, 1822, 1823-1813. *Archæologia Cambrensis*, a journal which worthily sustains the cause of Cymric literature and archaeology, commenced in 1846.

Prose Tales and Arthurian Romances.—The *Mabinogion* from the *Llyfr Coch O'Hergest* and other ancient Welsh manuscripts, with an English translation and notes, by Lady Charlotte Guest, 3 vols., London, 1849. Villemarqué, Le Vicomte Th. Hersart de la: *Les Romans de la Table Ronde et les Contes des Anciens Bretons*, 3d ed., Paris, 1860; and *Myrdhin*, ou L'Enchanteur Merlin, son histoire, ses amours, son influence, Paris, 1865. San-Marte (A. Schulz): *Die Sagen von Merlin*, Halle, 1853; An Essay on the Influence of Welsh Tradition upon the Literature of Germany, France, and Scandinavia, Llandover, 1841.

Neo-Druidism.—Williams, Edward (*Iolo Morganwg*): *Barddas*, Llandover, 1862. Davis, Rev. Edward: *Celtic Researches on the Origin, Traditions, and Language of the Ancient Britons*, London, 1801; 2d ed., 1807. The Mythology and Rites of the British Druids ascertained by National Documents, with remarks on ancient British Coins, London, 1809. Britannia after the Romans; being an attempt to illustrate the Religious and Political Revolutions of that Province in the fifth and succeeding centuries (by Algernon Herbert), 2 vols., London, 1836-1841. Cyclops Christianus, by Algernon Herbert, London, 1819.

Cousins.—Williams, Rev. Robert: *Lexicon Cornu-Britannicum*, Dictionary of the ancient Celtic of Cornwall, with Synonyms in Welsh, Armoric, Irish, Gaelic, and Manx, Llandover, 1862-65. Stokes, Whitely: A Cornish Glossary; Note on Endlicher's Gmüth Glossary; The Accusative Plural in the British Language, London, 1870. Norris, Edwin: *The Ancient Cornish Drama*, 2 vols., Oxford, 1859. *Paseon agan Artuth*, The Passion of our Lord, a Middle Cornish Poem, edited, with a translation and notes, by W. Stokes, Berlin, 1862. *Gureans* an *Bys*, The Creation of the World, a Cornish Mystery, edited, with translation and notes, by Stokes. *Poivhele*: Language, Literature, and Literary Characters of Cornwall, with a Cornish-English Vocabulary, 1806-8.

ANNALE ON BRETONS.—Le Comte: *Dictionnaire Breton-Français et Français-Breton*, edited by the Vicomte Hersart de la Villemarqué, 2 vols. 4to, Saint Brieuc, 1847-50. Troude, Le Col.: *Dictionnaire Français-Breton*, Brest, 1869. Supplément aux Dictionnaires Bretons, Landernau, 1872. Hingant, L'Abbé: *Éléments de la grammaire bretonne*, Trégulier, 1869. *Duhez Santez Nonn*, ou *Éléments de la grammaire bretonne*, Trégulier, 1869. *Duhez Santez Nonn*, ou *Vie de Sainte Nonne*, et de son fils Saint Devy; Mystère composé en langue

bretonne antérieurement au 12^{me} Siècle, with an Introduction by the Abbé Sionnet, and translated by Le Gonidec, Paris, 1837. Villemarqué, Le Vicomte Harsart de la: *Burzud braz Jezuz*, Le Grand Mystère de Jésus, Passion et Resurrector; Dramé Breton du Moyen Age, avec une étude sur le Théâtre chez les Nations Celtiques, 1 vol. 8vo, Paris, 1865; and *Barzaz-Breiz*, Chants Populaires de la Bretagne, recueillis et publiés avec une traduction française, une introduction, une conclusion, des éclaircissements, et les mélodies originales, 2 vols. in 18mo, 6^{me} ed., Paris Luzel, F. M.: Chants Populaires de la Basse

Bretagne, 2 vols. Lorient, 1868-1874; and Sainte Tryphine et le Roi Arthur; Mystère Breton, en deux journées et en huit actes, traduit, publié, et précédé d'une introduction par F. M. Luzel, &c., Quimperlé et Paris, 1863, Contes Bretons, recueillis et traduits par M. F. Luzel, sm. 8vo., Quimperlé, 1870. Stokes, Whitley: Middle-Breton HOURS, edited, with a translation and glossarial index, Calcutta, 1876. *Gwerzion Breiz-izel ar Muvrañter Brezounek*, Le Conteur Breton, ou Contes Bretons recueillis par le Col. A. Troude et G. Mlin, 1 vol. 12mo, Brst, 1870. (W. K. S.)

CEMENTS, substances employed to unite together by their solidification from a soft or liquid state, and without mechanical rivets, things of the same or of different kinds. Stony cements may be natural, as the lime employed for mortar, and the so-called Roman cements; or they may be artificial, as Portland cement, made by calcining mixtures of chalk with clay or river-mud (see BUILDING, vol. iv. p. 459) Roman contains more clay than Portland cement, and sets more rapidly. A good artificial water cement is obtained by heating for some hours to redness a mixture of 3 parts of clay and 1 part of slaked lime by measure. Another hydraulic cement may be made by mixing powdered clay and oxide of iron with water. A very hard stone cement is prepared from 20 parts of clean river sand, 2 of litharge, 1 of quicklime, worked into a paste with linseed-oil. Paper-pulp, mixed with size and plaster of Paris is used for moulded ornaments. *Keene's marble cement* is plaster of Paris which has been steeped in strong solution of alum or sulphate of potash, and calcined and ground. It is slaked with alum solution when used. In *Martin's cement*, pearl-ash is employed as well as alum. *Parian cement* contains borax. *Selenitic cement* is a mixture of calcined gypsum, sand, and hydraulic lime. A cement used for cracks in boilers is a mixture of clay 6 parts and iron filings 1 part with linseed-oil. For steam-joints, ox-blood thickened with quicklime is employed. The *iron-rust cement* consists of 100 parts of iron turnings, with 1 part of sal-ammoniac; this is an excellent cement for iron-work. For water-tight joints, equal parts of white and red lead are worked into a paste with linseed-oil. A serviceable packing for connecting pipes, making joints, filling cracks in retorts, &c., may be made by adding to asbestos powder enough of liquid silicate of soda to form a thick paste; the composition hardens rapidly, stands great heat, and prevents the escape of acid vapours. Cracks in glass vessels required to resist heat and moisture may be stopped by covering them with strips of hog's or bullock's bladder, which are affixed by means of a paste of caseine dissolved in cold saturated solution of borax; after drying, the repaired portions are made capable of withstanding heat by an outside coating of a mixture of concentrated solution of silicate of soda with plaster of Paris or quicklime.

A strong cement for alabaster and marble, which sets in a day, may be prepared by mixing 12 parts of Portland cement, 8 of fine sand, and 1 of infusorial earth, and making them into a thick paste with silicate of soda; the object to be cemented need not be heated. For stone, marble, and earthenware a strong cement, insoluble in water, can be made as follows: skimmed-milk cheese is boiled in water till of a gluey consistency, washed, kneaded well in cold water, and incorporated with quicklime; the composition is warmed for use. A similar cement is a mixture of dried fresh curd with $\frac{1}{10}$ th of its weight of quicklime, and a little camphor; it is made into a paste with water when employed. A cement for Derbyshire spar and china, &c., is composed of 7 parts of resin and 1 of wax, with a little plaster of Paris; a small quantity only should be applied to the surfaces to be united, for, as a general rule, the thinner the stratum of a cement, the more powerful its action. Quicklime mixed with white of egg, hardened

Canada balsam, and thick copal or mastic varnish are also useful for cementing broken china, which should be warmed before their application. For small articles, shell-lac dissolved in spirits of wine is a very convenient cement. Cements such as marine glue are mixtures of shell-lac and India-rubber, or of their solutions.

There are various cements for wood. For wooden cisterns a mixture is made of 4 parts of linseed-oil boiled with litharge, and 8 parts of melted glue; other strong cements for the same purpose are prepared by softening gelatine in cold water and dissolving it by heat in linseed-oil, or by mixing glue with $\frac{1}{2}$ of its weight of Venice turpentine. Solution of shell-lac in ammoniac has been proposed by Mons. C. Mène for the attachment of caoutchouc to wood and metals. *Mahogany cement*, for filling up cracks in wood, consists of 4 parts of beeswax, 1 of Indian red, and yellow-ochre to give colour. *Cutlers' cement* is made of equal parts of brick-dust and melted resin, and is used for fixing knife-blades in their hafts. A cement used in electrical apparatus is composed of 4 parts by weight each of red ochre and beeswax, 20 parts of resin, and 1 part of plaster of Paris; these are melted together till smooth. For covering bottle-corks a mixture of pitch, brick-dust, and resin is employed. A cheap cement, sometimes employed to fix iron rails in stone-work, is melted brimstone, or brimstone and brick-dust. *Japanese cement*, for uniting surfaces of paper, is made by mixing rice-flour with water and boiling it. *Jewellers' cement* contains 3 parts of isinglass made soft in water, and 1 part of gum ammoniacum; these are heated together till a drop of the mixture stiffens immediately on cooling. Gold and silver chasers keep their work firm by means of a cement of pitch and resin, a little tallow, and brick-dust to thicken. *Temporary cement* for lathe-work, such as the polishing and grinding of jewellery and optical glasses, is compounded thus:—resin, 4 oz.; whitening previously made red-hot, 4 oz.; wax, $\frac{1}{2}$ oz. Mastic alone is much employed for cementing and mending gems. In Turkey, jewellery for the ornamentation of weapons and trinkets is secured by a composition thus made:—two small bits of gum galbanum or gum ammoniacum are dissolved by trituration in 2 oz. of a glue prepared by digesting softened isinglass in spirits, and the mixture is incorporated at a gentle heat with a thick alcoholic solution of a little gum mastic. This cement is kept in closely-stoppered phials, which must be immersed in warm water when the cement is to be liquefied for use.

(1847); Burnell's *Rudimentary Treatise on Limes, Cements, &c.*, Weale's series (1866); Reid's *Practical Treatise on the Manufacture of Portland Cement* (1863); Cooley's *Cyclopaedia of Practical Receipts*, edited by Tuson, pp. 305-311 (1872); Gwilt's *Encyclopaedia of Architecture*, edited by Papworth, §§ 1863 et seq., 2231i, 2251a et seq. (1876).

CEMETERY (κοιμητήριον, from κοιμάω, to sleep), literally a sleeping-place, was the name applied by the early Christians to the places set apart for the burial of their dead. These were generally extra-mural and unconnected with churches, the practice of interment in churches or churchyards being unknown in the first centuries of the Christian era. The term cemetery has, therefore, been

appropriately applied in modern times to the burial grounds, generally extra-mural, which have been substituted for the overcrowded churchyards of populous parishes both urban and rural.

From 1840 to 1855, attention was repeatedly called to the condition of the London churchyards by correspondence in the press and by the reports of Parliamentary committees, the first of which, that of Mr Chadwick, appeared in 1843. The vaults under the pavement of the churches, and the small spaces of open ground surrounding them, were literally crammed with coffins. In many of the buildings the air was so tainted with the products of corruption as to be a direct and palpable source of disease and death to those who frequented them. In the churchyards coffins were placed tier above tier in the graves until they were within a few feet (or sometimes even a few inches) of the surface, and the level of the ground was often raised to that of the lower windows of the church. To make room for fresh interments the sextons had recourse to the surreptitious removal of bones and partially-decayed remains, and in some cases the contents of the graves were systematically transferred to pits adjacent to the site, the grave-diggers appropriating the coffin-plates, handles, and nails to be sold as waste metal. The daily papers of thirty years ago contain numerous records of scandals of this kind; while from the official reports it appears that the neighbourhood of the churchyards was always unhealthy, the air being vitiated by the gaseous emanations from the graves, and the water, wherever it was obtained from wells, containing organic matter, the source of which could not be mistaken. The vaults of many of the London churches are still crowded with coffins deposited in them during this period of intra-mural interments. In the vault of Bow Church, Cheapside, the leaden coffins form a huge mass 30 feet high, covered with fungi and cobwebs. In all the other large towns the evil prevailed in a greater or less degree, but in London, on account of the immense population and the consequent mortality, it forced itself more readily upon public attention, and after more than one partial measure of relief had been passed the churchyards were, with a few exceptions, finally closed by the Act of 1855, and the cemeteries, which now occupy a large extent of ground to the north, south, east, and west, became henceforth the burial places of the metropolis. Several of them had been already established by private enterprise before the passing of the Burial Act of 1855 (Kensal Green Cemetery dates from 1832), but that enactment forms the epoch from which the general development of cemeteries in Great Britain and Ireland began. Burial within the limits of cities and towns is now almost everywhere abolished, and where it is still in use it is surrounded by such safeguards as make it practically innocuous. At a large expenditure of money London and most of our chief provincial cities and towns have been provided with spacious and well-situated cemeteries, which are under the supervision of the Local Burial Boards and of the inspectors appointed by Government, and anything like a recurrence to the scandalous state of things which existed as late as twenty-five years ago is now impossible.

But though there need be no fear of retrogression there may be a change in another direction. Our present system of burial has been made the subject of very severe strictures on the part of Sir Henry Thompson and others, and it has been proposed that we should abandon inhumation altogether and return to the ancient practice of cremation. We shall not discuss this proposal here, as the importance of the subject requires a separate treatment, but we must briefly refer to the criticisms upon our cemeteries to which it gave rise. The practice of burial has been very ably defended by Mr Holland, M.R.C.S.,

who as Medical Inspector of Burials for England and Wales has perhaps a greater practical knowledge of the subject than any other man living, and on the same side were found Dr Richardson and Mr Seymour Haden, who proposed, however, some important modifications of the system with a view to its improvement. Amongst the objections urged against the present practice, it is alleged that in three ways our cemeteries are a source of danger to the health of the living, viz. :—(1) by the gases rising from the surface of the soil causing air-pollution; (2) by their drainage introducing noxious matter into wells used for drinking purposes; (3) by the possibility that the re-opening of ground in which persons who have died of an infectious disease are interred might sometimes be the means of reproducing an epidemic. Now there is really no evidence in support of these serious allegations; on the contrary there is much concurrent testimony which tends to completely discredit them. Of course it is not for a moment contended that cemeteries may not be mismanaged so as to become a source of danger. But this is beside and beyond the question, for in a matter of this kind we cannot argue from individual cases of abuse against the general use, and under the existing system of inspection and superintendence, with local authorities in every district specially charged with the care of the public health, it is difficult to see how any dangerous case of mismanagement could be allowed to develop itself without becoming the subject of immediate investigation and reform. Only very ordinary precautions are required to render a cemetery perfectly safe. "If," says Mr Holland, "no more dead be buried in the soil than the free oxygen contained in rain and dew carried through it will decompose, and if such soil be left undisturbed until the process of decay is completed, and if, as is almost certain to be the case, the use of such ground for burial be discontinued at latest when it becomes full of the remains that do not decay, and probably long before, such places will be neither harmful while they are used for burial, nor anything but beneficial when such use of them is discontinued, as then they will become large decorative gardens or small parks—reservoirs of fresh air." With regard to the alleged peril from air-pollution, it may be replied that there can be no danger so long as the dead are laid in a sufficient space of properly planted ground, and at a moderate distance from any considerable number of houses, and for this purpose a mile is quite sufficient. The gases evolved are to a great extent absorbed by the vegetable produce of the soil, and what little does filter upwards and escape from the surface of the ground cannot accumulate to any pernicious extent, and must necessarily be dispersed and diluted in the air. Who ever perceives any unpleasant odour in a well-kept cemetery? Yet if danger were present the sense of smell would give unmistakable warning of it. As to the question of water-pollution, especial care is always taken to study the drainage of our cemeteries with reference to the neighbouring sources of water supply. Shallow surface wells near a cemetery are open to suspicion, as the water may be tainted by organic matter filtering through the soil, but suspected wells can be closed by the authorities, and it must be remembered that shallow wells are nearly always dangerous whether they are near cemeteries or not. Deep wells are almost invariably safe even near a cemetery, and in most places the water is brought from a distance in mains in such a way that pollution from cemeteries is impossible. As to the danger of infection, if it existed anywhere, assuredly we should have some practical evidence of it from the great cemeteries of the metropolis. Yet there is not a particle of such evidence forthcoming. On the contrary, it is now very generally conceded that there need be little if any

fear of infection from a dead body. Undertakers and their assistants who are continually at work among the dead are notoriously free from contagious disease, and, *a fortiori*, there can be no danger once the body is laid in the earth. It is only in very exceptional cases that it can be disturbed until many years have elapsed, and then all cause for apprehension is gone. Many of the plague-pits in the London churchyards have been reopened in places where the plague-stricken dead once lay piled in layers, and scarcely any human remains have been found, and these in such a condition that it would be impossible to imagine any infection or contagion from them.

The changes in our cemetery system which have been suggested by Mr Seymour Haden and others have all the one common object of increasing the security of safety to the public health, by facilitating and rendering perfect the decay of the buried dead, and it is proposed to accomplish this less by the use of any direct agency for accelerating the natural process, than by removing the obstacles that are at present placed in its way. Mr Seymour Haden tells us that a well-made wooden coffin is practically indestructible, and though it cannot prevent decomposition, yet it arrests it, and keeps the process long incomplete, thus considerably increasing the aggregate of decaying matter at any one time present in a cemetery, and preventing the return of "earth to earth." As a remedy he proposes that we should use wicker coffins, of the present shape, made of white or stained (but unvarnished) osiers, with large open meshes. The contents of such a receptacle could be concealed during the funeral by a graceful covering of ferns and flowers, and in cases of infectious disease, or where decomposition might commence immediately after death, the coffin could be made double with a space of two or three inches between the inner and outer basket to be filled with charcoal or some other disinfectant. Models of such coffins were exhibited by Mr Seymour Haden at Stafford House, London, the town residence of the duke of Sutherland in June 1875, and there is no doubt that if they were generally employed, the natural process of decay in our cemeteries would take place in a way that would leave even less room than at present for any evil resulting from carelessness or mismanagement on the part of the authorities charged with their superintendence, and the number of bodies actually decaying in any given cemetery would be comparatively few, so surely and effectually would the process be completed in a great majority of cases. The abandonment of the practice of burial in vaults, brick graves, and catacombs, such as those which are to be seen in many of the London cemeteries, is of course a corollary of this proposal; and whether Mr Seymour Haden's plan is adopted or not, it is quite certain that our cemeteries would be greatly improved by no more brick graves being made in them, and by the open catacombs being closed wherever they exist. Such places are very difficult to ventilate, and must frequently be the source of malarious exhalations.

Amongst other proposals which have been made it has been suggested, that when a good natural soil containing carbon does not exist the site of the proposed cemetery should be excavated to the depth of about 12 feet, and then filled up with an artificial soil composed of carbon, lime, and sand. The existence of carbon in the soil would remove any danger of water pollution through filtration from the cemetery, while the lime would tend to accelerate the resolution of the decaying matter into its original elements. This is Dr Richardson's proposal, and he further adds that the cemetery should be planted with quick-growing shrubs and ornamental grasses, the trees being confined to an encircling belt of wood, and a series of memorial tablets in an adjacent edifice being substituted for tomb-

stones and monuments. He further points out that with such a method the cemetery might be renovated after a certain number of years by substituting freshly-prepared soil for the old. But there does not seem to be any advantage in this. There must always be open spaces in and around our cities for the sake of fresh air, and a cemetery in which interments have ceased for some years, and in which the ornamental plantations were kept in good order, would form a useful park or garden. In the disposal of our dead feeling must always be allowed to be a considerable factor in the arguments for the adoption of any given plan, and it appears that in Great Britain and Ireland there would be an amount of dislike to any method which did not assign to our dead something like a lasting place of interment. This feeling does not by any means exist in some of the countries of the Continent. In one of the cemeteries of Naples numerous burials take place in a series of 365 pits. One pit is opened each day, the dead are laid in it, and it is filled with an earth containing a large quantity of lime. A year after the pit is reopened, the earth with its contents, now almost entirely decayed, is removed, fresh earth is placed in its stead, and the pit is again ready for new interments.

The chief cemeteries of London are Kensal Green Cemetery on the Harrow Road, about 2½ miles from Paddington, which has an area of 18 acres and already contains the remains of 70,000 dead; Highgate Cemetery, which occupies a considerable portion of the slope of Highgate Hill, and commands one of the best views of London; the cemetery at Abney Park (once the residence of Dr Watts), which is adorned with very fine plantations of old growth; the Norwood and Nunhead cemeteries to the south of London; the West London Cemetery at Brompton; the cemeteries at Ilford and Leytonstone in Essex; the Victoria Cemetery and the Tower Hamlets Cemetery in East London; and at a still greater distance, and generally accessible only by railway, the great cemetery at Woking near Guildford in Surrey, and the cemetery at Colney Hatch. The general plan of all these cemeteries is the same, a park with broad paths either laid out in curved lines as at Kensal Green and Highgate, or crossing each at right angles as in the case of the West London Cemetery. The ground on each side of these paths is marked off into grave

FIG. 1.—West London Cemetery, Brompton.

spaces, and trees and shrubs are planted in the intervals between them. The buildings consist of a curator's residence and one or more chapels, and usually there is also a range of catacombs, massive structures containing in their corridors recesses for the reception of coffins, generally closed only by an iron grating. The provincial cemeteries in the main features of their arrangements resemble those of the metropolis. One of the most remarkable is St James's Cemetery at Liverpool, which occupies a deserted quarry. The face of the eastern side of the quarry is traversed by ascending gradients off which open catacombs

formed in the living rock,—a soft sandstone; the ground below is planted with trees, amongst which stand hundreds of gravestones. The main approach on the north side is through a tunnel, above which, on a projecting rock, stands the cemetery chapel, built in the form of a small Doric temple with tetrastyle porticoes. Its situation, though very picturesque, is an objectionable one, for no cemetery should ever be constructed in a deep hollow. Many of the cities of America possess very fine cemeteries. One of the largest is that of Mount Auburn near Boston, which occupies upwards of 110 acres of undulating ground on the bank of the Charles River. It is formed out of an old and well-wooded estate, and consequently, unlike most modern cemeteries, its plantations consist of large well-grown trees.

The chief cemetery of Paris is that of Père la Chaise, the prototype of the garden cemeteries of Western Europe. It takes its name from the celebrated confessor of Louis XIV., to whom as rector of the Jesuits of Paris it once belonged. It was laid out as a cemetery in 1804. It has an area of about 200 acres, and contains 16,000 monuments, including those of all the great men of France of the present century—marshals, generals, ministers, poets, painters, men of science and letters, actors, and musicians. Twice the cemetery and the adjacent heights have been the scene of a desperate struggle; in 1814 they were stormed by a Russian column during the attack on Paris by the allies, and in 1871 the Communists made their last stand among the tombs of Père la Chaise; 900 of them fell in the defence of the cemetery or were shot there after its capture, and 200 of them were buried in quicklime in one huge grave, and 700 in another. There are other cemeteries at Mont Parnasse and Montmartre, besides the minor burying-grounds at Autenil, Brignolles, Passy, La Villette, &c. In consequence of all these cemeteries being more or less crowded, a great cemetery was laid out in 1874 on the plateau of Méry sur Oise, 16 miles to the north of Paris, with which it is connected by a railway line. It includes within its circuit fully two square miles of ground. The French cemetery system differs in many respects from the English. Every city and town is required by law to provide a burial-ground beyond its barriers, properly laid out and planted, and situated if possible on a rising ground. Each interment must take place in a separate grave. This, however, does not apply to Paris, where the dead are buried, forty or fifty at a time, in the *fosses communes*, the poor being interred gratuitously, and a charge of 20 francs being made in all other cases. The *fosse* is filled and left undisturbed for five years, then all crosses and other memorials are removed, the level of the ground is raised 4 or 5 feet by fresh earth and interments begin again. For a fee of 50 francs a *concession temporaire* for ten years can be obtained, but where it is desired to erect a permanent monument the ground must be bought by the executors of the deceased. In Paris the undertakers' trade is the monopoly of a company, the *Société des pompes funèbres*, which in return for its privileges is required to give a free burial to the poor.

The *Leichenhäuser*, or dead-houses, of Frankfort and Munich form a remarkable feature of the cemeteries of these cities. The object of their founders was twofold,—(1) to obviate even the remotest danger of premature interment, and (2) to offer a respectable place for the reception of the dead, in order to remove the corpse from the confined dwellings of the survivors. At Frankfort the dead-house (fig. 2) occupies one of the wings of the propyleum, which forms the main entrance to the cemetery. It consists of the warder's room B, where an attendant is always on duty, on each side of which there are five rooms A, A, well ventilated, kept at an even temperature, and each provided with a bier on which

a corpse can be laid. On one of the fingers is placed a ring connected by a light cord with a bell which hangs outside

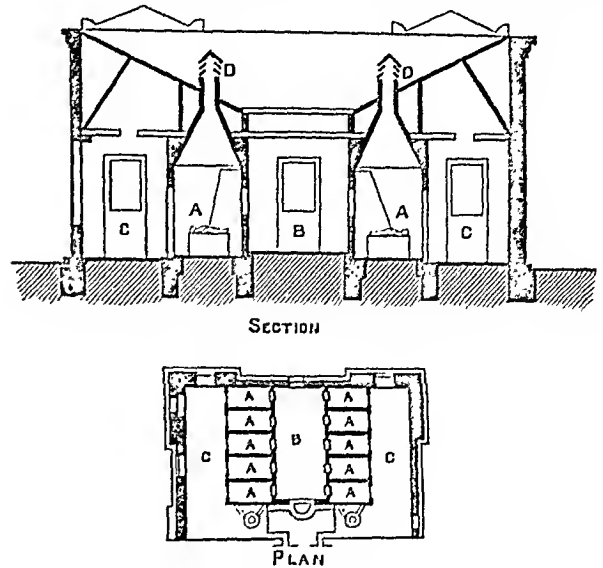

FIG. 2.—Deadhouse, Frankfort Cemetery.

in the warder's room. The use of the dead-house is voluntary. The bodies deposited there are inspected at regular intervals by a medical officer, and the warder is always on the watch for the ringing of the warning bell. One revival, that of a child, has taken place at Frankfort. The Leichenhaus of Munich is situated in the southern cemetery outside the Sendling Gate. At one end of the cemetery there is a semi-circular building with an open colonnade in front and a projection behind, which contains three large rooms for the reception of the dead. At both Frankfort and Munich great care is taken that the attendants receive the dead confided to them with respect, and no interment is permitted until the first signs of decomposition appear; the relatives then assemble in one of the halls adjoining the Leichenhaus, and the funeral takes place. In any case there is, with ordinary care, little fear of premature interment, but in another way such places of deposit for the dead are of great use in large towns, as they prevent the evil effects which result from the prolonged retention of the dead among the living. Mortuaries for this purpose are now established in many places in England.

Of the cemeteries still in use in Southern Europe the catacombs of Sicily are the most curious. There is one of these under the old Capuchin monastery of Ziza near Palermo, where in four large airy subterranean corridors 2000 corpses are ranged in niches in the wall, many of them shrunk up into the most grotesque attitudes, or hanging with pendent limbs and head from their places. As a preparation for the niche, the body is desiccated in a kind of oven, and then dressed as in life and raised into its place in the wall. At the end of the principal corridor at Ziza there is an altar strangely ornamented with a kind of mosaic of human skulls and bones.

Cemeteries have been in use among many Eastern nations from time immemorial. In China, the high grounds near Canton and Macao are crowded with tombs, many of them being in the form of small tumuli, with a low encircling wall, forcibly recalling the ringed barrows of Western Europe. But the most picturesque cemeteries in the world are those of the Turks. From them it was, perhaps, that the first idea of the modern cemetery, with its ornamental plantations, was derived. Around Constantinople the cemeteries form vast tracts of cypress woods, under whose branches stand thousands of tombstones. A grave is

never reopened; a new resting-place is formed for every one, and so the dead now occupy a wider territory than that which is covered by the homes of the living. The Turks believe that till the body is buried the soul is in a state of discomfort, and the funeral, therefore, takes place as soon as possible after death. No coffin is used, the body is laid in the grave, a few boards are arranged round it, and then the earth is shovelled in, care being taken to leave a small opening extending from the head of the corpse to the surface of the ground, an opening not unfrequently enlarged by dogs and other beasts which plunder the grave. A tombstone of white marble is then erected, surmounted by a carved turban in the case of a man, and ornamented by a palm branch in low relief if the grave is that of a woman. The turban by its varying form indicates not only the rank of the sleeper below, but also the period of his death, for the fashion of the Turkish head-dress is always changing. A cypress is usually planted beside the grave, its odour being supposed to neutralize any noxious exhalations from the ground, and thus every cemetery is a forest, where by day hundreds of turtle doves are on the wing or perching on the trees, and where bats and owls swarm undisturbed at night. Especially for the Turkish women the cemeteries are a favorite resort, and some of them are always to be seen praying beside the narrow openings that lead down into a parent's, a husband's, or a brother's grave. Some of the other cemeteries of Constantinople contrast rather unfavorably with the simple dignity of those which belong to the Turks. That of the Armenians abounds with bas-reliefs which show the manner of the death of whoever is buried below, and on these singular tombstones there are frequent representations of men being decapitated or hanging on the gallows.

See on this subject various parliamentary papers issued since 1843, London on *Cemetery Interment*, the reports of the chief cemetery companies, and the discussions on our cemetery system in reference to cremation in the *Contemporary Review* and other periodicals (1874-1875). Books of travel contain numerous descriptions of remarkable foreign cemeteries.

(A. H. A.)

CENCI, BEATRICE (1583-1599), called "The Fair Parricide," was the daughter of Francesco Cenci (1527-1598), a Roman gentleman, no less notorious for his wealth and talents than for the shameless depravity of his life and character. Born during the sack of Rome by the troops of the Constable Bourbon, Francesco Cenci began early to be talked of as a man who cared little for law and less for public opinion, and whom it were better to serve than to offend. He was the son of a Cardinal Cenci, who, as financial minister under Pius V., had contrived in that capacity to amass an immense fortune. This enabled his heir to defy the law; condemned on several occasions for murders and unnatural crimes, Francesco Cenci had always managed to escape sentence by the timely administration of enormous bribes. He was, therefore, a very profitable criminal, and one with whom several popes in succession found it to their interest to deal gently. A man of great force of character and at the same time of boundless passions, in the service of which his fine intellect and indomitable courage were wholly employed, he was one of those personalities, interesting by sheer weight of depravity, in which the Italy of the Renaissance abounded. He is distinguishable, however, from his rivals in villainy by an entire absence of ambition except of a sensual kind.

The pampering of his every appetite would seem to have induced in him its natural result,—the infinite perversity known to psychologists as a common consequence of the weariness that follows satiety. Francesco Cenci was twice married; by his first wife he had had seven children, one of whom had died in infancy; his second wife, Lucrezia Petroni, was childless. One of the strangest

sides of his horrible character was the intensity of hatred with which he regarded his surviving children. The three eldest, Giacomo, Cristoforo, and Rocco, he had sent to a Spanish university, where he kept them penniless and starving, till they could bear no more, and returned. His conduct towards them remained unchanged. Shortly before the commencement of that episode of his life with which the name of his daughter Beatrice is inseparably connected, he was imprisoned for the third and last time, and his three sons presented a petition to the Pope reigning, Clement VIII., imploring him, for the sake of the honour of their house, to make an end of their father. Clement, however, wanted money, and Francesco Cenci was released. His hate for his children was by no means lessened by this circumstance. Of his sons he never spoke but with curses; his two daughters he was in the habit of beating violently. The elder sister, however, found means to get a petition presented to Clement, in which she prayed to be removed to a convent. The Pope took pity on her, and gave her in marriage to a gentleman of Gubbio, obliging her father to dower her largely. Cenci was furious. He shut his daughter Beatrice, then aged fourteen, in a lonely room, where he visited her to bring her food, to beat her, and to revile her with her sister's flight. It is said that it was in this place and under these circumstances that Francesco Cenci conceived the monstrous passion that resulted in his death.

Meanwhile Rocco Cenci had been assassinated, and a year afterwards his brother Cristoforo met with a like fate. Thereafter Francesco Cenci, whose joy at the news of his sons' death is recorded to have been awful, ceased not to torture his unhappy wife and unhappier daughter to the utmost. The ordeal must indeed have been a terrible one that could have transformed the gay light-hearted girl-humorist into the grand woman who was afterwards to play such a notable part in crime and expiation. The accounts of Cenci's conduct with her are not to be repeated. Meanwhile, however, a certain cardinal, Monsignor Guerra, one of the handsomest men in Rome, had fallen in love with her, and was in the habit of visiting the Palazzo Cenci whenever Francesco left it. Maddened by the failure of a petition for the redress of their wrongs, which they had addressed to Clement, and which had miscarried, Lucrezia and Beatrice turned for aid to the cardinal, and communicated to him their design of ending their troubles by the murder of the author of them. The cardinal allowed himself to be persuaded; he lost no time in sounding Giacomo Cenci, the elder brother, and, after Francesco, head of the house, without whose consent nothing could be attempted. Meetings were held in a room in the cardinal's palace, and the advice of Lucrezia and Beatrice was taken on all points. For the execution of the design determined on, choice was made of two of Cenci's vassals, Olimpio and Marzio, both of whom were violently incensed against their master,—Marzio out of pity for his mistresses, and Olimpio for his own wrong's sake. It was at first proposed to cloak the murder in an attack and robbery by banditti. A dozen men were to be held in readiness to stop Francesco Cenci on his way to Petrella, a fief within the Neapolitan frontier, whether he was wont to betake himself in the summer. An enormous ransom was to be asked, with the alternative of death; the mother and daughter were to return to Rome to obtain the sum; and the assassins were to carry their threat into execution. But the scheme miscarried; Francesco reached Petrella in safety, and the conspirators were forced to arrange other combinations.

The old man's treatment of his wife and daughter grew worse daily. He is said to have pretended that he believed them pleased and happy in his gray hairs and declining

years, and to have tormented them with an incomparable ingenuity and ferocity. Beatrice at last found means to communicate with Monsignor Guerra, and it was agreed that, for the sum of a thousand piastres, one-third to be paid by the cardinal and the rest by Beatrice and Lucrezia, Olimpio and Marzio should enter the castle and kill Francesco in his bed. On September 9, 1588, accordingly, a strong opiate having been dexterously administered to the tyrant, the assassins were introduced into his chamber by Beatrice herself. Here they were overtaken with remorse; the spectacle of the old man sleeping was too much for them; and they retreated without accomplishing their intent. Beatrice, however, whose magnificent personality had risen to the occasion, received them with such indignation, that they returned and slew the sleeper, much as Jael had slain Sisera, by driving a long nail through the eye into the brain, making assurance doubly sure by driving another through the throat. When this was done Beatrice presented them with a purse of money, and clothed Marzio in a mantle lined with gold, which had belonged to her father. She and Lucrezia then withdrew the nails from the corpse, which they folded in a sheet, and dragged through several rooms to a gallery looking into an unused garden, whence they flung it into the branches of a great elder tree that grew thereby. This gallery was used for such a purpose as would lend reality to the story they intended to tell, of Cenci's leaving his bed to repair thither, and of his slipping and falling accidentally into the branches below.

Everything occurred as Beatrice and her mother had foreseen. The alarm was great, but Francesco's death was accounted for naturally enough; his remains received an honourable burial, and the two women returned to Rome, and lived tranquilly there for several months. Suspicion, however, had been excited in Naples by the circumstances of the event, and a magistrate was sent to Petrella, who arrested all the people employed about the castle. Among them was a washerwoman to whom Beatrice had given the soiled linen from Cenci's bed, with a story accounting in quite a natural way for the presence of so much blood. The woman, interrogated as to the credibility of the story, threw doubts upon it, basing her opinion on the unusual brightness of colour of the marks. Details of the interrogatory were sent to Rome, but no notice was taken, and Lucrezia and her children remained undisturbed. Meanwhile, however, Monsignor Guerra, as soon as he was informed of what was passing at Naples, had sent out emissaries charged with the murder of Francesco Cenci's assassins. Olimpio alone had been dispatched. Marzio, arrested by the Neapolitan Government several months after the murder, was taken to Naples; he confessed everything.

On information being conveyed to Rome, Lucrezia and her three step-children, Giacomo, Bernardo, and Beatrice Cenci, were arrested. Lucrezia, Giacomo, and Bernardo were taken to the Corte Savella prison, while Beatrice was confined to the Cenci Palace, and guarded strictly by a troop of *sbirri*. Marzio, meanwhile, was brought from Naples, and confronted in the Corte Savella with Lucrezia and her daughter. The majesty and strength of Beatrice in this interview were such that the old vassal withdrew his confession, and chose rather to expire under torture than to incriminate his mistresses further. In the absence of any other proof, the whole of the Cenci family were relegated to Sant' Angelo, where they remained for several months. At the end of that time Olimpio's assassin was arrested, and confessed as much as he knew. Monsignor Guerra fled from Rome, disguised as a charcoal-burner, and Lucrezia and her children were taken back again to the Corte Savella.

Put to the torture, Giacomo and Bernardo at once confessed the crime and their share in it. Lucrezia, too, who was of a luxurious habit of body, was not able to endure the torture of the cord, and acknowledged her complicity also. But Beatrice was not made of such penetrable stuff. The cord made no impression on her whatever, and her genius and force of will so confounded Moscati, the judge charged with her interrogatory, that he made her the subject of a special report to the Pope. The examination was committed to a second of sterner reputation, and Beatrice was questioned by suspension by the hair. While in this posture her brothers and Lucrezia were introduced into the apartment. All of them urged her to confess. She reproached them with their little care for the honour of the family, but at last consented. She then answered the judge's questions, denying the false and explaining the true. On the release of Beatrice from the torture and the examination, the four dined and spent the evening cheerfully together. Next day the two brothers were taken to the Tor di Nono, the women remaining in the Corte Savella; the Pope, having read the papers, had sentenced them to immediate death.

Immense efforts were made to obtain a commutation of the sentence, but a respite of twenty-five days was all that could be got. On the twenty-fifth day a body of advocates, among whom was the celebrated jurist Farinacci, presented themselves before Clement, to plead the cause of the accused; the Pope, however, refused to listen to them, and Farinacci alone was allowed to speak. They left their briefs, which Clement spent the night in reading. The next day all four prisoners were ordered to be confined *au secret*, and great hopes were entertained of pardon. But a scandalous case of matricide intervened; the assassin fled, and the Cenci were immolated in his stead, Farinacci succeeding after great efforts in saving the life of Bernardo, the youngest boy.

On the 11th of September 1599, the four prisoners were conveyed to the scaffold. Lucrezia and Beatrice were on foot; Giacomo was drawn in a cart, and was subjected the whole way to the torture of the pincers, which he bore with great fortitude. Bernardo, who was young and long-haired, was extremely agitated, and was several times mistaken for Beatrice, who indeed was far from sharing her brother's weakness. The heat was intense, the excitement unparalleled, the crowd enormous; several deaths from fever and sunstroke are said to have occurred during the day. Lucrezia and Beatrice were beheaded, and were afterwards buried, the one in the church of San Giorgio, the other in that of San Pietro in Montorio. Giacomo was *mazzolato*—killed with a mace. Bernardo, who fainted several times, was removed to a convent,—“Oriental precautions” being taken, it is said, to prevent his disturbing the new owners in their possession of the confiscated estates of his house.

Part of these estates, conveyed to a cardinal nephew of Clement, became the Villa Barberini. Therein are still preserved the portraits of Lucrezia Petroni and of Beatrice Cenci, the latter of which is said to be by Guido Reni. Shelley's fine tragedy is well known; the poet has dealt freely with much of his material, but the result is of unapproachable excellence. See also the *Chroniques et Nouvelles* of H. Beyle, whose account of the Cenci forms a remarkable page in a remarkable book.

CENEDA, a district in the province of Treviso, Northern Italy, so called from the city of the same name. Its population has varied as follows:—1807, 22,718; 1844, 18,986; 1855, 37,510; 1862, 38,413. It is a highly picturesque region at the foot of the Alps, fertile in corn and wine, the white kind of which has considerable local celebrity. The olives which formerly abounded have almost disappeared. There are saline springs near the

town, which are among the richest in iodine of any known, the proportion being 0.4032 of iodine in 10,000 parts of water. They are much used by the inhabitants of the neighbouring districts. The little city of Ceneda is charmingly situated on the last slope of the hills inclined from west to east, and has the reputation of being especially healthy. The Emperor Berengarius held a court of justice here, when he gave by diploma to the bishop of Ceneda, which had its own body of statutes compiled in 1339 and published in 1609, the jurisdiction of the whole territory lying between the rivers Piave and Livenza from the Alps to the sea. In the cathedral, a building of the middle of the last century on the site of an older one, there are some not very remarkable paintings of Palma Giovine, Bonifacio, and Tintoretto. The town hall has some good frescoes of Pomponio Amalteo in its "loggia," and a curious series of portraits within of the bishops of Ceneda, and another of the *Podestàs*, with the arms of each. The origin of the city, which very numerous finds of urns, inscriptions, coins, lachrymatories, and other objects prove to have existed under the Romans, is uncertain. At the period of the Gothic and Lombard invasions it was a place of some military importance. Alaric fortified it strongly. The Emperor Honorius subsequently gave it with the title of county to one Marcellus. Attila devastated it in 450. The sovereignty of the district was the subject of long contests between the neighbouring counts of Camino and the bishops, with the gradual result of subjecting the city and its district to the republic of Venice, which, however, permitted the bishops and the ancient council of notables to exercise some rights of sovereignty even down to 1776.

It should be added that Ceneda has recently changed its name to Vittorio. This absurd abnegation of its past history has had some little show of reason to excuse it. Ceneda and the neighbouring commune of Serravalle were for many generations hereditary enemies. When the province of Venice was restored to Italy it was determined, among other festive and fraternizing doings, that these two communes should henceforth form but one, to be known as Vittorio,—an appellation which seems to have succeeded in supplanting the old historical name more entirely than usually occurs in similar cases.

CENSOR (from *censere*, to estimate), the title of two magistrates of the highest importance in the Roman republic. It was their duty to take a census of the citizens, to estimate their property and impose taxes in proportion to what each possessed, and to punish offences not only against morality, but against the conventional requirements of Roman custom. They took cognizance of bad cultivation of the land, of the carrying on of any occupation which was considered disgraceful, of luxuriousness, of celibacy, and of many other matters of a similar kind. If the offender was a senator, they might remove him from the senate; if *eques*, they might take from him his horse, they might expel him from his tribe, and they might lower him to ærarian rank. There was, however, an appeal from their decisions to an assembly of the people; and they could only punish a citizen for some definite fault, which they were bound to declare in their list. The censors also appointed the *princeps senatus*, and filled up all vacancies in the senate. At first this was done at their own discretion, but afterwards they were controlled by the *lex Ovinia*, which bound them to choose ex-magistrates in the order of their rank. The censors also let out the taxes to farm; and they took charge of all public buildings, roads, and aqueducts, and undertook the construction of new public works.

At first the duration of the censorship was five years, but in 433 B.C. the dictator Mamercinus made a law

restricting it to a year and a half. Upon the death of either censor the other resigned, and a new election was held. Originally patricians alone were eligible; but in 351 B.C. the plebeians were admitted. The censorship was instituted in 443 B.C.; and the office continued to the time of the emperors. Vespasian and his son took the title; and the last who bore it was the brother of Constantine. The emperor generally assumed censorial power under the title of *morum præfecti*.

CENSUS is now almost solely used to denote that enumeration of the people made at intervals in most European countries, and in the United Kingdom and the British Colonies decennially. The term had its origin in Rome, where a group of the many functions performed by the high officer called censor received the name of *census*. An enumeration of the people was only one of them, but they were chiefly of a statistical character. They were especially directed to fiscal objects; and it does not appear that the enumeration of the people was then deemed of value as a source of statistical knowledge which might influence morals and legislation. It was connected with the Servian constitution, which apportioned the rights and duties of citizens to the amount of property, dividing them into six classes, which were subdivided into centuries by a mixed ratio of wealth and numbers. Had the enumeration been deemed of value for any such other purposes, besides the adjustment of rights and obligations, as those for which statistical knowledge is now deemed so valuable, the notices preserved of the vast collection of statistical facts thus made would have been less scanty and meagre, and we should not have found it so impracticable to come to any conclusion about the population and extent of the city of Rome itself. The Roman census must have been minute and full. It indicated not only the number and respective classes of all free persons, but their domestic position as husbands and wives, fathers and mothers, and sons and daughters. The slaves and freedmen were indicated in connection with the possessions of the head of the house, and landed property was analyzed into several classes according to its character and produce. The important practical effect of the census caused it to be conducted at intervals generally so frequent as every fifth year. It was followed by a sacrifice of purification or lustration, whence the term of five years came to be designated a *lustrum*. There were highly penal consequences to the citizen who neglected his registration for the census, to whom as an unregistered person the name of *incensus* was given. From the mixed functions to which it was applied we have the word used among the Romans to signify the patrimony or property qualification of a particular grade—as *census senatorius* and *census equester*; and we have it employed in later times to indicate taxation. Hence *census dominicatus*, implying a feudal tax to the superior, and *census duplicatus*, a double tax or feudal casualty; and the word *cense*, used by old English writers, was abbreviated in modern use into *cess*.

While the word census was thus applied to the taxation of the Middle Ages, it will readily be understood that in its modern sense it received no practical application, since neither taxation nor the adjustment of social rank required a numbering of the people; and the statistic or economic ends of such a process were as little known as they had been to the Romans. Under the despotic Governments of the Continent, however, the tendency to central organization for purposes of administration and police prepared the way for statistical inquiries into the numbers of the inhabitants of particular areas whenever there should occur an occasion for enumerating them. It was in Britain, with its abstinent Government and unrestrained people, that the want of population statistics became most flagrantly

conspicuous. It is difficult at present to realize the idea that, long after Adam Smith's time, the number of the inhabitants of the British empire could only be guessed at as the populousness of China is at the present day; and, as in all matters of statistics, which have their own simple solution through specific inquiry, the guesses about the population of the empire were not only vague but extravagantly contradictory. During the 18th century, the most trustworthy geographers were generally those who did not venture on an estimate of the population even in those European states which had the best means of enumeration at their command.

The first effort to take a census of the population of Great Britain was made in 1801; it did not then extend to Ireland. The success which attended this and the two succeeding efforts was mainly owing to the zeal and ability of Mr Rickman, the assistant-clerk of the House of Commons. Where there is an organization like that of many in the European states for preserving a constant official record of all the fluctuations of the population, not only in their absolute numbers throughout a whole territory, but in the relative numbers in its respective parts as they may be affected by fluctuations, systematic arrangements are thus prepared not only for obtaining a general census at any one moment, but for checking its accuracy and classifying its elements. But to deal at once with the raw material in the self-governed British empire required great ingenuity and sagacity. A census, to be accurate, must be taken on a uniform system, and must be taken simultaneously. Any enumeration going over a tract of time, were it but two days, must be more or less inaccurate, and destitute of the means of correcting its own inaccuracies. Besides the mere abstract numbers of the people, there is much collateral information to be recorded. This, besides its own intrinsic value, is necessary as a check on the numbers; since a distribution into elements according to sex, age, social condition, occupation, and the like, affords a self-acting control on the accuracy of mere figures. In a census, indeed, it is a simple rule, that the information returned should be extended as far beyond the main facts as with safety to these it can be carried. The tendency towards complexity in the nature of the returns must always be checked by the liability of the people at large to make blunders and create confusion where they are required to attest facts not of the most obvious nature, and by the difficulty of getting a number of subordinate officers to understand and carry out a complex classification. Hence there was great difficulty in obtaining a classification according to occupation, from its complex intermixture with the classification according to families. Thus, in the first census, there was an attempt to classify the people under three divisions—(1) persons chiefly employed in agriculture, (2) persons chiefly employed in trade, manufactures, or handicraft, and (3) all other persons not comprised in the two preceding classes. But Mr Rickman found the returns unsatisfactory, from the difficulty of deciding "whether the females of the family, children, and servants were to be classed as of no occupation, or of the occupation of the adult males of the family." In the two subsequent enumerations, the rule adopted was to record the occupation of the head of the family; but here comes a new element of confusion, in the difficulty of defining the head of a family. Experience, and an anxious desire to combine simplicity and comprehensiveness in the returns, were the only means by which such difficulties could be mitigated.

The enumerations of 1841 and 1851 in England were much facilitated by the uniform system of registration of births, marriages, and deaths which came into operation on 1st July 1837, and which not only afforded the means of

checking the accuracy of the returns, but provided a prompt and skilled machinery accustomed to statistical work. Far more dependence could now be placed on the discretion and skill of the officers to whom the local duties were committed; and the returns were made more minute and complete. In Scotland it was necessary to adopt the method of employing the parish schoolmasters to perform the local duty of enumerating the population in the country districts. In Ireland the first attempt at a general census was made in 1811, but it was decidedly unsuccessful. It was repeated in 1821, but went no further than a bare enumeration of doubtful accuracy. The census taken there in 1831 was subject to correction in 1834, to make it the basis of the new system of national education. In the two subsequent enumerations the aid of the admirable constabulary force, and the use of an ordnance survey, nearly complete in 1841, went far to supply the want of permanent local statistical machinery.

The census of 1851 was taken on the 31st day of March, the previously distributed schedules being then collected. They embraced a return of the local and other conditions of the population during the preceding night.

"At the present census," say the commissioners, "it was resolved to exhibit, not merely the statistics, as before, of parishes, and more completely of parliamentary and municipal boroughs, but also of such other large towns in England and Scotland as appeared for separate mention, and of all the ecclesiastical parishes which, under the provision of various Acts of Parliament, have, during the last forty years, been erected in England and Wales. In addition also to the inquiry concerning the occupation, age, and birthplace of the population, it was determined to ascertain the various relationships (such as husband, wife, son, daughter), the civil condition (as married, unmarried, widower, or widow), and the number of persons blind, deaf, and dumb."

Another novel feature in the census of 1851 was an attempt to supply the statistics of the ecclesiastical and educational condition of the country. It stated the amount of church accommodation at the command of each religious denomination; while a return was procured of those in attendance in the several churches on Sunday, 30th March. The attendance throughout thirty-five religious communities in England on that forenoon was returned as 4,428,338, of which the proportion assigned to the Church of England was 2,371,732. The returns for Scotland, admittedly very imperfect, give a total of 943,951, of which 351,454 belonged to the Established Church. The English report was accompanied by an elaborate history of the several religious communities.

The enumerations in Ireland exhibit statistical novelties of a totally different kind. In 1841 it was resolved, as that country so totally depended on the amount of its agricultural produce, to obtain the statistics of its rural economy. The surface of the country was divided under five heads—arable, plantations, uncultivated, towns, and water; and, with a view to these divisions, a return was made of the character of each farm or other agricultural allotment, with the quantity of live stock and other relevant facts. The attempt was found so successful, that it was renewed with more full effect in 1851, producing 727 tabular folio pages of very valuable information.

Census of 1861.

The enumeration in 1861 was the seventh census of England, and was taken under the superintendence of the Registrar-General, under the powers conferred by three Acts of Parliament, applicable respectively to England, Scotland, and Ireland. By this census it was found that the population of the United Kingdom was 29,321,288, and that of each of the four divisions of the kingdom was as follows:—England and Wales, 20,228,497; Scotland, 3,096,808; Ireland 5,850,309; islands in the British seas, 145,674.

The population of England and Wales, excluding the portion of the army, navy, and merchant seamen abroad, was 20,066,224. The annual rate of increase per cent. of the population in the United Kingdom, in the ten years 1851-61 was 0·55, viz.:—England and Wales, 1·14; Scotland, 0·58; Ireland, (decrease), 1·23; and islands in the British seas, 0·02.

The local machinery by means of which the census of England was taken in 1861 differed in no material respect from that employed in 1851. In subdividing the country the registrars were to see that the enumeration districts were not too extensive or too populous; they were not to contain more than 200 houses in towns, so that they could be enumerated by an active man within the compass of a single day. An important feature consisted of the publication of the number of houses and population in "civil counties" and in lieutenancy subdivisions. The number of blind and of deaf and dumb from birth, the number of foreigners, and the number of naturalized British subjects, were shown in 1861 for the first time. In the case of Scotland, the enumeration was for the first time required to be made apart from that of England, under the superintendence of the Registrar-General of Scotland. From 1855 Scotland had the advantage of a national system of registration, and the census of 1861 was therefore no longer taken through the agency of the sheriffs in counties, and of the provosts or chief magistrates in the royal and parliamentary burghs, but through the agency of 1001 local registrars of births, deaths, and marriages, assisted by 8075 enumerators. The forms and instructions issued were all based on, and in most cases virtually the same as, those used in England in the census of 1851. "Flats" were not reckoned as houses in Scotland in 1861. All the details as to population, &c., in 1851, were for civil parishes and civil counties only. In 1861 the returns were for registration districts and registration counties. The novel features in 1861 for Scotland, which merit special notice, were the number of families in every parish and county, the number of houses having windows, and the number of children between the ages of five and fifteen years in attendance at school. In 1861 it was ascertained that the islands in Scotland amounted to 787 in number, and of these 186 were inhabited by one or more persons on the census day.

The tables in 1861 relating to the ages, conjugal conditions, birthplaces, blind, deaf and dumb, and to the occupations combined with ages, were published uniformly with those in 1851. A comparison can be made of the occupations at the different ages with the death registers, and the comparative mortality prevailing among the different classes and ranks of society can now be ascertained as well as the comparative healthiness of each occupation or trade.

Ireland, 1861.—The enumeration of the people of Ireland in 1861 was effected for the first time altogether (excepting the metropolis) by the officers and men of the constabulary force. The returns show—for provinces, counties, baronies, parishes, towns, and parliamentary boroughs—the area, population, and number of houses, the number of families with their pursuits and the means upon which they were dependent, also the religious professions and education of the inhabitants, the number of families living in each house, and the amount of their accommodation by counties in rural and civic districts, the birthplaces of the people, their condition as to marriage, and their occupations for each county, also tabular summaries relating to vital statistics.

The ages of the people in Ireland were incorrectly returned in 1861, and in the tables of the occupations of the people a large number are left unclassified.

In the Channel Islands and the Isle of Man, the census was taken in conformity with instructions from the Home

Office, by the respective Lieutenant-Governors acting in conjunction with the English central office.

First Imperial Census, 1871.

In 1871 the first *Imperial* census of the British empire was taken, and the population was found to amount to 234,762,593, living upon 7,769,449 square miles of territory; comprising England and Wales, with a population of 22,856,164; Scotland, 3,392,559; Ireland, 5,449,186; islands in the British seas, 147,470; and British Colonies and Possessions (exclusive of the army, navy, and merchant seamen abroad, as they are included in the populations just quoted), 202,917,214. The population of England and Wales, excluding the portion of the army, navy, and merchant seamen abroad, was 22,712,266. The annual rate of increase per cent. of the population in the United Kingdom in the ten years 1861-71 was 0·83, viz.:—in England and Wales, 1·23; Scotland, 0·92; Ireland (decrease), 0·71; islands in the British seas, 0·12.

In this great undertaking the work was subdivided for convenience of execution. In conformity with the Act of Parliament the census of England and Wales was taken by the Registrar-General, assisted by Dr Farr and J. T. Ham-nick. The population was enumerated *in one day* (3d April 1871) by 32,543 enumerators, employed under 2195 registrars and 626 superintendent registrars.

Instructions were issued to the superintendent registrars, and to the registrars of births and deaths, for their guidance in taking the census, and one of the duties requiring their earliest attention was the division of the country into enumeration districts, and just here the registrar had an important duty to fulfil, for he was directed to see that the boundaries of parishes, townships, ecclesiastical districts, municipal and parliamentary cities and boroughs, urban sanitary districts, and all other of the various conflicting and confusing territorial subdivisions of the country, were duly indicated. Most of the registrars laid down the boundaries of their enumeration districts on maps, so as to ensure that no part of their districts was omitted.

These plans of division were first submitted to the various superintendent registrars, and finally to the Registrar-General for approval. The 32,543 enumerators were required to be intelligent, trustworthy, and active, to write well, and to have some knowledge of arithmetic. They were not to be infirm or of weak health, not younger than 18 years, nor older than 65; and they were required to be persons likely to conduct themselves with strict propriety and civility. 627 of the public or charitable institutions were enumerated by the masters or chief resident officers.

In order to facilitate the proper designation of all roads, streets, and houses, a circular was addressed to the mayor of each municipal city and borough, and to the chairman of every local board, suggesting that previous to the census all unnamed roads and streets should be named, and all houses numbered. Circulars were also addressed to the press explaining the objects and uses of the census, so as to aid in securing complete and correct returns.

The enumeration of 1871 was a "*nominal*" census.

The householders' schedules were delivered by the enumerators prior to 3d April. Every separate occupier received a schedule, and this schedule was so prepared in accordance with the 4th section of the Census Act, that, as shown in the annexed example, the name, sex, age, rank, profession or occupation, conjugal condition, relation to head of family, and birthplace of every person who abode in any house, on the night of Sunday, 2d April 1871, might be returned; the blind, deaf and dumb, imbecile, or lunatic were distinguished. At the census of 1871 the numbers of lunatics out of asylums and of imbeciles or idiots were ascertained for the first time.

Name and Surname.	Relation to Head of Family.	Condition.	Sex.	Age (last birthday).	Rank, Profession, or Occupation.	Where born.	If (1) Deaf and Dumb, (2) Blind, (3) Imbecile or Idiot, (4) Lunatic.
1 George Wood.....	Head of Family	Married.....	M	48	(Farmer (of 317 acres, employ- ing 8 labourers and 3 boys))	Surrey, Guildford.....	...
2 Maria Wood.....	Wife.....	Married.....	F	44	Farmer's Wife.....	Scotland.....	...
3 Alan Wood.....	Son.....	Unmarried.....	M	29	Farmer's Son.....	Surrey, Guildford.....	...
4 Flora Jane Wood.....	Daughter.....	...	F	12	Scholar.....	Kent, Ramsgate.....	...
5 Ellen Wood.....	Mother.....	Widow.....	F	71	Annuitant.....	Canada.....	Lunatic.
6 Eliza Edwards.....	Servant.....	Unmarried.....	F	24	General servant (domestic).....	Middlesex, Paddington.....	...
7 Ann Young.....	Servant.....	Unmarried.....	F	22	Dairymaid.....	Surrey, Croydon.....	...
8 Thomas Jones.....	Servant.....	Unmarried.....	M	21	Farm Servant.....	Essex, Epping.....	...

The despatch of forms and instructions began as soon as the office in Craig's Court was opened, and included 6,500,000 householders' schedules, weighing about 41 tons. The enumeration books and forms sent out weighed in the aggregate about 54 tons. But in addition to these there were sent out from the central office no less than 115 different descriptions of printed instructions, forms, and circulars, including a calendar, so that certain operations might be summarized.

The metropolitan, the municipal, and the county police afforded help in enumerating the houseless population. The strength of the navy, in forms prepared for the purpose, was returned by the Admiralty; the merchant seamen, in port or out at sea, by Her Majesty's Customs, and by the Registrar-General of merchant seamen; and His Royal Highness the Field-Marshal Commanding-in-chief supplied full returns of the various particulars respecting the army. The numbers of British subjects in foreign states and in India and the population of the Colonies were obtained through Her Majesty's Secretaries of State for Foreign Affairs, India, and the Colonies.

Welsh schedules were issued for the use of a certain number of the Welsh people, and it was found that in 17,276 of these the particulars were inserted in the Welsh language, and had to be translated.

The enumerators were instructed to consider a house as comprising all the space within the external and party walls of a building, whether occupied by only one family, or by several families living in distinct stories or apartments; and they were also instructed, when delivering their schedules, to make a record, in a "memorandum book" supplied for the purpose, of the road or street in which every house was situated, and of the name or number of each house, and to state the number of schedules left at each house. Uninhabited houses, houses building, churches, chapels, and all other public buildings were likewise noticed in this book. With the assistance of the police, the enumerator had to make or procure returns of all persons not dwelling in houses, but sleeping in barns, sheds, caravans, or tents, or in the open air.

Special schedules were printed for the enumeration of persons in public institutions, on board vessels, or in charge of boats and barges employed in inland navigation.

Persons travelling during the night of Sunday, 2d April, were to be included in the schedule of the proprietor or manager of the hotel or inn, or in the schedule of the occupier of the house, at which they arrived on the morning of Monday, 3d April. Persons engaged in work away from home during the night of Sunday, 2d April, were to be included in schedules left at their houses.

The cause of an unusual number of persons being temporarily absent or present was to be noted.

When the enumerators had collected and arranged their schedules, they were copied into enumeration books provided for this purpose, and a summary was made of the population of each civil parish, township, or place, and these books were delivered to the registrar on or before 10th April, by whom they were examined and corrected, and forwarded on or before 24th April to the superintendent registrar.

The enumeration books were then revised by the

superintendent registrar, who was at this stage required to fill up a printed form, showing a summary of the houses and population in each sub-district, municipal or parliamentary city or borough, &c., and transmit the whole to the Census Office in Craig's Court.

On receipt of the books and summaries by the Registrar-General, the abstract required by the 9th section of the Census Act was prepared and laid before Parliament on 20th June 1871.

As soon as the preliminary report, consisting of 137 pages, was published, the work commenced at the central office of revising the enumeration books so as to ascertain the correct number of houses and population in each of the various subdivisions of the country, and in order to ensure accuracy in the preparation of this work, statements of the houses and population of ecclesiastical districts and other local subdivisions were submitted to the clergy and to the various local authorities for approval. The registrars were required to state the cause of any remarkable increase or decrease of population, and a proof of the tables relating to each county was submitted to the clerk of the peace for correction and approval.

The abstracts relating to the occupations and ages of the people were a great work. It was considered desirable not only to take out the number of persons of each sex in each occupation, but the number at each quinquennial period of age; for without this information the relative salubrity of the professions, and a great variety of other important questions could not be determined.

In this arrangement of the people according to occupations and ages, they had not only to be classified in different orders, but it was necessary to find a place for every one of the 23 millions of population, so as to be enabled to pass them rapidly and distinctly in review.

The classification of the living according to their professions and occupations in combination with age has opened up a new field of inquiry, and the question can now be determined for sanitary purposes, and for life insurance, what effects the different professions and occupations have on health at different ages. Formerly, the mean age at death was taken to show the healthiness or insalubrity of certain occupations. But the mean age at death depends upon many circumstances besides health, and among others, upon the ages of the living, which vary in proportions in almost every profession, according as it is a profession that people enter early or later in life. Insurance offices and friendly societies will find the results of the third volume of the Census of England in 1871—in conjunction with the 14th Annual Report, and the two Supplements to the 25th and 35th Annual Reports of the Registrar-General, recording the mortality of persons at different occupations—of great use to them in their transactions, for it is evident that the lives of farmers, for example, may be safely insured at much lower rates than the lives of licensed victuallers.

Many important results for "civil counties" were published in 1871 that will not be found in the census returns of 1861, such as a description of the territorial, executive, and ecclesiastical divisions in each county, more exact areas from the ordnance survey, additional columns showing

the houses under three headings, and distinguishing the sexes of the population, additional columns showing area, number of electors, and of members within the parliamentary limits, including and excluding represented boroughs, petty sessional divisions, wards of municipal boroughs, comparative tables of houses and population in 1861 and 1871, tables showing the number of families in each civil parish and township, and results showing the residue of area and population in mother parishes.

Also under "registration counties" many new particulars were published in 1871, such as maps of counties and districts, showing the population of large towns, and the particulars as to reformatory and industrial schools, and as to Her Majesty's ships.

The census of Ireland in 1871 was taken by the Registrar-General of Ireland, assisted by two other commissioners, W. R. Wilde and G. W. Abraham. The enumeration (except in the metropolis, in which 178 of the Dublin Metropolitan Police discharged that duty) was effected by 4536 members of the Royal Irish Constabulary, whose local knowledge and previous experience as enumerators on three former occasions rendered them peculiarly well suited for this undertaking. The country was divided into 248 districts, each under the charge of a sub-inspector. Printed instructions were furnished, and, when necessary, the enumerators were supplied with maps, conveyances, boats, and in the Irish-speaking districts with interpreters also. In conformity with the Census Act an abstract of the census of Ireland was published on 14th June 1871, showing the number of houses, families, and population in each county and city, and in certain corporate towns in Ireland. The numbers in the different religious professions were also returned as directed by the Act. The revised and final numbers for Ireland record the population in 1871 at 5,412,377, showing a decrease since 1861 of 386,590 or 6·67 per cent. In the previous decenniad, 1851-61, the population had decreased by 753,418, or 11·50 per cent. The decrease in the population of 1871 is stated to be chiefly attributable to emigration. From 1st May 1851 to 31st March 1871 the loss by emigration amounted to 2,024,609. Results relating to the ages, civil conditions, occupations, birth-places, religion and education of the people are published in the census returns for Ireland; and instructions were issued by the Government, directing that the results of the census of 1871 for each of the three divisions of the kingdom should be published, with a view to uniformity. Some of the principal results have thus been assimilated in 1871, but there is still a considerable want of uniformity, especially as regards the ages of children in Ireland. A volume devoted entirely to vital statistics is not the least interesting of the results of the census of Ireland in 1871.

As regards Scotland, the results of the census of 1871 are nearly uniform with those of England. In addition to the ordinary particulars, inquiries were made as to the number of children from five to thirteen years of age receiving education, and the number of rooms with windows. This census was taken by the Registrar-General of Scotland and Dr Stark, through the agency of 1016 local registrars, assisted by 8342 enumerators, whose appointments were approved by the sheriffs in counties, and by the chief magistrates in boroughs. The returns for Scotland in 1871 contain some new features, such as the ecclesiastical subdivisions of civil counties, grouping the population of each civil county into three great divisions, according as they inhabited towns, villages, or rural parts; the particulars as to houses, families, and population relative to parliamentary constituencies of counties are also new. As there were no registration districts in 1851, no attempt was made in 1861 to show the relative increase or decrease of the

population from 1851. But in the census of 1871, this want was supplied by giving the number of the population in each district for 1861, for comparison with that of 1871. The number of children from five to thirteen years of age in the receipt of education also appears for the first time in the returns for 1871.

The census of the Island of Man and of the Channel Islands was taken by the lieutenant-governors according to directions issued by the Secretary of State for the Home Department, but the forms and instructions were issued by the Registrar-General of England. The population of these islands on the aggregate in 1871 was 144,638, viz.:—Isle of Man 54,042, Jersey 56,627, and Guernsey and adjacent islands 33,969.—No census of the Isle of Man was taken earlier than that of 1821, when 40,081 persons were enumerated. Enumerations of the inhabitants of Jersey were made in 1806 and in 1815, in which years the population was respectively returned as 22,855 and 22,763. The first census of Guernsey, &c., was taken in 1821, and was 20,302. The population of these islands has remained nearly stationary at the last three censuses.

The cost of the census, incurred at the central office, and in payment of local officers in each of the three countries in 1871, was £5, 5s. 7½d. per 1000 of the population for England and Wales, £8, 1s. 4d. for Scotland, and £7, 2s. 7d. for Ireland.

The results of the census of 1871 are multitudinous, and it is impossible here to enumerate all the facts of interest which the returns disclose. Those relating to parliamentary constituencies show that of 95 counties, or divisions of counties, the population had increased since 1861 in 82, while in 13 the population had decreased. Out of 198 boroughs which returned members to Parliament the population had increased in 156, while in 31 the population had decreased. In the year 1868 the boundaries of 68 boroughs were altered, and in some of these the increase of population may be due to enlarged area. Eleven boroughs had been formed since 1861. Some of the elaborate results afford the means of solving important questions relating to the industrial organization of the country, and show to what extent there has been a diminution in the numbers employed in the cultivation of the soil, and to what extent there has been a consolidation of farms, affecting the average size of the holdings. Other results show the ages of the married and unmarried population, and these, combined with the returns of the ages at marriage, furnish the means of determining very important questions, such as the probable duration of the joint lives of husband and wife, the annual rate of marriage at different ages, and so on. Tables showing the number of foreigners resident in England and Wales, and the number of British residents abroad, throw much light on many points relating to the social condition of the people. Not the least useful of the results is an interpolated table of the population at each year of age, furnishing school-boards with the means of ascertaining the proportional number of children at the school ages, and enabling life insurance offices and scientific and other authorities to solve many important problems. (W. F.)

Census of the United States.

The census in the United States is a political necessity. To this, and not to the general appreciation of the claims of statistical science is due the fact that the systematic periodical enumeration of inhabitants was there undertaken earlier even than in England.

Had the government set up in 1787 been a pure confederation, like that which preceded it, into which the States entered as equal bodies, the census would not have been a condition of its existence; while rude estimates

founded on the number of the natural militia, the arms-bearing population, or on the number of horses, or on the records of births and deaths, might long have answered all administrative purposes. On the other hand, had the Constitution of 1787 erected a single, self-sufficient government, a simple sovereignty, the census need not have been provided for in that instrument. Representative power might have been apportioned approximately according to common fame, or numbers might have been rejected as the measure of political power, as in England, and even as in Connecticut, alone of all the States of the American Union, to-day.

But the mixed form of government established by that constitution, the only form of government which was then possible, by which the pre-existing States maintained their right to exist and to act for themselves in all strictly internal affairs, while for all national purposes political power was to be exercised by a double rule, partly through the States acting as equal bodies, and partly according to population irrespective of State lines, positively required, not as a means of administrative efficiency, but as an essential condition of its own existence, that the inhabitants of the United States should be periodically enumerated. Accordingly, we find in the Constitution of 1787 a provision for a census to be taken every ten years, the first enumeration to be made "within three years after the first meeting of the Congress of the United States."

It would appear from this brief review that the eulogium of Moreau de Jonnés was scarcely merited, when he declared that the United States present a phenomenon without parallel in history,—“that of a people who instituted the statistics of their country on the very day when they founded their government, and who regulated by the same instrument the census of inhabitants, their civil and political rights, and the destinies of the nation.” As a matter of undoubted history, the provision for a national census was incorporated in the constitution solely from political, not at all from philosophical, considerations. Pending the actual accomplishment of the first enumeration, an estimate of the population of the several States was adopted as a provisional basis of representation in Congress.

The first census was taken in 1790, the returns all being referred to the 1st of August of that year, although the work of canvassing was extended over a considerable period. As was the case with the first British census eleven years later, and as is likely to be the case with the first census of any community, great disappointment was felt at the result, and dissatisfaction at the methods of enumeration was loudly expressed. Mr Jefferson, then Secretary of State, was careful in sending abroad copies of the published tables, to impress it on the minds of his correspondents that the returns fell far short of the truth, and even went so far as to supply the omissions which he assumed to exist. The results of later censuses, however, have established the substantial accuracy of the first enumeration, and shown that the dissatisfaction felt at the time was but the inevitable disappointment of over-strained anticipations. “To count,” says Dr Johnson, “is a modern practice; the ancient method was to guess; and where numbers are guessed, they are always magnified.” General censuses were taken in 1800, 1810, and 1820, with exact intervals of ten years. In 1830 the date of enumeration was fixed on the 1st of June. This change made the interval between the fourth and fifth censuses nine years and ten months only, reducing the nominal ratio of increase between 1820 and 1830, by about two-thirds of 1 per cent. The succession of census was then resumed with exact intervals of ten years. The ninth census was taken as of date June 1, 1870.

Peculiarities of the Constitution of the United States have been spoken of which rendered the census a political necessity, and secured its adoption there earlier than in countries far more advanced in statistical science and in the arts of administration. To the same peculiarities are attributable the features by which the census of the United States has come to differ from the census of other countries. The reservation by the States of all rights not granted to the general Government makes it fairly a matter of question whether purely statistical inquiries, other than for the single purpose of apportioning representation, could be initiated by any other authority than that of the States themselves. That large party which advocates a strict and jealous construction of the constitution would certainly oppose any independent legislation by the national Congress for providing a registration of births, marriages, and deaths, or for obtaining social and industrial statistics, whether for the satisfaction of the publicist, or for the guidance of the legislature. Even though the supreme court should decide such legislation to be within the grant of powers to the general Government, the distrust and opposition, on constitutional grounds, of so large a portion of the people, could not but go far to defeat the object sought.

In this political difficulty, the unquestionable provision of the constitution for a decennial census has been taken advantage of by all parties to secure much statistical information, which is not usually, and perhaps is not properly, connected with a census. Nor can there be any doubt that the introduction of new schedules of inquiries has, since 1850, somewhat impaired the efficiency of the census in its original constitutional function of making a count of the inhabitants of the several parts of the country for the purpose of distributing representation in Congress. As the census has widened, it has weakened. More has been put upon the enumerator than he could well carry. His attention has been distracted by the multiplicity of objects presented; the great number of inquiries has also perplexed and irritated the body of citizens; while the result of protracting the canvass to obtain additional information has, in the incessant changes of population, especially in cities and in manufacturing villages, allowed not a few to escape enumeration altogether.

The first enlargement of the scope of the census was in 1810, when the agents of the census were by law required to take an account of the several manufacturing establishments and manufactories within their several districts. The same requirement was contained in the Act for the census of 1820; but the results proved of so little value that the attempt was altogether abandoned in 1830. In 1840 a manufacturers' schedule was used, and inquiries respecting schools were incorporated. It was at the seventh census, 1850, however, that the main enlargement was effected. By the Act of May 23 of that year, the census was extended to cover the several subjects of mortality, agriculture, productive industry, schools, churches, newspapers, &c., &c.

The agencies and methods of enumeration in the census of the United States have been but little changed from the first, and are to-day antiquated and ineffective in a high degree. By the Act of 1790, it was made the duty of the marshals of the United States courts in the several judicial districts to take the enumeration, appointing therefor as many assistants as they should deem necessary. The enumeration was to commence August 1, and to close within nine calendar months thereafter; the returns were to be filed with the clerks of the several courts, while the marshals were to forward to the president “the aggregate amount of each description of persons within their respective districts.” In 1800 the supervision of the census was placed with the Secretary of State. The

machinery or enumeration remained until 1850 the same as in 1790.

In 1810 the agents of the census were placed under the direction of the Secretary of the Treasury as to the enumeration of manufactures required; but in 1820 the entire charge remained with the Secretary of State. In 1850, the supervision of the census was committed to the newly created Department of the Interior, and the period allowed for enumeration was restricted to five months. As a matter of fact, no enumeration has been completed within that time. The United States marshals and their assistants remained the agents of the census office; and a superintendent of census was appointed. In preparation for the census of 1870, a committee of the House of Representatives, under the chairmanship of General James A. Garfield of Ohio, presented a bill which sought to bring the census as nearly up to the demands of modern statistical science as the peculiar conditions of settlement and occupation in the United States would allow. The report of the committee dwelt strongly on the essential viciousness of a protracted enumeration, and on the general unfitness of the marshals of the courts to perform the duty. The bill, however, did not propose a single-day enumeration, but allowed a month for its completion. The schedules of inquiries were largely increased in recognition of the impossibility of obtaining statistical information under authority of the United States Government, except under cover of the constitutional provision for a decennial census. The rank and power of the superintendent of census were increased.

The bill of the committee was carried through the House of Representatives by large majorities, but failed in the Senate. The census of 1870 was consequently taken under the Act of 1850 with two or three inconsiderable amendments.

The cost of each census has been as follows:—

	Dollars.		Dollars.
1790.....	44,377	1840.....	833,371
1800.....	66,609	1850.....	1,318,028
1810.....	178,445	1860.....	1,917,540
1820.....	208,526	1870.....	3,360,884
1830.....	378,543		

In the census of 1870 the work of enumeration was performed by 6572 assistant marshals, supervised by 61 marshals of United States courts.

Prior schedules so called, that is, schedules to be left at the residence in advance of the enumeration, to be filled up by the head of the family, have never been used in a census of the United States, though adopted in nearly every European country.

(F. A. W.)

CENTAURS (*Kένταυροι*), in Greek mythology, were beings part horse part man, i.e., a horse had its neck and head replaced by the head and body of a man down to the waist. The oldest form was that of a man altogether in front with the body and hind legs of a horse attached to his back. In peopling solitary and wild places with imaginary beings it was usual to assign to these beings a bodily form in some obvious way consistent with the features of the locality; thus, Pan, the spirit of rocky hills, was imagined as having goat's legs, and Scylla, the spirit of sea-storms, as having the body and tail of a fish. In most cases the animal adjunct was made to supersede the human legs, as if the first consideration had been that the spirit should have a non-human means of locomotion. In the case of the Centaurs whose home was in mountainous and wooded regions with wild torrents, chiefly in Thessaly and Arcadia, the horse may have been chosen either as symbolic of the impetuosity of streams and winds, or from the circumstance of such districts being favourable for horse rearing. One of the Centaurs, Chiron, who lived in a cave on Mount Pelion, was a friend of gods and heroes, skilled in medicine and music, and as an instructor of

youth; but as a race they were best known for their battle with the Lapithæ, which arose at the marriage of Peirithous and Deidamia, when the Centaurs, excited with wine, attempted to carry off the bride, but were overpowered by the help of Theseus, who was present; hence this subject, generally suitable for sculpture, was a favourite with Athenian artists. The Centaurs formed part of the retinue of Bacchus. No satisfactory derivation of the name has yet been given.

CENTIPEDES and MILLEPEDES, the popular names of the two orders of Articulate animals which until lately formed the entire class *Myriapoda*. They were formerly classed with insects, which they resemble in their jointed limbs and antennæ, and in their respiratory system, but they have also points of contact with annelid worms, with crustaceans; and with spiders, by which they are marked as a transition group, intermediate between the lower and higher Articulate. Myriapods (*μυριάς*, ten thousand, and *πούς*, a foot) are elongated worm-like creatures, cylindrical or flattened, and composed of numerous segments, each bearing one or two pairs of jointed legs,—those on the anterior segments being modified, as in the Crustacea, so as to form the organs of the mouth. The fang-like, prehensile jaws of the centipede, perforated at their extremities to allow of the passage of the liquid venom into the wound they have inflicted, are thus simply modifications of a pair of legs. The eyes consist of a number of *ocelli*, congregated together on the head, and, with a single exception, are never compound, as in insects. Like the latter, they breathe by means of tracheal tubes, opening by stigmata placed on both sides, behind the insertion of the legs, and kept permanently open by a spiral chitinous fibre. They are unisexual, the organs of generation being, however, differently placed in the two groups, occurring anteriorly in millepedes, and posteriorly in centipedes. The young of many species closely resemble their parents from the time they leave the egg, only with fewer limbs and segments; these, however, increase with each successive moulting until the normal number of the adult is reached. Other species, as those of the family *Julidæ*, undergo, during their period of growth, modifications closely resembling the metamorphoses of insects. Their larvæ at first either are destitute of legs, or have only three pairs situated anteriorly; and it is only after a long series of moultings, extending in some cases over two years, that their maturity is signalized by the appearance of sexual organs.

Myriapods have been usually divided into the two orders *Chilognatha* or Millepedes and *Chilopoda* or Centipedes; but recently a small myriapod, $\frac{1}{16}$ th of an inch in length, was discovered by Sir J. Lubbock, among decomposing vegetable matter, differing from the other members of the class in the absence of tracheæ, apparently absorbing air through its semi-transparent skin, in the smaller number of its legs (nine pairs), and in the bifid character of its antennæ; and this has been made the type of a third order—*Pauropoda*. *Pauropus Huxleyi* Lubbock describes as an active, cleanly little creature, with a look of cheerful intelligence, in marked contrast to the dull stupidity of the *Julidæ*, or the melancholy ferocity of the centipede. Millepedes, or "Thousand-Legs," are readily distinguished from the other group by their antennæ, which are always six or seven jointed, by the generally cylindrical shape of the body, and by the possession of two pairs of legs on each segment—the last posterior segments and a few anterior excepted. Each segment also bears a pair of stigmata or tracheal openings, instead of every alternate one, as in centipedes; and this fact, taken in connection with the double quantity of legs, has led to the belief that each segment in the millepede has been formed by the union of two, a view further strengthened by the presence of a

distinct transverse groove down the centre of each. The legs of millepedes though numerous are exceedingly weak, and in moving they appear to glide along like footless worms. They are most frequently found among damp moss, and beneath masses of decaying vegetable matter on which they feed; and when in danger they roll themselves into a ball. The British species are few, and the largest of these does not exceed 2 inches in length; but there is an American form which attains a length of 8 inches. All are equally harmless, the prehensile jaws being rudimentary, while the other parts of the mouth are modified to suit their purely vegetable diet.

Centipedes, or "Hundred-Legs," have their segments flattened, and covered with a leathery skin, and have one pair of legs on each segment, the posterior pair being directed backwards and elongated so as to resemble a couple of jointed tails. Their antennæ have not less than fourteen and rarely more than forty joints, while the body segments do not usually exceed twenty. The organs of the mouth are masticatory, and are admirably adapted to the carnivorous habits of the centipede. It feeds principally on insects, seizing them with its powerful prehensile organs, and injecting at the same time its venom into the wound. The bite of the larger forms, as *Scolopendra morsitans*, occurring in tropical countries, is exceedingly painful, and is described by those who have suffered from it "as similar to what might be produced by contact with a red-hot iron," giving rise to swelling, throbbing pains, and febrile symptoms (Dr Collingwood's *Naturalist's Rambles in the China Seas*). These, however, yield readily to an application of ammonia. Centipedes seldom exceed a foot in length. They are exceedingly active in pursuit of their prey, insinuating their many-jointed and flattened bodies under stones, beneath the bark of trees, and wherever insects usually lurk. *Lithobius forcipatus*, the commonest British species, is 2 inches long, and quite harmless, although when seized it attempts to fix its jaws into the skin of its captor. The species belonging to the genus *Geophilus* are said to be luminous in the dark. Upwards of twenty species of fossil Myriapoda are known,—the oldest from the Coal Measures of North America, and belonging to the millepede or vegetable-eating division. One of these, *Xylobius sigillaria*, was found in the hollow trunks of the fossil *Sigillaria*.

CENTLIVRE, SUSANNA (1667–1723), a dramatic writer, was born in 1667, or perhaps a year or two later, probably in Ireland, whither her father, Mr Freeman, a Lincolnshire gentleman, had been forced to flee at the Restoration on account of his Parliamentary principles. Being left an orphan about the age of eleven she came to London, where, at the age of sixteen she married a nephew of Sir Stephen Fox. About twelve months afterwards her husband died; and she then married a military officer named Carrol. Carrol was killed in a duel about a year and a half after their marriage, and his widow was left to support herself by her pen and by acting. Her first attempt was a tragedy called the *Perjured Husband*; but almost all her subsequent pieces were comedies, several of which, through their liveliness, enjoyed very considerable popularity, as for example the well-known *Busbody* (which has been represented within the last few years), *A Bold Stroke for a Wife*, *The Basset-table*, *The Wonder—A Woman keeps a Secret*, *Love at a Venture*. Her wit and personal attractions also gained her the support of Steele, Farquhar, Rowe, and many others of high position in literature and society. In 1706 she married Mr Joseph Centlivre, principal cook to Queen Anne, with whom she lived till her death in 1723. Her dramatic works were published, with a biography, in 3 vols. 12mo, 1761, reprinted 1872.

CENTO, a town of Italy, in the province of Ferrara, 16 miles north by west of Bologna, situated in a fertile plain near the Reno. It is the seat of a bishop, has a cathedral and several fine buildings, and carries on a trade in grain and hemp; but it is chiefly remarkable as the birthplace of the painter Guercino, several of whose works are to be seen in the churches of St Biagio and the Madonna del Rosario. His house is still preserved, and a statue has been erected to his memory in the middle of the town. Population about 19,000.

CENTO (Greek κέντρον, Latin *cento*, patchwork), a composition made up of passages from other works. The Byzantine Greeks manufactured several out of the poems of Homer, among which may be mentioned the life of Christ by the famous Empress Eudoxia, and a version of the Biblical history of Eden and the Fall. The Romans of the later empire and the monks of the Middle Ages were fond of constructing poems out of the verse of Virgil. Such were the ancient *Cento Nuptialis* of Ausonius, the sketch of Biblical history which was compiled in the 4th century by Proba Falconia, wife of a Roman proconsul, and the hymns in honour of St Quirinus taken from Virgil and Horace by Metellus, a monk of Tegernsee, in the latter half of the 12th century. Specimens may be found in the work of Aldus Manutius (Venice, 1504; Frankfurt, 1541, 1544). In 1535 Lælius Capitolinus produced from Virgil an attack upon the dissolute lives of the monks; in 1536 there appeared at Venice a *Petrarca Spirituale*; and in 1634 Alexander Ross (a Scotchman, and one of the chaplains of Charles I.) published a *Virgilius Evangelizans, seu Historia Domini nostri Jesu Christi Virgilianis verbis et versibus descripta*.

CENTORBI, or CENTURIBE, the ancient *Centuripa*, a town of Sicily, on a rugged mountain, in the province of Catania, and 20 miles W.N.W. of the city of that name. At a very early period Centuripa was an important town of the Siculi; and through various vicissitudes it succeeded in maintaining its independence until the first Punic war, when it was besieged by the consuls Otacilius and Valerius Messala. In the time of Cicero it was one of the most flourishing places in the island, and had a population of about 10,000. In 1233 it was destroyed by Frederick II. Extensive remains of the ancient city still exist. The new town has a population of upwards of 7000.

CENTRAL AMERICA, as a geographical division, would naturally include the whole stretch of territory from the Isthmus of Tehuantepec to the Isthmus of Darien, which forms the nexus between the two great masses of North and South America; but political arrangements have so affected the use of the name that it only includes the portion corresponding to the five independent North American republics of Costa Rica, Nicaragua, Honduras, San Salvador, and Guatemala, while the Isthmus of Panama is assigned to South America as a part of New Granada, and the Isthmus of Tehuantepec and the Peninsula of Yucatan are incorporated with North America as parts of Mexico. Central America thus lies between 7° and 18° of N. lat., extends about 800 or 900 miles in length, and has a varying breadth of from 30 to 300 miles. For details the reader is referred to separate articles on the five republics mentioned above, which formed a federal republic from 1823 to 1839, and have frequently endeavoured since then to effect a restoration of their union.

CENTRAL INDIA POLITICAL AGENCY, the official name for a group of feudatory states in the middle of India. Roughly speaking, they are bounded on the N. by Rájputaná, the North-Western Provinces, and Oudh; on the E. by the Chhotá Nágpur division of Bengal, or the S. by the Central Provinces, and on the W. by Bombay. The total area of these states is not accurately known,

but is probably not less than 90,000 square miles, and the population is computed at over 8,000,000 souls. The individual states which make the group have nothing in common with one another, apart from the diplomatic link which connects them all with the British power through the person of the agent to the Governor-General. The principal of the feudatories are Gwalior (Seindiah), Indor (Holkar), Rewah, and Bhopal. Each of these states will be found noticed in its respective place in alphabetical order. The total number of states, great and small, comprising the Central India Political Agency is 71.

CENTRAL PROVINCES, a Chief-Commissionership of British India, situated between 17° 50' and 24° 30' N. lat., and between 76° and 85° E. long., comprising an area of 81,078 square miles, and a population returned by the census of 1872 at 8,201,519. The Chief-Commissionership was constituted in 1861, when the territories previously known as the Nagpur Province and the Sagar and Nerbudda Territories were united under the name of the Central Provinces. This large tract, comprising almost every variety of soil and of physical aspect, and inhabited by races of very diverse origin, is bounded on the N. by the feudatory state of Rewah, by the small native states of Bundelkhand, and by the district of Lalatpur in the North-Western Provinces; on the N. and E. by the Chhotá Nagpur division, the Orissa tributary states, and the northern districts of Madras; on the S. by the Godavari district; and on the S.W., W., and N.W. by the Nizam's dominions, the Berar districts, and the states comprising the Central India Agency. The Central Provinces are divided into four divisions or commissionerships,—Nagpur, Jabalpur, Nerbudda, and Chhatisgarh, comprising 19 British districts. Two districts, Sagar and Damoh, lie parallel to each other upon the Vindhyan table-land. To the south of them, in the valley of the Nerbudda and its tributaries, are the districts of Mandla, Jabalpur, Narsimhpur, Hoshangabad, and a part of Nimar, the rest of it being in the valley of the Tapti. The next range of districts continuing southwards includes Betul, Chhindwara, Seoni, and Balaghat, occupying the Satpura table-land, and attaining a height of about 2000 feet. Still further to the south is the great Nagpur plain, formed by the valleys of the Wardha and Wainganga, and comprising the districts of Nagpur, Wardha, Bhandara, and Chandia. To the east is the Chhatisgarh plain, a low plateau of red soil, containing the districts of Raipur, Bilaspur, and Sambalpur. Last of all, in the extreme south, and almost cut off by forests and wild semi-independent states, is a long strip of territory lining the left bank of the Godavari, and known as the Upper Godavari district.

Physical Geography and Scenery.—The official compiler of the statistical account of the Central Provinces thus describes the physical aspects of the country:—"Within comparatively narrow limits, a plateau and a plain follow each other, and again, in similar sequence, a larger plateau and a larger plain, ending in a mass of hill and forest, which is probably the wildest part of the whole Indian peninsula. Even the continuously level portions of this area are broken by isolated peaks and straggling hill ranges; while its rugged formation and rapid slopes give to the greatest rivers which rise in it, such as the Nerbudda and Tapti, something of the character of mountain torrents. Though the scenery is on too small a scale to compare in sublimity with that of the Himalayas, it is on the other hand as far removed from the monotony of the plains of Hindustan. Not only is it characterized by a constant variety of form and level, but it possesses a diversity of colour peculiar to itself. In no other part of India are the changes of soil and vegetation more rapid and marked than in the Nerbudda country. In the pleasant winter months, the eye may

range over miles of green corn lands, only broken by low, black, boundary ridges or dark twisting footpaths. The horizon is bounded here and there by hill ranges, which seem to rise abruptly from the plains, but on coming nearer to them, the heavy green of their slopes is found to be divided from the softer hues of the young wheat by broad belts of gravelly soil studded with fine trees. On the Satpura plateau the alternations of scenery are even more frequent than in the low country. The hills are higher and more abrupt, the black soil deposits are deeper, and the water supply more abundant. Hence in the midst of the grim rolling plateaus of basalt, there may often be found little valleys cultivated like gardens,—oases of sugar-cane and opium, which, but for their inaccessibility, would tempt away the best cultivators of the plains. It is thought that in some of these upland basins, tea, coffee, and other delicate plants might be raised with success, but the obstacles which have so long retarded the settlement of these plateaus, though partially smoothed away, still exist, and can only be surmounted by patient and continued energy. Much has been done to open out the country of late years. Railways from both coasts now connect the plateau with the eastern and western seaboard, and form the central link of communication between Calcutta and Bombay."

The principal rivers of the Central Provinces are the Nerbudda, Tapti, Wardha, and Wainganga, but, owing to falls and rocky rapids, they are navigable only at certain times of the year and for short distances. As a means of communication they are practically useless. The chief lines of road are the following:—

(1) From Jabalpur to Sagar *via* Damoh, 116 miles; (2) from Jabalpur to Raipur *via* Mandla, 203 miles; (3) from Sagar to Kailash on the Great Indian Peninsular Railway, 76 miles; (4) from Narsimhpur to Chhindwara, 91 miles; (5) from Hoshangabad to Betul, 68½ miles; (6) from Nagpur to Raipur, 174 miles; (7) from Nagpur to Chhindwara, 78 miles; (8) from Nagpur to Betul, 104½ miles; (9) from Nagpur to Chandia, 96 miles; (10) from Raipur to Sambalpur, 167 miles; (11) from Chandia to Sironcha, 121 miles.

The country is intersected by the Great Indian Peninsular and East Indian Railways. The Great Indian Peninsular Railway from Bombay enters the Central Provinces near Barhanpur, and runs north-east to Jabalpur, where it joins the East India line from Allahabad and Calcutta. A branch of the Great Indian Peninsular Railway, which leaves the main line at Bhasawal in Kaudesh, enters the Central Provinces at Wardha, and runs to Nagpur. A state line is in course of construction to connect this railway with the newly-opened coal-fields of Chandia.

The population of the 19 districts of the Central Provinces was returned by the census of 1872 at 8,201,519, made up as follows:—Hindus 5,879,950, or 71·69 per cent. of the total population; Muhammadans, 233,247, or 2·81 per cent.; Buddhists and Jains, 36,569, or 0·45 per cent.; Christians, 10,477, or 0·13 per cent.; and "others" (consisting chiefly of Gonds and the original inhabitants of the country before they were driven back by their Hindu conquerors), 2,041,276, or 24·89 per cent. The census report of 1872 returns 39 towns containing upwards of 5000 inhabitants. Of these 26 have less than 10,000 inhabitants; 5 between 10,000 and 15,000; 3 between 15,000 and 20,000; 3 (Burhanpur, Sagar, and Kamthi) between 20,000 and 50,000; and only 2 (Nagpur and Jabalpur) over 50,000, the former having a population of 84,441, and the latter of 55,188.

Of the total surveyed and assessed area of the British territory 12,352,473 acres were returned in 1873-74 as actually under cultivation, 12,220,845 acres as cultivable but not under tillage, 1,365,071 acres as grazing lands, and 10,885,296 as uncultivable waste. Wheat, rice, and cotton are the principal agricultural staples. The recently-discovered coal-fields and iron-beds in the Wardha Valley

and the Chándá district promise to open a new era of prosperity for the country.

The improved means of communication afforded by the railways and roads have rapidly developed the trade of the Central Provinces. In 1863-64 the imports and exports were valued at about four millions sterling. In 1868-69 their value had risen to six and three-quarter millions sterling. In 1873-74 the ascertained imports of the Central Provinces amounted to 117,761 tons, value £4,399,134, and the exports to 209,157 tons, value £3,148,598; total of imports and exports 326,918 tons, value £7,547,732.

Administration.—The executive authority at Nagpur vests in the chief-commissioner and agent to the Governor-General. He is assisted by a secretary and staff, a judicial commissioner, a settlement commissioner, a sanitary commissioner, a commissioner of customs, four commissioners of revenue and circuit, an inspector-general of police, an inspector-general of public instruction, an inspector-general of jails and dispensaries, a conservator of forests, and a registrar-general of assurances, who is also commissioner of excise and superintendent of stamps. A commissioner presides over each of the four divisions, with a deputy-commissioner and assistants in each of the nineteen districts, all subordinate to the chief-commissioner at Nagpur. The total revenue of the Central Provinces in 1873-74 amounted to £1,260,977, of which £1,057,021 was derived from imperial, and £203,956 from provincial taxation. The civil expenditure in the same year amounted to £904,670, of which £440,232 was on imperial, and £464,438 on provincial account. Of the total revenue £603,056, or just one-half, was derived from the land. There were 196 criminal and 119 civil courts at work in 1873-74. The regular police consisted of a force of 7539 officers and men, besides a municipal police of 988. The total cost of the regular and municipal police in 1873-74 amounted to £130,674. The troops quartered in the Central Provinces are as follows:—Europeans—3 batteries of artillery (with 18 guns), and 2 regiments and 1 company of infantry; natives—2 regiments of cavalry and 6½ regiments of infantry. The European troops numbered 2462, and the native troops 5475, giving a total of 7937 officers and men, kept up at a cost of £277,781. For the education of the people Government maintains, or subsidizes under its grant-in-aid system, 1532 schools, attended in 1873-74 by 76,781 pupils, and maintained at a total cost of £55,734, to which the state contributed £31,628, or over one-half. These schools are exclusive of private institutions not receiving support from the state.

Besides the 19 British districts of the Central Provinces described in the foregoing paragraphs, and to which alone the above statistics refer, there are also 15 small feudatory states, comprising a total area of 28,834 square miles, with a population of 1,049,710 souls, made up as follows:—Hindus, 638,187; Muhammadans, 7718; Buddhists and Jains, 14; Christians, 5; and "others" (consisting of aboriginal tribes), 403,786. The following are the details of area population, revenue, &c., of each of these states as officially returned in 1874-5:—(1.) Bastar: area, 13,062 square miles; population, 78,856; supposed gross revenue, £9213, 10s.; annual tribute to the British Government, £305, 12s. (2.) Karond: area, 3745 square miles; population, 133,483; estimated revenue, £2000; tribute, £355. (3.) Rajgarh-Bargarh: area, 1486 square miles; population, 63,304; estimated revenue, £750; tribute, £40. (4.) Sarangarh: area, 540 square miles; population, 37,991; estimated revenue, £800; tribute, £135. (5.) Pátná (under British management): area, 2399 square miles; population, 98,636; estimated revenue, £2500; tribute, £60. (6.) Sonpur: area, 906 square miles; population, 130,713; estimated revenue, £1800; tribute, £500. (7.) Kairá Khol: area, 833 square miles; population, 12,660; estimated revenue, £600; tribute, £58. (8.) Bámrá: area, 1988 square miles; population, 53,613; estimated revenue, £600; tribute, £35. (9.) Sakti: area, 115 square miles; population, 8394; estimated revenue, £813; tribute, £35. (10.) Kawardo: area, 887 square miles; population, 75,462; estimated revenue, £5356; tribute, £1600. (11.) Kondá or Chhuikhádán: area,

174 square miles; population, 29,590; estimated revenue, £2203; tribute, £1100. (12.) Kánker: area, 1000 square miles; population, 43,552; estimated revenue, £1500; pays no tribute. (13.) Khairgarh (under British management): area, 940 square miles; population, 122,264; estimated revenue, £11,763; tribute, £4700. (14.) Nandgón: area, 884 square miles; population, 148,454; estimated revenue, £8595; tribute, £4600. (15.) Makrái: area, 215 square miles; population, 13,648; estimated revenue, £2200; pays no tribute.

—Including the 19 British districts and the 15 small feudatory states, the Central Provinces comprise a total area of 113,797 square miles, and have a population of 9,251,229 souls, made up as follows:—Hindus, 6,518,137, or 70·46 per cent; Muhammadans, 240,965, or 2·60 per cent; Buddhists and Jains, 36,583, or 0·40 per cent; Christians, 10,482, or 0·11 per cent; and "others," 2,445,062, or 26·43 per cent. (w. w. h.)

CENTUMVIRI, among the Romans, were judges appointed to decide common causes among the people, of whom three were chosen out of each tribe. The extent of their powers has not been exactly ascertained. It is not unlikely that they were originally intended to deal with questions concerning quiritian ownership, which determined the status of the citizens. Hollweg asserted that their jurisdiction was confined to civil cases; but this is doubtful. (See Hollweg, *Ueber die Competenz des Centumviralgerichts*; Tigerström, *De Judicibus apud Romanos*.)

CENTURION, among the Romans, an officer in the infantry who commanded originally a hundred men (whence the name), but afterwards an indefinite number—the sixtieth part of a legion. Centurions were of two grades, and were chosen by the tribunes. Their duties were to drill the soldiers and appoint their tasks, and they had power to punish minor offences.

CEOS (*Kéws*), the modern Zea or Tzia, an island in the Aegean Sea, belonging to the group of the Cyclades and the eparchy of Syra, 14 miles off the coast of Attica. Its greatest length is about 13 miles, and its breadth about 8. It gradually rises towards the centre, where it culminates in Mount Elias, 1860 feet high. Among its natural productions are lemons, citrons, olives, wine, and honey; and it also exports a considerable quantity of valonia. There were formerly four towns of some importance in the island:—Iulis, about three miles from the north-west shore; Corcëssia, the harbour of Iulis, with a temple of Apollo Smintheus in the neighbourhood; Carthæa in the south-east; and Poicëssa in the south-west. Of these Iulis is represented by the town of Zea, and Carthæa by the village of 'S tais Polais; and traces of the other two can still be made out. In ancient times Iulis was the birthplace of the lyric poets Simonides and Bacchylides, the philosophers Prodicus and Ariston, and the physician Erasistratus; and the excellence of its laws was so generally recognized that the title of Cean Laws passed into a proverb. One of them, which forbade a citizen to protract his life beyond sixty years, affords a curious instance of the application of utilitarian principles. The present population of the island is about 8000, of which the capital has about 4300.

CEPHALONIA, or CEFALONIA, the ancient *Cephalenia*, an island belonging to the kingdom of Greece, and the largest of those known as the Ionian Islands, is situated on the west side of the mainland, almost directly opposite the Gulf of Corinth. Its extreme length is 31 miles, and its breadth varies from about 20 miles in the southern portion to three or less in the projecting part, which runs parallel with the island of Ithaca, at a distance of about four miles across the strait of Guiscardo or Viscaro. The whole island, with its area of 348 English square miles, is covered with rocky hills of varying elevation, the main range running from north-west to south-east. The ancient

mount Ænos, now Elato, Monte Negro, or the Black Mountain, has a height of 5300 feet, and frequently retains the snow for several months. It is not only the loftiest part of the sierra, but also the highest land in the whole Ionian group. The name "Black" was given from the darkness of the pine woods which still constitute the most striking feature in Cephalonian scenery, although their extent has been greatly curtailed by fire. On the summit there is still to be seen an ancient altar, surrounded by the bones of former sacrifice. The island is ill supplied with fresh water; there are few permanent streams except the Rakli, and springs are apt to fail in dry summers. In the western part of the island a gulf runs up from the south a distance of about seven miles; on its east side stands the chief town Argostoli, with about 9000 inhabitants, and on its west side the rival city of Lixuri, with 6000. About five miles from Argostoli is the Castle of St George, a building of Venetian origin, and the strongest fortification in the island; and between St George and the village of Mataxata, where Byron at one time resided, are several large catacombs. On an eminence east-south-east of Argostoli are the ruins of the ancient Cranii, and Lixuri is close to or upon those of Pale; while on the other side of the island are the remains of Samos on the bay of the same name, of Proni or Pronni, further south above the vale of Rakli and its blossoming oleanders, and of an unknown city near the village of Scala. The ruins of this city include Roman baths, a brick-built temple, rock-cut tombs, and tessellated pavements; and Cranii, Proni, and Samos are remarkable for stretches of Cyclopean and Hellenic walls, partly of the most irregular construction, and partly preserving almost unimpaired the results of the most perfect skill. The inhabitants of Cephalonia have all along been extremely active; and no slight amount of toil has been expended in the construction of terraces on the steep sides of the hills. Owing to the thinness of the population, however, but a small proportion of the soil is under cultivation, and the quantity of grain grown in the island is comparatively meagre. The staple is the currant, in the production of which the island surpasses Zante. The fruit is smaller than that of the Morea, and has a peculiar flavour; it finds a market mainly in Holland, Belgium, and Germany. The grape vine is also grown, and the manufacture of wine is a rising industry. The olive crop is of considerable importance, and within recent years the culture of cotton in the low grounds has been successfully attempted. Manufactures are few and undeveloped, but lace from the aloe fibre, Turkey carpets, and basket-work are produced by the villagers, and boats are built at both the principal towns. Among recent improvements may be mentioned the erection of two steam-mills and the introduction of steam-boat communication between Argostoli and Lixuri. In 1873 there were exported from the island 19,603,933 lb of native currants, of the value of £123,176; and in the same year the re-exportation of Morea currants was 4,567,192 lb, valued at £25,728. The total imports, which consist mainly of wheat, maize, barley, and rye, amounted to £287,493. Of all the seven islands Cephalonia and Zante are most purely Greek; and the inhabitants display great mental activity. Of several contributors to the national literature may be mentioned Bishop Maniati, author of a treatise on the schism of the Eastern and Western churches, and Andrea Lasearato, a vigorous political writer and keen defender of the British protectorate, who brought himself into great trouble by the freedom of his attacks in his *Mysteries of Cephalonia*.

In the Homeric poems, Cephalonia is mentioned under the name of Same, and its inhabitants, among the subjects of Ulysses, are designated Cephallenes. In the Persian war they took but little

part; in the Peloponnesian they sided with the Athenians. The town of Pale was vainly besieged by Philip of Macedon in 218 B.C., because it had supported the Ætolian cause. In 189 B.C. all the cities surrendered to the Romans, but Same afterwards revolted, and was only reduced after a siege of four months. The island was presented by Hadrian to Athens, but it appears again at a later date as "free and autonomous." After the division of the Roman empire, it continued attached to Byzantium till 1082, when it was captured by Robert Guiscard, who died, however, before he could repress the revolt of 1085. In 1204 it was assigned to Gaius, prince of Tarentum, who accepted the protection of Venice in 1215; and after 1225 it was held along with Santa Maria and Zante by a succession of five counts of the Toeco family at Naples. Formally made over to Venice in 1350 by the prince of Tarentum, it was afterwards captured by the Turks in 1479; but the Hispanico-Venetian fleet under Beudetto Pessaro and Gonsalvo of Cordova effected their expulsion in 1500, and the island continued in Venetian possession till the fall of the republic. For some time it was administered for the French Government, but in 1809 it was taken by the English under Collingwood. Till 1813 it was in the hands of Major de Bosset, a Swiss in the British service, who displayed an industry and energy in the repression of injustice and development of civilization only outdone by the despotism of Sir Charles Napier, who held the same office for the nine years from 1818-1827. During the British protectorate the island made undoubted advances in material prosperity, but was several times the scene of political disturbances. It retained longer than the sister islands traces of feudal influence exerted by the landed proprietors, but has been gradually becoming more democratic. Under the Venetians it was divided into eight districts, and an elaborate system of police was in force; since its annexation to Greece it has been broken up into twenty demarchias, each with its separate jurisdiction and revenues, and the police system has been abolished.

A special treatise on the antiquities of Cephalonia was written by Petrus Mauroceus. See also Holland's *Travels*, 1815; Ansted's *Ionian Islands*, 1863; Viscount Kirkwall's *Four Years in Ionian Islands*, 1864; Wiebel's *Die Insel Kephallonia*; and Parliamentary papers.

CERAM, or SIRANG, an island of the East Indian Archipelago, situated to the west of New Guinea, and belonging to the Dutch Government of the Moluccas. It lies between 2° 45' 30" and 3° 30' 30" S. lat., and extends from 128° to 131° 10' E. long.; its greatest length is about 200 miles, its greatest breadth about 50, and its area upwards of 6000 square miles. It is divided into two parts, Great Ceram and Little Ceram or Huvamohel, united by the isthmus of Taruno; and, for administrative purposes, the eastern portion is assigned to the residency of Banda, while the western belongs to that of Amboyna. A chain of mountains traverses the island from east to west, and attains in various parts a height of upwards of 8000 feet. The loftiest summit—Nusa Keli—has an elevation of 9500 feet; and others of mark are Salagor, Trier, and Tomache. The coast is for the most part rocky and precipitous; but it is broken in several places by considerable bays, of which the most important are Hatuvi and Savaai on the north, and Huvamohel, Amahay, Nusa Laut, and Selan on the south. The country is well watered with streams, which are of very little use, however, for navigation or systematic irrigation. Several hot springs have been discovered, and earthquakes are not unfrequent. A large part of the interior is covered with dense and gloomy forests, and except along the coasts the population is very scant. For the naturalist Ceram is a comparatively uninteresting island, without any characteristic species or abundance of specimens. The Bandanese pay occasional visits to shoot bears and deer; there are numbers of wild goats and cattle; and among the birds are mentioned cassowaries, cockatoos, birds of paradise, and the swallows that furnish the edible nests. A large number of fish are to be found in the various rivers; and as early as 1860 no fewer than 213 species were described by Dr Bleeker in the *Natuurkundig Tijdschrift v. N. I.* The most valuable timber trees are the iron-wood and the makila. Rice, maize, cocoa-nuts, sugar-cane, and a variety of fruits are grown; but by far the most important production is the sago palm, which grows abundantly in the swampy districts

especially of Eastern Ceram, and furnishes a vast supply of food, not only to Ceram itself, but to other islands to the east. The Dutch settlers at Amboyna have recently established cocoa plantations at various points, and the Government encourages their formation. The inhabitants are mostly gathered in villages along the coast; they are partly native Alfuroes and partly immigrant Malays, with a considerable intermixture of Buginese, Macassars, Balinese, and other races of the archipelago. Christianity has been introduced in various districts, especially along the southern coast, but as yet with but little practical benefit. A baneful influence has been exerted by a secret society called the Kakian Union, to which pagans, Mahometans, and Christians indiscriminately attached themselves; and it has several times cost the Dutch authorities considerable efforts to frustrate their machinations. A full account of the union will be found in the fifth year of the *Tijdschrift van Ned. Ind.* The total population is estimated at 195,000, of whom the lands on the south coast contain 65,000, the lands on the north coast 40,000, and the south-western peninsula a large portion of the remainder. There was a Dutch fort at Kambello, on the west side of Little Ceram, as early as 1646. See Wallace's *Malay Archipelago*, and Bickmore's *Eastern Archipelago*.

CERBERUS (Κέρβερος), in Greek mythology, the dog which guarded the entrance to Hades, not against incomers, but against whoever might seek to escape. In Hesiod (*Theog.* 310), he is a many-headed monster with a fearful bark, but usually he was represented with three heads and the body of a dog such as haunted battlefields,—sometimes also with the tail of a snake. The same number of heads occurs in other beings connected with the lower world, as in Hecate "triformis" and Hermes "trikephalos." The most difficult of the labours imposed on Hercules was to bring Cerberus to the upper world, and in this he was forbidden by Pluto to use any weapons. Of the various suggested derivations of the name perhaps the most satisfactory is that which connects it with *ἐρεβος*, the darkness of Hades.

CERDONIANS, a Gnostic sect, founded by Cerdo, a Syrian, who came to Rome about 140, but concerning whose history little is known. They held that there are two first causes—the perfectly good and the perfectly evil. The latter is also the creator of the world, the god of the Jews, and the author of the Old Testament. Jesus Christ is the son of the good deity; he was sent into the world to oppose the evil; but his incarnation, and therefore his sufferings were a mere appearance. Regarding the body as the work of the evil deity, the Cerdonians formed a moral system of great severity, prohibiting marriage, wine, and the eating of flesh, and advocating fasting and other austerities. Origen attributes to Cerdo the opinion,—which was certainly held by the more famous Marcion, his contemporary and, in some respects at least, his follower,—that there are three first causes—the perfectly good, the perfectly evil, and the imperfect, whom Marcion calls "the just" (τὸ δίκαιον), and who is the creator of the world and the god of the Jews. Besides the Old Testament, Cerdo rejected also the New, except part of Luke's Gospel and of St Paul's Epistles. See MARCION and GNOSTICS.

CERES, in Mythology, was the Roman goddess of seed and harvest, worshipped jointly with Liber (Bacchus) and Libera (Proserpine). No special myth or personal history is known to have been attached to her. But early in the times of the Republic, when Greek deities were introduced into Rome on the advice of the Sibylline books, Demeter, the Greek goddess of seed and harvest, whose worship was largely spread in Sicily and Lower Italy, usurped in Rome the divine position which Ceres held before; or rather to Ceres were added the religious rites

which the Greeks paid to Demeter, and the mythological incidents which originated with her. These rites were Greek in their language and forms, the priestesses were Greeks, and the temple was Greek in its architecture. Her principal festivals were (1) the *Cerealia* (April 12–19), corresponding in the main idea with the Eleusinia, and (2) the *Jejunium Cereris* (October 4), corresponding to the Thesmophoria of Demeter. The *Cerealia* included the spectacle of hunting a fox with a toreh attached to his tail. Her temple in Rome had been destroyed by fire, and was rebuilt by Augustus. Claudius attempted to introduce the mysteries of Eleusis into Rome in connection with her worship.

As regards the Greek goddess, the chief interest of her worshippers was concentrated on the myth which told how her only daughter Persephone (Proserpine) had been carried off in a chariot by Pluto, the god of the lower world, from the fields of Enna in Sicily, where she was gathering flowers; other districts also were assigned for this incident, but the Romans naturally preferred Enna as being the nearest. Demeter wandered over the earth searching for her daughter in vain, in her anguish refusing food or drink, and threatening a famine for mankind, till Zeus agreed to allow Persephone in future to live half the year with her mother on the earth. The other half she must remain with Pluto in the lower world. From the myth so far it was an obvious step to think of Demeter as a mother always anxious for her child, yearning through half the year to see her again, and sad through the other half at the prospect of her leaving again. But a deeper meaning appears to have been found in the myth by those who were initiated into the mysteries of Eleusis, in which seems to have been taught the principle of a new life after death, founded on the return of Persephone to the upper world, or rather on the process of nature by which seed sown in the ground must first die and rot before it can yield new life, a process which the annual going and coming of Persephone was designed to illustrate. To make more explicit this connection of Demeter with seed-sowing, the myth tells how, in searching for her daughter, she was hospitably received among other places at Eleusis in Attica, and how, when leaving Eleusis, she gave to Triptolemus, the king's son, her chariot drawn by winged snakes, with the injunction to travel over the world teaching men to cultivate grain as she had then begun to teach them. At the Thesmophoria, a festival in which only married women took part, Demeter was regarded as having instituted certain laws (*θεσμοί*) for regulating life, in particular the married life of women. In the Cretan myth of Demeter she was connected with a hero Jasion, said to have been the first to sow grain, to whom she bore a son, Plutos. Poseidon, the god of the sea, appears as repugnant to her in the myth, according to which she took the form of a horse to escape him, but was overtaken, and finally bore to him the winged horse Arion. It may have been with reference to this that she was figured in an ancient image at Phigaleia as having a horse's in place of a human head. Her attributes were a veil and diadem on her head, ears of corn or poppies in her hand. Her principal sacrifice consisted of pigs. Demeter was a daughter of Kronos and Rhea. Zeus was the father of Persephone.

CERIGNOLA, a town of Italy, in the south of the Neapolitan province of Capitanata, 24 miles S.E. of Foggia, pleasantly situated on an eminence which commands an extensive view. The surrounding plain is well cultivated, and produces large quantities of almonds and cotton. Linen is manufactured by the inhabitants. Cerignola is divided into an old and new town, and contains a hospital, a college, and several convents. Here, on the 28th April 1503, the Spaniards, under Gonsalvo de Cordova, defeated

the French, when the leader of the latter, the Duc de Nemours, was slain. In the neighbourhood, to the west of the Lago di Salpi, are the ruins of the ancient Apulian town Salapia. Population about 17,500.

CERIGO, the ancient *Cythera* (Κύθηρα), one of the Ionian islands, situated at a distance of not less than 150 miles from Zante, but only about 8 miles from Cape Malea on the southern coast of Greece. Its length from N. to S. is nearly 20 miles, and its greatest breadth about 12; its area is 114 square miles. The general character of the surface is rocky and broken; but streams abound, and there are various parts of considerable fertility. Two caves, of imposing dimensions, and adorned with stalactites of great beauty, are the most notable among its natural peculiarities; one is situated at the seaward end of the glen of the Mylopotamus, and the other, named Santa Sophia, about two hours ride from Capsali. Less of the ground is cultivated and more of it is in pasture land than in any other of the seven islands. Some wine and corn are produced, and the quality of the olive oil is good. The honey is still highly prized, as it was in remote antiquity; and a considerable quantity of cheese is manufactured from the milk of the goat. Salt, flax, cotton, and currants are also mentioned among the produce. The people are industrious, and many of them go to seek employment as labourers in the Morea and Asia Minor. Unfortunately the island has hardly a regular harbour on any part of the coast; and from its situation at the meeting as it were of seas, the currents in the neighbourhood are strong, and storms are very frequent. The best anchorage is at San Nicolo, at the middle of the eastern side of the island. The principal village is Capsali, a place of about 1500 inhabitants, at the southern extremity, with a bishop, and several convents and churches; the lesser hamlets are Modari, Potamo, and San Nicolo. There are comparatively few traces of antiquity, and the identification of the ancient cities has not been satisfactorily accomplished. The capital bore the same name as the island, and consisted of a maritime and an inland portion, distant from each other about 10 stadia. The site of the upper city is probably at Paleopoli, about three miles from the present port of Avlemona; but no trace can be discovered of the famous shrine of the Venus of Cythera, whose worship had been introduced from Syria, and ultimately spread over Greece. The present inhabitants of the island are very badly educated. The number of priests is out of all proportion to the population, and no fewer than 260 churches or chapels have been counted. Spiridion Vlandi, author of an Italian and Romanic lexicon, published at Venice in 1806, is one of the few Cerigotes who have made appearance in literature. In 1857 the total population was 13,256, the excess of females being 1028; it appears now to number about 10,000. At a very early date Cythera was the seat of a Phœnician settlement, established in connection with the purple fishery of the neighbouring coast. For a time dependent on Argos, it became afterwards an important possession of the Spartans, who annually despatched a governor named the Cytherodices. In the Peloponnesian War, Nicias occupied the island, and in 393 it was captured by Conon the Athenian. By Augustus it was bestowed on Eurycles. Its modern history has been very much the same as that of the other Ionian Islands; but it was subject to Venice for a much shorter period—from 1717 to 1797. See the works referred to under CEPHALONIA.

CERIGOTTO, an island of Greece, belonging to the Ionian group, and situated between Cerigo and Crete in 35° 50' N. lat. and 23° 20' E. long. It was anciently known as *Ægilia*, and is now called by its inhabitants Lius. With an area of about 10 square miles it supports a population of about 300, who are mainly Cretan refugees,

and in favourable seasons exports a quantity of good wheat. It was long a favourite resort of Greek pirates.

CERINTHUS was the founder of one of the earliest heretical sects of the Christians. He was brought up in Egypt (Theod. *Hær. Fab.* ii. 3), but removed to Asia Minor, where he propagated his doctrines. He flourished, according to Eusebius (*Hist. Eccl.* iii. 28) in the time of Trajan (98–117). Irenæus relates a story which represents him as a contemporary of the apostle John (*Contra Hær.* iii. 3, 4). He says that John, the disciple of the Lord, when in Ephesus went to bathe, and when he saw Cerinthus inside, he leapt from the bath without bathing, crying out, "Let us flee, lest the bath fall, for Cerinthus the enemy of the truth is within." Irenæus heard this story from some people who heard it from Polycarp, who may have heard it directly, or more likely at second-hand, from some of the friends of St John. The same story is told in regard to Ebion, but not on so good authority. We know nothing of the death of Cerinthus.

We possess three different authorities for the opinions of Cerinthus, to some extent inconsistent with each other,—Irenæus, Caius the Roman presbyter, and the third unknown. Lipsius has tried to prove that the third was Hippolytus.

According to Irenæus (*Contra Hær.* i. 26), Cerinthus taught "that the world was not made by the supreme God, but by a certain power which was separated and distant from the supreme authority, which is over all, and which was ignorant of the God over all." He also maintained "that Jesus was not born of a virgin, but was the offspring of Joseph and Mary, born like all other human beings, and that he was juster and wiser and more prudent than all." He affirmed also "that after his baptism the Christ came down into him in the form of a dove from the Lord, who is above all, and that then he proclaimed the unknown Father and performed miracles, but towards the end the Christ flew away from Jesus, and that Jesus suffered and was raised up, but that the Christ remained impassible, being spiritual." The same information is given in the treatise *The Refutation of Heresies*, first ascribed to Origen, and now to Hippolytus (lib. vii. c. 33), in the very words of Irenæus, and the writer repeats it in his summary (x. 21), with the addition that it was by an angelic power that the world was made. Irenæus (iii. xi. 7, see also Jerome, *De Viris Ill.* c. 9) also informs us that the gospel of St John contained statements which were specially intended to remove the error of Cerinthus, and of the Nicolaitanes who held the opinion before him, that the maker of the world and the supreme God were different.

From Caius the Roman presbyter our information is as follows. "Cerinthus, by means of revelations which pretend to be written by a great apostle, speaking falsely, introduces wonders which he speaks of as if they had been shown to him by angels, saying that after the resurrection the kingdom of Christ was to be on earth, and that again men in bodily form would live in Jerusalem and be subject to lusts and pleasures. And being an enemy to the Scriptures, and wishing to lead astray, he affirms that a thousand years will be spent in marriage feasting" (*Eus. Hist. Eccl.* iii. 28). It is plain from this passage that Caius derived his opinion of the character of the millennium in which Cerinthus believed from the revelations which Cerinthus wrote in the name of a great apostle. Dionysius, bishop of Alexandria, affirms that some maintained that the Apocalypse was not the production of the apostle John, not even of a saint, but of Cerinthus, who established the sect called Cerinthian from him, and who wished to give a respectable name to his own fiction (*Eus. Hist. Eccl.* vii. 25). The context proves conclusively that Dionysius refers specially to Caius, whose words he partly quotes

and partly paraphrases. The paraphrase shows how easy it is to invent a discreditable character and doctrine for a heretic. He says that Cerinthus believed "that the kingdom of Christ would be on earth, and that being fond of the body and altogether carnal, he dreamt that he would revel in these delights for which he longed—the satisfaction of the stomach and the parts below it, that is, in foods, and drinks, and marriages, and the means by which he thought that he could more decently procure these, namely, feasts and sacrifices and the slaying of victims." It is barely possible that Dionysius may have had access to other sources of information than the statement of Caius, but the probability is all on the other side. He was a determined antagonist of millenarianism, and was prepared to see gross sensuality in the adherents of the doctrine; but there is no good evidence that Cerinthus was sensual. We cannot even affirm that he was a millenarian, for Caius evidently formed his opinion on this matter in consequence of his belief that Cerinthus wrote the Revelation ascribed to St John—a belief which others seem to have shared with him (Epiph. *Hær.* li., 3).

Our third source is not extant in its original form, but is to be traced in Epiphanius (*Hær.* xxviii.), and in almost all the Latin writers on heresy contained in Oehler's first volume of his *Corpus Hæresilogicum*, but most markedly in Philastrius (c. 36) and Pseudo-Augustinus (c. 8). According to Irenæus, Cerinthus carefully distinguished between the historical man Jesus and the æon Christ. This source evidently represented Jesus and Christ as the same, and it was the descent of the Holy Ghost after his baptism that rendered Jesus Christ capable of performing miracles. Jesus Christ was the son of Joseph and Mary, and was for the short time of his ministry miraculously endowed through the descent of the Holy Ghost, but the Holy Ghost left him before he suffered, and he died and did not rise again, but will rise again when the general resurrection takes place.

Cerinthus, according to these authorities, affirmed that the world was made by angels, and that the law and the prophets were given by one of the angels who made the world. Philastrius thus sums up the other features of the heresy. "He taught circumcision and the observance of the Sabbath . . . He does not receive the apostle Paul, he honours Judas the traitor, he receives the gospel according to Matthew, he despises three gospels, he rejects the Acts of the Apostles, he blasphemes the blessed martyrs." Epiphanius makes him accept only a portion of the gospel of St Matthew. He thinks that he was one of those Judaic Christians referred to in Acts xv. 24, that he also found fault with the apostle Peter for going to Cornelius (Acts xi. 3) and created a commotion against Paul in connection with Titus (Acts xxi. 28), and that St Paul alludes to a practice of Cerinthians in noticing baptism for the dead.

Most of these statements are probably incorrect, and some of them are to be rejected without hesitation for chronological reasons. Some of the writers mention a Merinthus, who was either the same as Cerinthus or was confounded with him. It is likely that this is not the only confusion in these accounts, and we may well doubt whether either Justin or Hippolytus could be the source from which they were drawn, or that the account contained in it was more accurate than that of Irenæus.

Cerinthus is mentioned in nearly all the historians of early Christianity, but special reference may be made to Lardner's works, vol. viii. (Kippis's edition); Mansel's *Gnostic Heresies* (London, 1875); Lipsius's "Gnosticismus," in Ersch and Gruber, p. 257; his *Zur Quellenkritik des Epiphanius* (Vienna, 1865), p. 115, and his *Die Quellen der ältesten Ketzergeschichte* (Leipsic, 1875), p. 39; and Adolf Harnack's *Zur Quellenkritik der Geschichte des Gnosticismus* (Leipsic, 1873), p. 46.

(J. D.)

CERRETO, a town of Italy, in the Neapolitan province of Benevento, on the Cusano. It is well-built, is agreeably situated on the slope of Monte Matese, and has a fine cathedral, collegiate church, and seminary. With Telesse it forms the see of a bishop. There are several cloth manufactories, and excellent wine is produced in the neighbourhood. The town suffered greatly from the plague in 1656, and from an earthquake in 1688. Population, 7000.

CERRO DE PASCO, a town of Peru, in the department of Junin, on the table-land of Bombon, 14,280 feet above sea-level. The houses are ill-built, and there are no public buildings of importance. Living is dear, the neighbourhood is unfertile, and the climate is cold and stormy. The silver mines, discovered in 1630, are numerous, but not so productive as in past times. Population, consisting chiefly of Indians and a mongrel race, about 13,000.

CERTALDO, a market-town of Tuscany, on the right bank of the Elsa, in the province of Florence, and 15 miles south-west of that city. It was the birthplace of Boccaccio, whose house, repaired in 1823 by the Marchesa Lenzi Medici, is still to be seen. One of the rooms contains, besides some of the ancient furniture, the remnants of the poet's tomb, his autograph, and his picture. Not far from the house stands the Church of St Michael and St James, from which Boccaccio's remains were removed in 1783. In December 1875 a monument to his memory was erected by the authorities of the town. The older part of Certaldo is on the summit of a steep and conical hill, and contains the building which was once the stronghold of the Counts Alberti, the lords of the place before it became subject to Florence. There also dwelt the vicars of Certaldo, who ruled the town and district for Florence, till the reign of the reformer Peter Leopold. The new burgh is situated along the course of a road that skirts the foot of the hill. Population about 2000.

CERVANTES-SAAVEDRA, MIGUEL DE (1547-1616), the author of *Don Quixote*, was born at Alcalá de Henares, the ancient *Complutum*, a small town in the province of New Castile, in 1547. The day of his birth is not known, but as he was baptized on the 9th of October it is conjectured from his Christian name that he was born on St Michaelmas day preceding. The place of his nativity also remained in doubt until the year 1748, when Don Juan de Yriarte found in the Royal Library of Madrid a manuscript entitled *La Verdadera Patria de Miguel de Cervantes*, written by the learned Benedictine Martin Sarmiento. Till then seven cities, Madrid, Seville, Lucena, Toledo, Esquivias, Alcazar de San Juan, and Consuegra, had contended for the honour of being his birthplace, although in the *Topography of Algiers*, by Father Hædo, published in 1612, mention was made of Cervantes as a native of Alcalá de Henares, and the genealogist Mendez de Silva, in his tract on Nuño Alfonso, published in 1648, had also spoken of him as a noble Castilian gentleman of the same town. All doubts on the subject, their long ignorance as to which is one of the many proofs of the carelessness with which the Spaniards have treasured what belongs to the memory of their illustrious countryman, were finally resolved by the discovery of the petition for an inquiry into his conduct at Algiers addressed by Cervantes to the Government in 1580. The family of Cervantes, which had for some generations attached to their patronymic the name of Saavedra, was of respectable if not noble origin. The patriotic zeal of some later biographers has even claimed for it affinity to the royal blood of Castile. The cradle of the race was Galicia, from which province the ancestors of Cervantes emigrated at an early date. Members of the family accompanied Ferdinand III. on his expedition against the Moorish kingdom of Seville and obtained a share of the conquered territory. The grand-

Birth at
Alcalá de
Henares,

father of Miguel was Juan de Cervantes, a knight of some distinction, who held the office of *corregidor* of Ossuna at the beginning of the 16th century. His son Rodrigo married in 1540 Leonora de Cortinas, a lady of Esquivias, of birth equal to his own but, it is presumed, of no greater fortune. There were four children of the marriage, two sons, Rodrigo and Miguel, and two daughters. Although ranking themselves with the *hidalgos*, the parents must have been, at the birth of their younger son, in humble circumstances. The biographers have been able to glean but few details of the early life of our hero, and for these they are indebted almost entirely to the chance allusions in Cervantes's own writings. He studied grammar and the humanities under a master of some repute, Lopez de Hoyos, and, according to a doubtful tradition, spent two years at the university of Salamanca, residing in the Calle de Moros. That he received a fair education according to the standard of the age, and had an extensive though not exact knowledge of classical and general literature, his works bear witness. When a boy he describes himself as having attended the representations of the first regular company of Spanish actors under Lope de Rueda, the founder of the dramatic art in Spain. Upon the occasion of the magnificent obsequies held in honour of Isabel de Valois, the wife of Philip II., in 1568, the most advanced scholars of Lopez de Hoyos competed in the literary exercises, in Latin and in Spanish, which formed part of the funeral ceremony; and chief among the victors was Miguel de Cervantes, who is mentioned by his master in the most affectionate and laudatory terms as his "dear and beloved pupil." These compositions, among which were sonnets, *letrillas*, and *redondillas*, have perished, together with many of the early poetical essays of their author, probably with no loss to the world or to his reputation. In his *Journey to Parnassus* Cervantes speaks of these effusions of his youthful muse with characteristic modesty and candour, averring that "from his tenderest years he had loved the sweet art of poesy," and had composed endless ballads and sonnets, good and bad, but confessing with a touching humility that Heaven had not granted him the poet's grace. Among the last works belonging to this period, of which their author speaks with more complacency, was *Filena*, a pastoral poem, esteemed sufficiently good by his contemporaries to earn for the author a place among the multitude of those who wrote themselves poets in that fruitful harvest-time of Spanish literature.

In 1568 there came to Madrid—charged with a message of condolence from the Pope to Philip II., on the death of his son Don Carlos, and with sundry complaints respecting default of allegiance to Rome—the Cardinal Acquaviva, who, though only in his twenty-fifth year, had already earned a name for culture and a good disposition to letters. With him Cervantes took service as a *camarero* or page,—an employment held to be no humiliation in that age even to young men of noble birth,—returning in the suite of his patron to Rome by way of Valencia, Barcelona, and the south of France. Apparently the post was not to the taste of one in whom the sight of Italy—then for the greater part a fief of Spain—awakened more of warlike than of poetic ambition. In the beginning of 1570 the cardinal's page exchanged his livery for the soldier's uniform, enlisting in the company of the famous Captain Don Diego de Urbina of the regiment of Don Miguel de Moncada. It was the period when the military glory of Spain was at the highest, and the profession of arms the surest road to advancement. The first campaign of Cervantes was made at sea, his regiment being engaged in the expedition which, in the summer of 1570, under the orders of the Papal general, Marco Antonio Colonna, made an ineffectual attempt to relieve the Island of Cyprus, then

hotly besieged by the Turks. The capture of Nicosia by the Mahometans, and the fall of the island, which spread consternation throughout Christendom, gave rise to the memorable Holy League against Selim II. Through the exhortations of the Pope, Pius V., Spain and Venice were induced to lay aside for a time their old dissensions and to unite with Rome in an attempt to bridle the Ottomans, then in the flush and vigour of their genius. The pact between these Christian powers was formally ratified on the 25th of May 1571, the confederates binding themselves to "make perpetual war" not only against the Turks but against the Moors of Algiers, Tunis, and Tripoli.

The armament provided—the expenses of which were distributed among the three states in the proportion of three-sixths to Spain, two-sixths to Venice, and one-sixth to Rome—was to consist of 200 galleys of war, with 100 store-ships, 50,000 infantry, 4500 light horse, and a sufficient supply of artillery and ammunition. The generalissimo whom the unanimous voice of the allies called to the command of this fleet—the most formidable which had ever been assembled in the Mediterranean—was Don John of Austria, the natural son of Charles V., then in his twenty-fourth year,—a youth not more recommended by his near connection with the Spanish king than by his brilliant talents, amiable character, and great popularity. The mutual jealousies and fears of the allied princes, and the hesitation of Philip II. to entrust so important a command to his half-brother, the object of his secret envy and distrust, caused many delays in the assembling of the Christian forces, and gave the Turks ample time for preparation. The armada, after rendezvousing at Messina, put to sea finally in quest of the enemy on the 15th of September. The company in which Cervantes still served as a private soldier was embarked in the galley "La Marquesa," commanded by Francisco San Pietro. After relieving and provisioning Corfu, Don John came up with the Turkish fleet on the 7th of October, drawn up in order of battle in the Gulf of Lepanto. The Christians advanced in three divisions, their right commanded by the Genoese admiral, Juan Andrea Doria, the centre under Don John himself, and the left under Agostino Barbarigo, the Venetian Proveditore; the Marques de Santa Cruz, with his squadron, being in reserve. The "Marquesa" was on the left wing, having on board Miguel de Cervantes, who lay in his cabin ill of a fever. On coming into action, his ship being in the van of the squadron, Cervantes's captain and comrades besought him to remain quietly in his bed, but he, according to the sworn testimony of ear-witnesses, asked them what would they think of him if he did not do his duty, and declared his resolve to die fighting for God and his king, rather than remain under shelter and take care of his health. His entreaties to be allowed to share in the fighting having been granted, Cervantes was stationed with twelve soldiers under his command in what was reckoned the post of greatest danger, namely, in the boat which hung by the galley side, most exposed to the enemy's fire. Here he performed his part in that glorious day's work so valiantly as to attract the notice of his commanders, even of Don John himself. The vessel immediately opposed to the "Marquesa" was the galley of the Capitan Pasha of Alexandria, who commanded on the Turkish right, bearing the royal standard of Egypt. After a stubborn resistance, and the slaughter of 500 of her crew, she was compelled to surrender, her fate involving the flight or capture of the entire squadron, and contributing materially to the final defeat of the Turks. On their right wing the Christians were less successful,—Marco Antonio Colonna having to encounter the celebrated renegade, Uluch Ali, a sea-captain of great skill and experience, to whose good conduct and abilities Cervantes himself, with characteristic generosity,

Battle of
Lepanto.

bears witness. The issue was highly honourable to the allied arms. The victory at Lepanto, though barren of results, and spoilt by the contentions among the Christian leaders, broke the spell of Turkish invincibility at sea, and is to be reckoned among the most glorious feats of arms ever performed by Spain when at the zenith of her greatness. In this battle, to the remembrance of which he ever fondly clung, which he loved to speak of as the proudest event of his life, Cervantes was severely wounded—receiving two gun-shot wounds in the chest and one in the left hand, which was maimed and rendered useless “for the greater glory of the right,” as its owner said, holding this defect ever after to be his greatest ornament. Lepanto was to Spain what Salamis was to Athens. All Europe rang with the fame of “the man sent from God whose name was John,” according to the fervent exclamation of the grateful Pope when he heard the news of the victory; and the exploits of Doria, Colonna, and Santa Cruz were on all men’s tongues. But while generals and admirals are now forgotten, it is a striking evidence of the power of genius to override even the traditions of patriotism and of warlike glory that of all the memories which survive of this once renowned day, that which remains green and flourishing is of the private soldier who fought in the “*Marquesa*,” of him whom his countrymen love to designate as *El Manco de Lepanto*. It would be absurd to attribute to the single arm of Miguel de Cervantes any appreciable share in the event of that day, but making all allowances for the partiality of his biographers, there can be no reason to doubt that Cervantes did earn a very extraordinary amount of renown for his behaviour in the battle. As a private soldier he was not debarred, according to the fashion of the times, from receiving from his superiors those marks of consideration due to men of good birth and breeding; yet the extraordinary favours bestowed on him by Don John and the other leaders, the letters of credit which they gave him on his return to Spain, the numerous references to him by his contemporaries, and the influence he afterwards exercised among his fellow-captives at Algiers, are sufficient to prove that at this early period of his life Cervantes had attained to much distinction over and above what he had won as a man of letters.

After the battle of Lepanto the lateness of the season compelled Don John to return to Sicily, leaving the Turks leisure to recover from their losses and to recruit their strength. The wounded were tended at Messina, among whom Cervantes was visited in the hospital by Don John in person, receiving upon his recovery a special increase of pay to the amount of three crowns a month. From the company of Moncada our soldier was now transferred to that of Don Ponce de Leon, in the *Tercio de Figueroa*, the most distinguished of all the Spanish regiments of that period—of that famous infantry which sustained the Spanish dominion over half Europe, making, in the words of the chronicler, “the earth tremble with their muskets.” The further enterprizes of the League at sea were checked by the growing dissensions between Spain and Venice, and also by the quarrel now on foot between the former nation and its old rival France. The jealousies between the confederate princes extended to their commanders, and it was in vain that Don John urged upon his allies the necessity of striking another blow at the Turk before he had time to repair his shattered forces. It was not until the 9th of August 1572, that the Christian fleet again set sail for the scene of its great exploit of the year previous. In this second campaign, through the supineness of the leaders, perhaps from some incapacity of the generalissimo, scarcely fitted by age or force of character to control so vast and incongruous a host, but chiefly from the superior skill and vigilance of the Turkish commander-

in-chief, a post now held by Uluch Ali, the armada did nothing more than make a feeble demonstration against the enemy’s fleet, which was found at anchor in Navarino Bay. Cervantes, who has given a minute account of this inglorious affair in his story of the captive in *Don Quixote*, served in this expedition in the squadron commanded by Antonio Colonna. Returning to Messina to winter, the armada was next year dispersed in consequence of the dissolution of the Holy League, the Venetians having concluded a separate peace with the Turks. In 1573 Cervantes took part in the expedition of Don John against Tunis and in the capture of the Goleta—his wounds being still unhealed, as we learn from his letter to Mateo Vasquez. That winter he was in garrison in Sardinia, and in the next spring in Lombardy, being ordered to Messina in August 1574, and thence to Naples. On the 15th of June 1575 he obtained leave of the viceroy, the Duke de Sessa, to visit Spain, and thus ended the first portion of his military career, with small profit but with much honour. During his five years’ active service by land and sea, however, Cervantes had acquired that knowledge of men and life which was so useful to him in after years. He had visited the most famous cities of Italy, and had stored his mind with impressions of her art and literary culture, traces of which are to be found in all his writings, even to the extent of making him liable to the charge of introducing Italian idioms into his style. Of his intercourse with Italian men of letters there is no evidence, though his works furnish abundant testimony of his familiarity with the best models of Italian literature. That he had won the respect and esteem of his commanders as a good soldier is proved by the highly flattering letters which he received from Don John, recommending him to the king for promotion as a man of singular merit and of great services; also from the viceroy of Naples, speaking of him as a worthy but unfortunate soldier who, “by his noble virtue and temper, had secured the good will of his comrades and officers.” Furnished with these letters, which in the event were to prove to him so fatal a possession, Cervantes, with his brother Rodrigo, embarked at Naples in the galley “*El Sol*.” On the 26th of September, when off the coast of Minorca, his vessel fell in with a squadron of Algerine cruizers under the command of the dreaded pirate captain, Arnaut Mami. Attacked by three of the enemy’s ships, the Spanish galley, after an obstinate resistance, in which Cervantes bore a conspicuous part, was forced to surrender to overwhelming odds, and was brought in a prize to Algiers. On the division of the prisoners Cervantes fell to the lot of Deli Mami, a Greek renegade, noted for his ferocity and greed among the Algerines. The letters of Don John and the viceroy of Naples found on this Spanish soldier served but to mislead his captors as to his true rank, and therefore to stimulate their cupidity and to aggravate his sufferings. Being supposed to be able to purchase his liberty at a high price, Cervantes was guarded with special care, and that he might be induced the more quickly to ransom himself, he was loaded with chains and treated with extraordinary rigour. According to the testimony of Father Hædo, in whose curious and important work on the *Topography of Algiers*, published in 1612, we have the most valuable authority for this period of Cervantes’s life, and who was an eye-witness of the cruelties practised in this pirates’ den upon the Christian slaves, the captivity of Cervantes was one of the hardest ever known in Algiers. It was borne with a courage and constancy which, had there been nothing else to make his name memorable, must have sufficed to rank Cervantes among the heroes of his age and country. No episode more romantic is contained in the books of chivalry. No adventures more strange encountered by any knight-

errant. Not Amadis nor Esplandian, nor any of those whose fabled deeds had kindled his youthful imagination displayed a loftier spirit of honour or more worthily discharged his knightly *devoir* than did Miguel de Cervantes when in duress at Algiers. A slave in the power of the bitter enemy of his creed and nation, cut off in the hey-day of his fame from the path of ambition which fortune seemed to have opened to him, no lot could be more cruel than that which in the prime of his manhood and genius fell to our hero. Nor is there any chapter of his life more honourable than the record of the singular daring, fortitude, patience, and cheerfulness with which he bore his fate during this miserable period of five years. With no other support than his own indomitable spirit, forgotten by those whom he had served, unable to receive any help from his friends, subjected to every kind of hardship which the tyranny or caprice of his masters might order, pursued by an unrelenting evil destiny which seemed in this, as in every other passage of his career, to mock at his efforts to live that high heroic life which he had conceived to himself, this poor maimed soldier was looked up to by that wretched colony of Christian captives, including among them many men of higher birth and rank, as their chief counsellor, comforter, and guide. In the formal information laid before the commissary of the Spanish Government at Algiers, Father Juan Gil, of the order of the Redemptorists, very particular testimony is borne by Cervantes's fellow-captives to his character and conduct, as one who bore himself always as a faithful Christian, who cheered those who were despondent, who shared with the poor the little which he possessed, who helped the sick in their necessities, who risked every danger in the cause of the faith, behaving himself always like a true soldier of the king and a noble gentleman,—all which good record is confirmed by the honest father himself of his own personal knowledge.

Captivity
in Algiers.

The captivity of Cervantes in Algiers lasted five years, during which period he never ceased to plot schemes of deliverance, which, however daringly conceived and skillfully planned, were doomed to be always foiled by accident or by treachery. On such occasions he was invariably the first to come forward to shield his associates and to take the whole blame upon himself, rendering himself liable to the barbarous punishments then inflicted by the Algerines upon such of their slaves as sought to escape from their chains. Twice was Cervantes brought into the king's presence, with a rope round his neck, to be hanged. Once he was ordered two thousand blows with a stick, the penalty being remitted at the last moment only through the prayers of the other captives. The king or viceroy of Algiers at this time was Hassan Pasha, a Venetian renegade, whose name was a terror throughout Christendom. Cervantes himself in *Don Quixote* calls him "the worst of the apostate race," and "the homicide of human kind." Hædo pronounces him "the most cruel tyrant of all those who have been kings in Algiers." Over this monster, who had purchased Cervantes from Déli Mami for 1500 crowns, our hero seems to have exercised an extraordinary influence. Though repeatedly menaced with death in the most horrible forms, and condemned to witness the torture and mutilation of his companions, Cervantes never actually suffered any ill-treatment in person, beyond being fettered, nor was ever abused by an ill-word, as he himself has borne testimony in *Don Quixote*. For this exceptional immunity it is not easy to account, even on the theory that his master took him for a person of greater consequence than he really was, and we must attribute it to the extraordinary influence acquired by Cervantes over the other captives, and to the respect engendered by his magnanimity and daring. Hassan Pasha, according to Hædo,

was wont to say that "could he keep hold of that maimed Spaniard he would regard as secure his Christiaus, his ships, and his whole city." Hassan Pasha's fears were not wholly unwarranted, although the object of them was but a simple soldier, for Cervantes had conceived the design of a general rising of the captives in Algiers and the seizure of the city. "And assuredly," says Hædo, "the plan would have succeeded, and Algiers would have been Christian, if his fortune had corresponded to his courage, his zeal, or the greatness of the undertaking." From the dungeons of Hassan Pasha Cervantes wrote to Mateo Vasquez, the secretary of Philip II., suggesting the enterprise as one befitting the arms of his royal master; nor was it so desperate as might appear, seeing that the number of Christian captives in that day was nearly 25,000. Philip, however, was then too much occupied in the conquest of the Christian kingdom of Portugal to bestow any attention on the daring project of Cervantes.

In the meantime, while the captive was wasting his heart away in chains and in fruitless struggles for liberty, his friends in Spain were not neglectful of his condition. His family were too poor to be able of their own resources to raise the sum demanded by Hassan Pasha for his ransom. At the prayer of his brother Rodrigo an official investigation was held upon the conduct of Cervantes and the circumstances of his captivity, and at the solicitation of the father and mother, the Duke de Sesa wrote a strong letter to King Philip on behalf of the soldier of Lepanto, recounting his services and entreating his majesty's assistance. No other response, however, was vouchsafed to this and other petitions which were addressed to the Court by Cervantes's mother (his father being now dead), save a gracious permission to Doña Leonora, dated the 17th of January 1581, to export licensed goods from Valencia to Algiers, to the value of 2000 ducats. The profit in this venture was only 60 ducats. The widow and her daughters having raised 300 more, a sum of 500 ducats was made up with the assistance of friends, and entrusted to the hands of Father Juan Gil, the Redemptorist, who embarked for Algiers in May 1580. Hassan Pasha, however, would abate nothing of his demand, which was 1000 ducats, and threatened to take Cervantes with him to Constantinople, whither he was now recalled on the expiration of his term of government. Cervantes was actually embarked and chained to his place at the oar, when, finally, through the pious zeal of the good friar Juan Gil, aided by the liberality of some Christian merchants of Algiers, the sum required was made up. After a little delay in Algiers rendered necessary to clear himself of some false accusations made against him by his old enemy, Blanco de Paz, Cervantes had at last the joy of arriving, after a long captivity, safe and sound in his native country, landing in Spain towards the close of the year 1580.

Ransom
and return
to Spain.

The captivity in Algiers is worthy of more study than it has received from Cervantes's biographers. Not only did it turn the whole current of his life and influence all his subsequent career, but in it, as the period of his darkest adversity, may be discovered no little of the material on which his character, and even his literary work, was founded. In the hard school of an Algerine *bagnio*, amidst chains and misery and the constant sight of death in its most appalling forms, were learnt those lessons of humanity which, controlling his heroic spirit and tempering his romantic fancy, were turned to so memorable a use in *Don Quixote*. Like him of La Mancha our knight had started in his life's adventure with a mind nursed in the glowing visions of chivalry, impatient of wrong-doing, eager for the good, full of faith in manhood, and quick to believe in the ideals of honour which his imagination had

conceived. He found himself amidst a generation which cared for none of these things, confronted by the stern realities of a commonplace age, tossed about and buffeted in a world in which chivalry had become already an anachronism. There is no need for us to search for the key to the parable of *Don Quixote*, knowing the life of the author. The experience was a bitter one, such as no man of letters ever had to endure; but from the long ordeal, which ended only with his life, Cervantes emerged sweetened and strengthened. The gay courage which was the essential attribute of his nature, the dauntless good humour—

“That ever with a frolic welcome took
The thunder and the sunshine,”

had to survive even greater trials than the five years' slavery in Algiers. On his return to Spain Cervantes was destined to taste of miseries compared to which even the cruelty of Hassan Pasha was kindness. His services, his works, his sufferings, were all forgotten. His absence of five years from the scene had been long enough to erase from the memories of the king and the Court the gallant soldier who had fought and bled at Lepanto. In 1580 Philip II. was marching his army into Portugal, and Cervantes rejoined his old regiment of Figueroa, in which his brother Rodrigo was also serving. The next year we find him engaged in the expedition against the Azores, where the partizans of Dom Antonio, known to history as the Prior of Ocrato, the rival claimant to the Portuguese throne, were holding out with the assistance of England and France. On the miscarriage of this enterprize through the dissensions between the military and naval commanders, the fleet returned to Lisbon. The next year it took the sea again under the command of Don Alvaro de Bazan, Marqués de Santa Cruz, celebrated by Cervantes in *Don Quixote* as “that thunderbolt of war, that father of his soldiers, that fortunate and invincible captain.” In the victory gained by Santa Cruz over the allied squadrons off Terceira, on the 25th of July 1582—one of the most brilliant achievements in the annals of the Spanish navy—Cervantes took a part, being on board the admiral's galleon, the “San Mateo,” which bore the brunt of the fighting. It was not until the year following, however, that the Azores were finally reduced, Rodrigo Cervantes distinguishing himself greatly in the storm of Terceira. During his service and residence in Portugal, of which country and its people he ever spoke with a kindness rare among Spaniards, Cervantes had some passages of love with a noble Portuguese lady, who bore him a daughter, Isabel, his only child, the object of her father's tenderest affection and a sharer in all his troubles till his death.

Of the next few years the record is a brief one. Towards the last months of 1583 we hear of Cervantes being at Mostagan, a Spanish post on the Algerine coast, probably still with his regiment, whence he was sent with despatches to the king, by whom he was ordered to return to Oran. He does not seem to have been employed again in any official capacity, and perhaps from this time he began to despair of that military preferment to which his services had given him so just a claim. Even if it were possible for one in his station to attract the personal notice of the king, we could not expect that such a man as Philip should recognize the merit of the future author of *Don Quixote*, nor could the moroso tyrant who grudged the glory of Lepanto to his brother be particularly well disposed to one whose chief title to remembrance was his share in that victory. By the end of 1583 Cervantes appears to have quitted the profession of arms and returned to literature, being now in his thirty-sixth year. About this time he wrote *Galatea*, a prose pastoral interspersed with lyrics, inspired, according to the tradition, by love of the lady he

was then courting, and who became his wife. Dedicated to Ascanio Colonna, son of Marco Antonio of that name, Cervantes's old commander, it appears to have been favourably received, and is not more unreadable than the books of that class so happily ridiculed by Cervantes himself in the 73d chapter of the second part of *Don Quixote*. As the author himself frankly informs his readers, his “shepherds and shepherdesses are many of them only such in their dress.” Their names of Lauso, Tirsi, and Damon are but the grotesque disguises of celebrated poets of the time and friends of Cervantes—in *Galatea* being pictured his future wife and in Elisio himself. They talk high-flown sentiment and make stilted love after the manner of the school of Gil Polo in his *Diana Enamorada*, nor is their talk more insipid than is usual to the pastoral profession in fable. There is no better criticism of the book than that which Cervantes himself has given through the mouth of the priest in the scrutiny of *Don Quixote*'s library. “What book is that?” “The *Galatea* of Miguel de Cervantes,” said the barber. “’Tis many years since he has been a great friend of mine that Cervantes, and I know that he is rather versed in sorrow than in poetry. This book has some invention; it proposes something, and it concludes nothing; it behoves us to wait for the second part which he promises. Perhaps with his amendment he will obtain that entire pardon which is now denied to him; in the meantime, gossip, keep him a recluse in your chamber.” This second part never appeared, perhaps with no loss to the author's reputation. Poor as the verse is in *Galatea*, it secured for Cervantes a place among the chief poets of the age, and there is evidence to show that it was held in esteem, even out of Spain, before and after the appearance of *Don Quixote*.

On the 12th of December 1584 Cervantes added to his Marriage-happiness if not to his fortune by a marriage with Doña Catalina de Palacios Salazar y Vozmediano, a lady of good family of Esquivias. The settlement on his wife of a hundred ducats, supposed to be one-tenth of his estate, and the inventory of his effects taken at this time, among which are included “45 hens, some chickens, and a cock,” prove that the bridegroom was in but indifferent circumstances, even for a poor *hidalgo* of the time. Of the lady the records give us scarcely a glimpse, and indeed for some years after his marriage the life of Cervantes is wrapt in obscurity. All that is known is that he wrote poetry, and won many friends among the poets by his good nature and genial humour. He wrote for the stage also for a living, producing between twenty and thirty plays, chiefly comedies, of which only two survive, *La Numancia* and *El Trato de Argel*. There seems to be no reason to doubt Cervantes's own statement that as a playwright he gained considerable applause, and it has been proved that the payment he received was quite as high as that given to Lope de Vega. August Schlegel has assigned high rank to *La Numancia* as one of the most striking and original of modern tragedies, and *La Confusa*, a comedy now lost, is spoken of with much complacency by its author. The gifts of Cervantes, however, were not those of the dramatist, and such fame as he had begun to win paled before the rising star of that “monster of nature,” Lope de Vega. Once more disappointed in his hopes of a livelihood, and having now to support his wife, his widowed sister, and his natural daughter, Cervantes was forced to seek for bread by other means than literature. For twenty years—the darkest period of his life—he ceased to write, or at least to publish. The poor crippled soldier had to drink of a cup even more bitter than loss of liberty among the Moors. A veil hangs over this portion of his career, which his countrymen, for their own sake no less than for his, are not too eager to lift, hiding, as it is only too certain

that it does, penury, rags, almost beggary, misery of every kind except shame. Throughout all these trials what is known of Cervantes proves him at least to have retained undimmed his cheerfulness of spirit, his rare sweetness of disposition and faith in humanity, "as one in suffering all that suffers nothing." In 1588 he is found at Seville filling the humble place of a commissary under Don Antonio de Guevara, the Proveedor-General of the Indian fleets. In this capacity he had to assist in the victualling of the Invincible Armada, and documents preserved in the archives of Seville prove his activity in the purchase of grain, oil, and wine among the villages of Andalusia,—gleaning, besides naval stores, much of that knowledge of life and character of which he afterwards made such admirable use. In 1590 he petitioned the king for employment in the Indies, minutely recapitulating his past services, and naming four offices then vacant as those he was qualified to fill—the accountantship of New Granada, that of the galleys of Carthagena, the government of the province of Socomusco, in Guatemala, and the corregidorship of the city of La Paz. The petition was coldly received and bore no fruit, for which perhaps the ingratitude of the Government was not wholly to blame. The habits of unthrift and restlessness which he had acquired as a soldier, together with such weaknesses as were the natural defects of his virtues of extreme good nature and easiness of disposition, must have unfitted him to some extent for the sober pursuits of civil life; and Cervantes himself seems to hint, in a passage in *Don Quixote*, as well as in his *Journey to Parnassus*, at some imprudence which contributed to spoil his advancement. He continued for some years to hold his poor place of commissary, residing chiefly at Seville. At a poetical competition held at Saragossa in honour of the canonization of San Jacinto, in 1595, he was adjudged the first prize—three silver spoons. The next year, on the occasion of the sacking of Seville by the English under Essex, he wrote a sonnet, ridiculing with fine irony the behaviour of the Duke of Medina-Celi, who, having a large force at his command for the defence of the city, only appeared on the scene when the English had departed. Owing to the treachery and failure of an agent, through whom he had remitted to Madrid a sum of money, collected on account of the Government, Cervantes about this time became involved in a pecuniary difficulty, which continued to be a source of annoyance to him for some years, in addition to his other troubles. Being unable to repay the money at the king's mandate, he was cast into prison, but having succeeded in scraping together enough to reduce his debt to a few hundred reals, he was released after a few days' detention. Neither on this occasion, nor on two subsequent ones when he fell under the cognizance of the law, was there left any stain upon his honour, nor any fault alleged beyond that of carelessness or undue trustfulness. On the death of Philip II., in 1598, his obsequies were celebrated at Seville with such extravagant pomp and grandeur of decoration as to awake the ridicule of Cervantes, who, never a lover of the defunct monarch, gave vent to his feelings in a sonnet which is one of the happiest of his lighter effusions in this which was his true vein in poetry. At this period the author, in spite of his poverty and mean condition, seems to have enjoyed the society and friendship of his countrymen most famous in literature and art, among others of the celebrated poet Fernando de Herrera and the artists Pacheco and Jauregui, by both of whom his portrait was painted. He wrote and circulated in manuscript some of those novels which many years later he completed and published; but like the poor poet whom he has described, half of his divine thoughts and imaginations were taken up in the study of the means of daily bread for himself and his family.

The four years succeeding 1598 are wholly a blank in the life of Cervantes. Tradition assigns to this period the visit to La Mancha where occurred that new trouble of which *Don Quixote* is supposed to be the vengeance. The story is, that Cervantes had a commission from the prior of St John to collect his tithes in the district of Argamasilla, and that while he was employed in this ungrateful function the villagers set upon him, and after maltreating him threw him into prison, his place of imprisonment being a house still standing called *La Casa de Medrano*. Here, according to a general consensus of opinion, was conceived, if not written, the first part of *Don Quixote*, conformably to what the author says in the prologue of this "child of his wit" being "born in a gaol."

In 1603 Cervantes is found living at Valladolid, among the herd of starving soldiers and needy writers expectant of preferment which then filled the Court. The favours of Philip III., good natured and well-disposed to literature, were dispensed by the Duke de Lerma, then at the height of his power, whose haughty, cold, and selfish nature was little likely to see merit in Cervantes. Once more disappointed in his hopes of preferment, Cervantes was reduced to the utmost straits of poverty, eking out a living by business agencies and humble literary employment, such as writing petitions and correcting manuscripts, aided by such small gains as the ladies of his household were able to earn by the labours of the needle. By the beginning of 1604 he had completed the work which was destined to give him, if not bread, immortality. The First Part of *Don Quixote*, begun, according to internal evidence, before the death of Philip II., was now ready for the press. The date is the same which the majority of Shakespearian critics have assigned to the first appearance of the second and perfect *Hamlet*; nor is this the only coincidence between the lives of these two great contemporaries. A patron being in that age as necessary to an author as a publisher, Cervantes with some difficulty found one in the Duke de Bejar, a nobleman of high rank and honour, ambitious of the name of a Mæcenas. The tradition which tells how the duke's scruples at connecting his name with a book of so novel a character and equivocal a purpose were surmounted is probably well founded. Instigated, it is said, by his confessor, who scented heresy, or at least a dangerous humour, in this book with a strange name, the Duke de Bejar withdrew the promise of patronage he had given and would not accept Cervantes's dedication. The author, however, begged hard for permission to read a chapter of his story before the duke, and pleased him so well that his objections were overcome. The licence for publication was obtained on the 26th September 1604, and in the beginning of the next year the first part of *Don Quixote* was printed at Madrid by Juan de la Cuesta, and published by Francisco de Robles, to whom Cervantes had sold the copyright for ten years. The theory that the book was received coldly at first, so that Cervantes was induced to write a tract called *El Buscapie*, in order to attract the attention of the public to *Don Quixote* and to stimulate their curiosity by hinting that the characters and incidents were not wholly imaginary, must be rejected as unsupported by a title of evidence and wholly opposed to the facts. There is no proof that any such tract as *El Buscapie* ever existed until Don Adolfo de Castro published in 1848 what all competent Spanish critics have pronounced to be a clumsy and impudent forgery. There could be no reason for such a publication by Cervantes, seeing that *Don Quixote* was received by the great mass of the public with marked and singular applause. Although certain great literary personages, and some of Cervantes's own friends, from suspicion that they were included in the satire or from jealousy of his success, professed to sneer at the book because of its vulgar

Publication
of the first
part of *Don
Quixote*.

style, its unbecoming subject, and its bizarre title, there can be no doubt of the extraordinary popularity achieved by *Don Quixote* on its first appearance. No fewer than six impressions of the first edition of 1605 are extant, of which two were issued at Madrid, two at Valencia, and two at Lisbon. There had appeared up to that date no book since the invention of printing which had so many readers. To that artificial age, reared in the insipid extravagances of the successors of Amadis, *Don Quixote* was as the dawn of a new revelation. The humour, equally simple and deep, the easy, careless grace of the narrative, the fine wisdom and tenderness, the true charity, of this book which professed to be a burlesque of the romances of chivalry, were qualities as rare as they were delightful in Spanish literature. Even those who missed the allegory and were insensible to the satire could not but enjoy the story with its fresh and lively pictures of national life and character. That which has become, to use the phrase of Sainte-Beuve, "the book of humanity," was no less successful in its age as a book of popular recreation. The author himself was probably amazed at his own success. Like his great contemporary Shakespeare, while careful of his lesser works he seems to have abandoned his masterpiece to the printers with scarcely a thought of his literary reputation. All the first editions of *Don Quixote* swarm with blunders of the most extraordinary kind, proving that Cervantes could never have revised the printing, even if he had looked through his manuscript before committing it to the press. He is made to forget in one chapter what he had written in another. He confounds even the names of his characters, calling Sancho's wife Theresa in one place and Maria in another—the very blunders of which he afterwards accused his enemy Avellaneda. He makes Sancho ride his ass immediately after it had been stolen by Gines de Passamonte, and bewail its loss when it had been recovered. He confounds time, place, and persons, and abounds in inaccuracies and anachronisms, to the distraction of his readers, the perturbation of his critics, and the serious grief of his admirers. The style of this first part of *Don Quixote*, in spite of occasional passages of beauty which are among the models of the Castilian tongue, is loose, slovenly, and inartistic. Even in the second edition, published in 1608 and revised by the author, a great many patent blunders were suffered to stand, over which Cervantes himself makes merry in the second part. All this is unfavourable to the theory which some critics have formed that there was a purpose in the book other than what appears on the surface. There is no reason to doubt Cervantes's own declaration, several times repeated, that in writing *Don Quixote* he had no other design than to destroy the credit of those romances of chivalry whose reading was so pernicious to the taste and morals of the age, and to furnish "a pastime for melancholy and gloomy spirits." The idea of Byron that Cervantes "laughed Spain's chivalry away" is not more absurd than some recent conjectures that *Don Quixote* was intended as a satire upon certain leading personages of the Spanish court, especially upon the Duke de Lerma. The chivalry of Spain was already gone before Cervantes wrote. Had it not been gone *Don Quixote* would not have been written, nor would it have fallen to Cervantes, the most chivalrous of men, to deliver its death stroke. Not chivalry, but the foolish and extravagant romances of chivalry it was which Cervantes undertook to destroy; and so completely was his work done that none of them appeared after 1604. There was no man of that age more deeply imbued, as his life bears witness, with the true chivalrous spirit, nor was there any better affected, as his book shows, to all the literature of chivalry. *Don Quixote* itself is a romance of chivalry, certainly not less inspired with the

purest sentiment of honour, or furnishing a less exalted model of knighthood than Amadis of Gaul or Palmerin of England. Every passage of it proves how carefully and sympathetically Cervantes had studied his originals. For the romance of Amadis itself, as contained in the four first books of Garci-Ordoñez, Cervantes always professed a high respect. What he intended to ridicule was the continuation of Amadis in all the endless series of his descendants, each surpassing its predecessor in extravagance and folly. The theory that Cervantes wrote *Don Quixote* in order to revenge himself on the Duke de Lerma and his satellites, which has been revived in these latter days, scarcely deserves serious refutation. To those who are able to believe that in the character of the knight of La Mancha the author intended to portray his mortal enemy the more material improbabilities which surround this hypothesis will present no difficulty. In one sense *Don Quixote* is indeed a satire; but the follies it ridicules are those common to all humanity and to every age, and the satire is of that rare kind which moves not to depreciation but to love and pity of the object—to sympathy rather than to contempt, and to tears as well as laughter. *Don Quixote* and Sancho Panza are permanent types individualized. They are as true for all time as for the sixteenth century—for all the world as for Spain. The antithesis of the pure imagination without understanding and the commonplace good sense without imagination which these two represent is the eternal conflict which possesses the world. The secret of the marvellous success of *Don Quixote*, of the extraordinary popularity which makes it not only the great book of Spain but a book for all mankind, has been aptly described by Coleridge to lie in the rare combination of the permanent with the individual which the genius of the author has been enabled to achieve. *Don Quixote* is not only the perfect man of imagination, less the understanding, but he is a living picture of the Spanish *hidalgo* of the time of Philip II. Sancho is the ideal commonplace man of sense, less the imagination, and also the pure Manchegan peasant. In the carrying out of his happy conception Cervantes was doubtless careless of his own main purpose, so that this burlesque of romance has become a real picture of life—this caricature of chivalry the truest chivalric model—this life of a fool the wisest of books.

The fame acquired by the publication of the first part of *Don Quixote* does not appear to have contributed materially to the improvement of the author's fortunes. In 1605 he was still living at Valladolid, where, with his usual ill-luck, he was involved in a painful incident which brought him once more, though perfectly innocent, into collision with the authorities. A young nobleman of the court, being wounded in a street brawl, was carried into the house where Cervantes lodged to be tended, and died there of his hurts. Cervantes and his family, with the other inmates of the house, were cast into prison, according to the rough process of Spanish law, until they could be examined before the alcalde. From the depositions of the witnesses, which are extant, we learn that at this time Cervantes's household consisted of his wife, his natural daughter Isabel, over 20 years old, his widowed sister Andrea, with her daughter Constanza, and another sister, Magdalena, with one female servant; and that he made his living by writing and general agency. In May of this year there arrived at Madrid the earl of Huntingdon with a retinue of 600 persons from England, bearing a message of congratulation to the king on the birth of his heir, afterwards Philip IV., on which occasion were given a series of magnificent entertainments. On the strength of an allusion in a satirical sonnet by Gongora, a narrative of the festivities, published in 1605 and still extant, has been attributed to Cervantes, but it bears no marks of his style, and it

been printed, either in the original or in translation, thus realizing the author's prediction that there would be no nation or language to which his book would not be carried. According to the interesting story told by the archbishop of Toledo's secretary, in his approbation appended to the second part, dated February 1615, foreigners of distinction, when they visited Madrid, made it their first business to enquire after the author of *Don Quixote*. To a party of French gentlemen, members of the suite of the ambassador, the Duc de Mayenne, who were anxious to learn of the condition and mode of life of the celebrated writer, the secretary of the archbishop was obliged to respond that "he who had made all the world rich was poor and infirm, though a soldier and a gentleman." The man who was the delight of his age and destined to be the chief glory of his country was indeed still in great misery, depending on alms for his subsistence, and now in his sixty-ninth year stricken by a mortal disease. In the dedication of his second part of *Don Quixote* to the Count de Lemos, Cervantes speaks of his broken health and approaching end, still with unabated courage and cheerfulness. His last work, not published till after his death, was *Pericles and Sigismunda*, a romance of love and adventure after the model of Heliodorus, on which he bestowed great pains and singular affection, declaring that it would be either the best or the worst of his books. The dedication to the Count de Lemos is written with an astonishing gaiety and spirit, though it announces that the author had yesterday received extreme unction, and had "one foot in the stirrups," waiting for a summons. About this time must have occurred that adventure, which is so pleasantly told in the prologue, of the meeting with the student near Toledo, when our author, in a grievous state from dropsy, was returning from a visit to his wife's family at Esquivias, at the close of which he wrote:—"And so farewell, humours; farewell, my gay friends, for I feel myself dying, and have no desire but soon to see you happy in the other world." On the 4th of April he entered the order of the Franciscan Friars, whose habit, following the fashion of the period, he had assumed three years before, and on the 23d of that month he ended, in all serenity and cheerfulness, his life of many troubles. In the same year, and nominally on the same day, though really ten days later, allowance being made for the difference of calendars, died William Shakespeare in England. Cervantes's body was buried humbly at the expense of his religious order in the convent of the Trinitarian Nuns in the Calle de Humilladero, of which community his daughter Isabel was a professed member. In 1633 the nuns moved to a new site in the Calle de Cantarrenas, and having exhumed and brought away their dead with them, the bones of Cervantes were mingled with others in a common ossuary, so that Spain, who had shown herself so careless of him in life, has lost all trace of him in death. So closes a record as glorious and as calamitous as any in literary history, of one of the world's greatest benefactors, whom the world knew not—of the best of all Spaniards, the very type and perfect embodiment of the highest Castilian nature, whom his country starved and who has made her immortal.

The language of eulogy has been exhausted over that work of Miguel de Cervantes which for two hundred and fifty years has been the delight of mankind in a degree such as no other book has ever approached. There is nothing to add to the tribute which the critics of all countries have joined in paying to the wisest, tenderest, and deepest of humourists.

The popularity of *Don Quixote* is best attested by the extraordinary number of editions and translations which have appeared in all languages. According to a computation made by Don Lope de Fabra, in his appendix to the Barcelona fac-simile of the first edition, there were published, up to 1874, 278 editions of *Don Quixote*, of

which 87 appeared in Spain, and 191 in other countries. Of these, 136 are in the original. Translations have appeared in English, French, German, Dutch, Italian, Danish, and indeed in every European tongue, including Turkish. England, who of all foreign nations has ever been foremost in recognizing the genius of Cervantes, is entitled to the honour of having produced the first critical edition of the Spanish text, which is that of Dr John Bowle, published at Salisbury in 1781. This has served as the basis of all the subsequent Spanish editions; for although the Royal Academy anticipated Bowle by a year in its magnificent edition printed by Ibarra, it was a knowledge of the Englishman's design, and to some extent of his labours, which prompted that undertaking. The other most important critical editions in Spanish are that of Pellicer, published in 1797, who has borrowed largely, and not with due acknowledgment, from Bowle; that of Clemencin, in 1833-39, with a very elaborate commentary, displaying much industry and learning but little taste or sympathy, and sadly lacking in reverence for the author; and that in the complete edition of Cervantes's works printed at Argamasilla in 1864, under the editorship of Don Eugenio de Hartzenbusch and Don Cayetano Alberto de Rosell,—superb in type and paper, but otherwise of little value, with a text disfigured by wanton emendations. The principal English translations are—the first, by Thomas Shelton, which is also the earliest version of *Don Quixote* in any foreign language, published in 1612-20, vigorous, and of a spirit akin to the original, but rude and incorrect; that of Motteux, absurdly over-praised by Lockhart, which is nothing more than a loose paraphrase of Cervantes's text, in a style consciously comic and therefore of all the most unhappy for *Don Quixote*; that of Jarvis, which, with some trifling revisions, is the current accepted version—correct and careful, but dull, commonplace, and destitute of humour; and that of Smollett, which is the worst of all, being a piece of hack-work done for the booksellers, without knowledge of Spanish, or even such an insight into his author's meaning as his kindred genius should have suggested. By far the best life of Cervantes is that by Don Martín Fernandez de Navarrete, published in Madrid in 1819. (H. E. W.)

CERVIA, an episcopal town of Italy, with a port on the Adriatic, in the district of Ravenna, and 12 miles S.E. of the city of that name. In the vicinity are the extensive salt-works of Valle di Cervia. Population about 5700.

CESARI, GIUSEPPE, called Il Cavaliere d'Arpino (being born in or about 1568 at Arpino, and created a "Cavaliere di Cristo" by Pope Clement VIII.), also named Il Giuseppino, an Italian painter, much encouraged at Rome and munificently rewarded. Cesari is stigmatized by Lanzi as not less the corrupter of taste in painting than Marino was in poetry; indeed, another of the nicknames of Cesari is "Il Marino de' Pittori" (the pictorial Marino). There was spirit in Cesari's heads of men and horses, and his frescoes in the Capitol (story of Romulus and Remus, &c.), which occupied him at intervals during forty years, are well coloured; but he drew the human form ill. His perspective is faulty, his extremities monotonous, and his chiaroscuro defective. He died in 1640, at the age of seventy-two, or perhaps of eighty, at Rome. Cesari ranks as the head of the "Idealists" of his period, as opposed to the "Naturalists," of whom Michaelangelo da Caravaggio was the leading champion,—the so-called "idealism" consisting more in reckless facility, and disregard of the common facts and common-sense of nature, than in anything to which so lofty a name could be properly accorded. He was a man of touchy and irascible character, and rose from penury to the height of opulence.

CESAROTTI, MELCHIORE (1730-1808), an Italian poet, born at Padua in 1730, of a noble but impoverished family. At the university of his native place his literary progress procured for him at a very early age the chair of rhetoric, and in 1768 the professorship of Greek and Hebrew. On the invasion of Italy by the French, he gave his pen to their cause, received a pension, and was made knight of the iron crown by Napoleon I., to whom, in consequence, he addressed a bombastic and extravagantly flattering poem called *Pronea*. Cesarotti is best known as the translator of Homer and Ossian. Much praise cannot be given to his version of the *Iliad*, for he has not scrupled to add, omit, and modernize. Ossian, which he held to be the finest of poems, he has, on the

other hand, considerably improved in translation; and the appearance of his version attracted much attention in Italy and France, and raised up many imitators of the Ossianic style. Cesarotti also produced a number of works in prose, including a *Course of Greek Literature*, and essays *On the Origin and Progress of the Poetic Art*, *On the sources of the Pleasure derived from Tragedy*, *On the Philosophy of Language*, and *On the Philosophy of Taste*, the last being a defence of his own great eccentricities in criticism. His style is forcible but full of Gallicisms, and he is too fond of novelty both in expression and matter. A complete edition of his works, in 42 vols. 8vo, began to appear at Pisa in 1800, and was completed in 1813 after his death. See *Memoirs* by Barbieri (Padua, 1810).

CESENA (Lat. *Cæsena*, or *Casenia*), an episcopal city of Emilia, in the province of Forlì, a station on the railroad between Bologna and Ancona, gives its name to a "circondario" and to two subdivisions or "mandamenti" of the same. Population of circondario in 1862, 77,489. A very fertile region, it makes good white wine of some reputation, rears silk-worms to some extent, and has some sulphur mines, lignite, and specially good brick clay; but its principal source of wealth is its hemp, deemed the best in the north of Italy. The city (15 miles E. of Forlì, 25 N. of Rimini, 17½ S. of Ravenna) has 7777 inhabitants, and lies where the Apennine melts into the plain, at the foot of the Monte Garano, on which once stood the ancient cathedral, replaced by another of debased Gothic architecture, built in the 15th century, in which are some works of Donatello. On the hill above the city are also the imposing ruins of the castle, believed to have been built by the Emperor Frederick II. The famous sanctuary of Madonna del Monte, with its church by Bramante, is also a prominent object in the landscape. The town, irregularly but well built, and divided by the little river Cesola, has several interesting buildings. The town hall is of good mediæval architecture, and possesses a very fine Francia, a Sassoferrato, and some other interesting pictures. Cesena has a large and handsome theatre, some fine palaces of the provincial noble families, and a cemetery of which it is specially proud,—one of the handsomest and best ordered in Italy. The little city has an interesting history of its own, full of eventful changes. It fell in the 4th century under the tyranny of the Malatesta family, one of the worst races of the Italian mediæval tyrants. But it was perpetually rebelling, and occasionally recovering its liberty and autonomy. Dante, in the 27th canto of the *Inferno*, characterizes Cesena as living midway between tyranny and freedom, even as she is placed physically between the mountains and the plain. In 1859 Cesena was among the first of the cities of the Romagna which threw off the Papal yoke.

CESPEDES (in Italian **CEDASPE**), **PABLO DE** (1538–1608), was born at Cordova, and was educated at Alcalá de Henares, where he studied theology and Oriental languages. On leaving the university, he went to Rome, where he became the pupil and friend of Federigo Zuccheri, under whose direction he studied particularly the works of Raphael and of Michelangelo. In 1560, while yet in Rome, proceedings were taken against him by the Inquisition at Valladolid on account of a letter which, found among the papers of the archbishop of Toledo, had been written by Cespedes during the preceding year, and in which he had spoken with great freedom against the holy office and the inquisitor-general, Fernando de Valdés. Cespedes remained in Rome at this critical moment, and from which city he appears rightly to have treated this matter of the prosecution with derision. It is not known how he contrived to bring the proceedings to an end; he returned, however, to Spain a little before 1577, and in that year was installed

in a prebend of the cathedral at Cordova, he resided till his death.

A distinguished poet, a remarkable painter, eminent also as an architect and sculptor, Pablo de Cespedes has been called the most *savant* of Spanish artists. According to his friend Francisco Pacheco, to whom posterity is indebted for the preservation of all of Cespedes's verse that is extant, the school of Seville owes to him its introduction to the practice of chiaroscuro. He was a bold and correct draughtsman, a skilful anatomist, a master of colour and composition; and the influence he exerted to the advantage of early Spanish art was considerable. Cristobal de Vera, Juan de Peñalosa, and Zambrano were among his pupils. His best picture is a Last Supper at Cordova; but there are good examples of his work at Seville and at Madrid.

Cespedes was author of several opuscles in prose on subjects connected with his profession. Of his poem on *The Art of Painting* enough was preserved by Pacheco to enable us to form an opinion of the whole. It is esteemed the best didactic verse in Spanish; Marchena and Castro compare it, not disadvantageously, with the *Georgics*. It is written in strong and sonorous octaves, in the majestic declamatory vein of Fernando Herrera, and is not altogether so dull and lifeless as is most didactic verse. It contains a glowing eulogy of Michelangelo, and some excellent advice to young painters, insisting particularly on hard work and on the study of nature. The few fragments yet remaining, amounting in all to some six hundred lines, were first printed by Pacheco in his treatise *Del Arte de la Pintura*, in 1649.

CETACEA (from the Greek word *κῆτος*, a whale) is the name employed by zoologists to characterize the important order of Mammals which contains the whales and dolphins. These mammals are aquatic in their habits, and possess a fish-like form. They differ from fishes in breathing by lungs and not by gills, in being viviparous and not oviparous, and in suckling their young with a pair of milk-secreting glands or mammae. This order was formerly divided into two groups, the herbivorous cetacea and the carnivorous cetacea. By modern zoologists the herbivorous cetacea, which include the animals called dugong, manatee, and rytina, are not regarded as whales, but are referred to a distinct order named *Sirenia*. The order *Cetacea*, therefore, in its present acceptation is limited to the toothed whales or *Odontoceti* and the whalebone whales or *Mystacoceti*. For the organization, classification, and distribution of these animals, see **MAMMALIA**.

CETINA, **GUTIERRE DE**, soldier and poet, was born at Seville during the earlier years of the 16th century. Choosing the career of arms as a means of obtaining the preferment he needed, he served several campaigns in Italy, fought at the league of Tunis (1535) against Barbarossa, and continued in the practice of his profession for some years in Flanders, under Ferdinand of Austria. The death of the prince of Aseoli, his patron and protector, whom he mourned in a fine elegiac sonnet, and his own continued poverty, would seem to have disgusted him with the trade of war. He returned to Seville, departing thence soon afterwards for Mexico, where he had a brother high in office. No more is known of him, saving that he came back again to the city of his birth, and that he died there, it is supposed about 1560. An enthusiast in art, the friend of Boscan and Garcilaso, of Hurtado de Mendoza and Jeronimo de Urrea, Gutierre de Cetina, as may naturally be inferred, followed in the wake of these poets, renouncing the old Castilian creed, and preaching the new evangel of Petrarch. His poems, which were not published till long after his death, consist of sonnets, *canzoni*, epistles in *terza rima*, and madrigals, and are remarkable for elegance and simplicity of form, and for grace and tenderness of thought

and feeling. Their author has been often confounded with Doctor Gutierre de Cetina, who was vicar of Madrid. See Rivadaneira's *Biblioteca*, vol. xxxii.

CETTE, a fortified seaport in the department of Hérault, in 43° 23' 48" N. lat. and 3° 42' 15" E. long., and 15 miles S.W. of Montpellier. After Marseilles it is the principal commercial port on the south coast of France. It occupies the foot and slope of a hill, the ancient *Mons Setius*, situated on a tongue of land that lies between the Mediterranean and the Lagoon of Thau. The town is well built, and has numerous factories, glass-works, shipbuilding yards, a custom-house, a school of navigation, a communal college, a botanic garden, museums, a library, and a theatre. It is much resorted to for sea-bathing. The harbour is capable of accommodating 400 sea-going vessels, and is safe in all weathers. The left of the two moles which form it runs E.N.E. for a distance of about 630 yards into the sea, and is then continued in a breakwater, which extends across the entrance. At the end of this mole are the fort of St Louis and the lighthouse. Opposite to them, on the other side of the harbour, is the fort of St Pierre, which, with the citadel, completes the defences of Cette. The town is connected with Lyons by the Canals des Etangs and de Beaucaire and the Rhone, and with Bordeaux by the Canal du Midi; railways communicate with Toulouse and Montpellier, and steamers with the Mediterranean ports. The shipping trade of Cette is very considerable. Its imports are colonial produce, wool and cotton, hides, cork, brandy and wine for manufacture, iron and lead ores, staves from the Adriatic, asphalt, fruits, sulphur, wheat, oats, maize, barley, timber, and coal. In 1873 the port was visited by 63 British ships, of total tonnage 17,409, mostly laden with pitch for manufacture into patent fuel at the coal mines N. of Nîmes. The greater number of these ships left Cette in ballast. The exports are wines, brandy, liqueurs, argol, verdigris, corks, salt, oil, dried fruits and fish, meal, cloth, and woollen stuffs. The sum total of imports and exports in 1870 was about 460,000 tons. In the same year 2075 ships entered, and 2108 left the port. There are upwards of 40 sailing-vessels belonging to the port, of from 60 to 300 tons burden. A large number of small craft are employed in the sardine, cod, and oyster fisheries on the coast. There are factories for the manufacture of syrups, grape-sugar, corks, soaps, and chemicals, which with the docks, the extensive salt-works in the neighbourhood, and the establishments for the making, from French and Spanish wine and brandy, of claret, sherry, port, champagne, &c., give employment to thousands. The town was founded in 1666 by Louis XIV. Population in 1872, 25,181.

CETTINJE, CETINJE, ZETINJE, CETTIGNO, or CETTIN, the capital of the principality of Montenegro, is situated on the left of a small river in a narrow plain deeply sunk in the heart of the mountains, at a height of 2470 feet above the sea. It consists of two streets of whitewashed stone houses, and, according to Mr Tozer, has very much the appearance of a Dartmoor village. The principal buildings are the monastery and the palace. The former was founded in 1478, but has been frequently burned and restored. It is surrounded with walls, and now contains a prison, a school, a library, a printing establishment, and the residences of the archimandrite and the bishop. The chapel is held in great veneration as the burial-place of the sainted Peter I. and Danilo. The palace is a comparatively simple building of two stories, composing two sides of a court, which is completed by high walls. The town owes its origin to Ivan the Black, who was obliged, in the end of the 15th century, to withdraw from Jabliak, the former capital, situated to the north of Lake Scodra. The town has frequently been taken and ravaged by the Turks,

but has seldom continued for any length of time in their possession. Population about 700.

CEUTA, or (in the local Moorish form) SEBTA, a town and fortress belonging to Spain on the coast of Morocco, on a peninsula opposite Gibraltar, in 35° 54' N. lat., 5° 18' W. long. It derives its name from its seven hills, the most important of which, the Monte del Hacho (the ancient *Abyla*, one of the pillars of Hercules), has a considerable elevation. The town is well built, and is chiefly important as a military and convict station. It contains a cathedral, the bishop of which is suffragan to the archbishop of Seville, several religious houses, and a hospital. It has a small harbour, and imports provisions and military stores from Spain. Ceuta occupies the site of the Roman colony of *Ad Septem Fratres*. In 618 the town, which had been refortified by Justinian, fell into the hands of the West Goths; and in the 8th century it was the seat of that Count Julian whose name is inseparably connected with the Saracenic conquest of Spain. Under the Arabic government it was an industrial city, and it is said to have been the first place in Western Europe where a paper manufactory was established. It was taken from the Moors by John I., king of Portugal, in 1415, and passed into the hands of the Spaniards on the subjugation of Portugal by Philip II. in 1580. It has been several times unsuccessfully besieged by the Moors—from 1694 to 1727 by Mulai Ismail, and in 1732 by Ripperda. In 1810 it was held by the English under Fraser. In 1860 the Spanish territory around the town was extended by force of arms. Population about 7000.

CEVA, the ancient *Ceba*, a town of Italy, in the province of Cuneo and 11 miles east of Mondovì, at the confluence of the Cevetta with the Tanaro. It was formerly fortified; and the rock, at the foot of which the town lies, was surmounted by a citadel. It has iron-works and silk-factories, and carries on a considerable trade in its cheese, which was famous even in the time of the Romans. In the Middle Ages it was the centre of a separate marquisate, and during the 16th and 17th centuries it was several times captured by the French and the Spaniards. In 1796 it was taken by Augereau, and in 1800, after having withstood the siege of the previous year, it again fell into the hands of the French. The conquerors destroyed the castle, which had served as a state prison. Population, 4730.

CEVENNES, a mountain chain in the south of France, dividing the valleys of the Lower Saône and Rhone from those of the Loire and the Garonne. On the N. the Cévennes are a continuation of the Lyonnais mountains; and they end on the S. at the Canal du Midi, which separates them from the Pyrenees. They are divided into two parts,—the south consisting of the Montagnes Noires (in Aude and Hérault), the Espinouses (in Tarn, Aveyron, and Hérault), the Garrigues (in Aveyron and Gard), and the Cévennes proper or Lozère or Gévaudan (in Lozère); and the north consisting of the Vivarais (in Ardèche). Sometimes there are also included in the name the Lyonnais (in Rhône) and the Charolais (in Saône-et-Loire). The average height is 3000 to 4000 feet; and the highest peaks are Mount Mezenc (in Ardèche), 5788 feet, and Mount Lozère, 4880. The principal rivers which take their rise in these mountains are the Loire, the Allier, the Lot, and the Tarn. The mountains consist of limestone, greywacke, and granite; and beds of trachyte and lava give evidence of former volcanic action. In the Cévennes are found iron, coal, lead, silver, copper, antimony, marble, and porphyry. The lower slopes are well cultivated; higher up good pasturage is found; while the summits are generally covered with forests of chestnut and pine. The Cévennes are famous as the retreats of the Albigenses, Waldenses, and Camisards.

CEYLON

CEYLON, an island in the Indian Ocean, separated on the N.W. from continental India by the Gulf of Manaar. It lies between $5^{\circ} 55'$ and $9^{\circ} 51'$ N. lat., and between $79^{\circ} 41' 40''$ and $81^{\circ} 54' 50''$ E. long. Its extreme length from north to south is 271 miles; its greatest width

Sketch Map of Ceylon (embracing 299 miles by 233).

is 137 miles; and its area, including that of its dependent islands, amounts to 25,742 miles, or about one-sixth smaller than Ireland. In its general outline the island resembles a cone, the apex of which points towards the north.

The Coast.—The coast is beset on the N.W. with numberless sandbanks, rocks, and shoals, and may be said to be almost connected with India by the island of Ramisseram and Adam's Bridge, a succession of bold rocks reaching almost across the gulf at its narrowest point. Between the island and the opposite coast there exist two open channels of varying depth and width, beset by rocks and shoals. One of these, the Mannar Passage, is only navigable by very small craft. The other, called the Paumben Passage, lying between Ramisseram and the mainland, has been deepened at considerable outlay, and is now used by vessels drawing ten feet of water, in passing from the Malabar to the Coromandel coast, which were formerly compelled in doing so to make the circuit of the island. The west and south coasts, which are uniformly low, are fringed their entire length by cocoa-nut trees, which grow to the water's edge in great luxuriance, and give to the island a most picturesque appearance. Along these shores there are numerous inlets and backwaters of the sea, some of which are available as harbours for small native craft. The east coast from Point de Galle to Trincomalee is of an entirely opposite character, wanting the ample vegetation of the other, and being at the same time of a bold precipitous character. The largest ships may freely approach this

side of the island, provided they take care to avoid a few dangerous rocks, whose localities are, however, well known to navigators.

Seen from a distance at sea, this "utmost Indian isle" of the old geographers wears a truly beautiful appearance. The remarkable elevation known as "Adam's Peak," the most prominent, though not the loftiest, of the hilly ranges of the interior, towers like a mountain monarch amongst an assemblage of picturesque hills, and is a sure landmark for the weary navigator, when as yet the Colombo lighthouse is hidden from sight amidst the green groves of palms that seem to be springing from the waters of the ocean.

The low coast-line of country encircles the mountain-zone of the interior on the east, south, and west, forming a belt which extends inland to a varying distance of from 30 to 80 miles; but on the north the whole breadth of the island from Kalpitiya to Batticaloa is an almost unbroken plain, containing magnificent forests of great extent.

Mountains.—The mountain zone is towards the south of the island, and covers an area of about 4212 miles. The uplifting force seems to have been exerted from south-west to north-east, and although there is much confusion in many of the intersecting ridges, and spurs of great size and extent are sent off in many directions, the lower ranges manifest a remarkable tendency to run in parallel ridges in a direction from south-east to north-west. Towards the north the off-sets of the mountain system radiate to short distances and speedily sink to the level of the plain. Detached hills are rare; the most celebrated of these are Mihintale, which overlooks the sacred city of Anuradhapura, and Sigiri. The latter is the only example in Ceylon of those solitary acclivities which form so remarkable a feature in the table-land of the Deccan,—which, starting abruptly from the plain, with steep and perpendicular sides, are frequently converted into strongholds accessible only by precipitous pathways or by steps hewn in the solid rock.

For a long period Adam's Peak was supposed to be the highest mountain in Ceylon, but actual survey makes it only 7352 feet above the sea-level. This elevation is chiefly remarkable as the resort of pilgrims from all parts of the East. The hollow in the lofty rock that crowns the summit is said by the Brahmans to be the footstep of Siva, by the Buddhists of Buddha, by the Mahometans of Adam, whilst the Portuguese Christians were divided between the conflicting claims of St Thomas and the eunuch of Candace queen of Ethiopia. The footstep is covered by a handsome roof, and is guarded by the priests of a rich monastery half way up the mountain, who maintain a shrine on the summit of the peak. The highest mountains in Ceylon are Piduru Talagala, 8295 feet in altitude; Kirigalpota, 7836 feet; and Totapelakanda, 7746 feet.

The summits of the highest ridges are clothed with verdure, and along their base, in the beautiful valleys which intersect them in every direction, the slopes were till within the last few years covered with forests of gigantic and valuable trees, which have now disappeared under the axe of the planter, who has felled and burnt the timber on all the finest slopes at an elevation of 2000 to 4500 feet, and converted the hill sides into highly-cultivated coffee estates. The plain of Nuwara Eliya, the sanatorium of the island, is at an elevation of 6200 feet and possesses many of the attributes of an alpine country. The climate

of the Horton plains, at an elevation of 7000 feet, is still finer than that of Nuwara Eliya, but they are difficult of access, and are but little known to Europeans. The town of Kandy, in the Central Province, formerly the capital of the native sovereigns of the interior, is situated 1727 feet above sea-level.

Rivers.—The island, though completely within the influence of oceanic evaporation, and possessing an elevated tableland of considerable extent, does not boast of any rivers of great volume. The rains which usher in each monsoon or change of season are indeed heavy, and during their fall swell the streams to torrents and impetuous rivers. But when these cease the water-courses fall back to their original state, and there are but few of the rivers which cannot be passed on horseback. "In the plains there are comparatively few rivulets or running streams; the rivers there flow in almost solitary lines to the sea; and the beds of their minor affluents serve only to conduct to them the torrents which descend at the change of each monsoon, their channels at other times being exhausted and dry. But in their course through the hills and the broken ground at their base they are supplied by numerous feeders, which convey to them the frequent showers that fall in these high altitudes. Hence their tracks are through some of the noblest scenery in the world; rushing through ravines and glens, and falling over precipitous rocks in the depths of wooded valleys, they exhibit a succession of rapids, cataracts, and torrents, unsurpassed in magnificence and beauty. On reaching the plains, the boldness of their march and the graceful outline of their sweep are indicative of the little obstruction opposed by the sandy and porous soil through which they flow. Throughout their entire course dense forests shade their banks." The most important of the Ceylon rivers is the Mahaveli-ganga, which has its source in the Pidurutalagala mountain, whence it takes a tortuous course through the Kotmale valley to Pasbage, where it is joined by a smaller branch issuing from the base of Adam's Peak; it then passes through the village of Peradeniya, where it is crossed by the railway bridge, and by a beautiful bridge, of a single span of 205 feet, constructed of satin wood, on the American or wedge principle. Thence it winds to the west and north of Kandy, and after an easterly descent of nearly 1000 feet between Kandy and Bintenne, sweeps suddenly to the north, and takes its course through the wild and open country, separating into two branches,—the smaller of which, the Verukal, enters the sea about 25 miles south of Trincomalee, while the larger, retaining its original name, falls into the great bay of Kottiar, near the noble harbour of Trincomalee, after a course of nearly 200 miles. In flood-time it rises 25 or 30 feet, but for the greater part of the year it is fordable in many places. It is seldom wider than the Thames at Richmond, and is generally of much less width. Surveys have shown that, at some outlay, this river might be made navigable for a distance of 80 or 90 miles from the sea. The upper half of its course is through a rocky and precipitous country, but the lower half is through a fine open region, well watered throughout the whole of the year, and only requiring capital and labour to convert it into the garden of Ceylon, which it once doubtless was. The remains of stupendous dams and canals bear witness to the importance which the ancient rulers of Ceylon attached to this portion of their possessions. The Kelani-ganga rises at the base of Adam's Peak, whence, running first north and then almost due west to Ruwanwella, it takes its way more southerly to Colombo, on the northern outskirts of which it falls into the sea across a wide sand-bank. It is navigable for about 40 miles by flat-bottomed boats. The Kalu-ganga and the Walawe-ganga (or Waloya) flow from the eastern base of Adam's Peak through

the district of Sabaragamuwa to the sea, the former south-westerly, the latter south-easterly. Both are navigable by country boats for some distance,—the Kalu-ganga for upwards of 50 miles, from above Ratnapura to the sea at Kalutara, whence a canal connects it with Colombo. The Walawe ganga falls into the sea 8 miles to the west of Hambantota. The Mahaoya falls into the sea, after a westerly course of about 70 miles, to the north of Negombo. The other rivers, except during the heavy rains, are of no great size, and none of them are navigable.

Lakes and Canals.—There are in Ceylon some lakes of considerable extent and of great beauty. Those of Colombo, Bolgoda, and Negombo are of natural formation; those which have been formed by human labour will be noticed below in connection with irrigation. The rivers, as already explained, descend rapidly from the hills, and sweep along in their rapid course large quantities of earthy matter; at their junction with the ocean they are met "transversely by the gulf-streams, and the sand and soil with which they are laden, instead of being carried out to sea, are heaped up in bars along the shores, and then, augmented by similar deposits held in suspension by the currents, soon extend to north and south; and force the rivers to flow behind them in search of a new outlet." At the mouths of the rivers, the bars thus created generally follow the direction of the current, and long embankments are gradually raised, behind which the rivers flow for considerable distances before entering the sea. Occasionally the embouchures become closed by the accumulations without, and the rivers, swollen by the rains, force new openings for themselves, and leave their ancient channels converted into lakes. Thus have been formed the lakes of Colombo and Negombo on the west coast, the harbour of Batticaloa on the east, and the long low embankments of sand on both coasts. These embankments, known by the local name of "Gobbs," and often from one to three miles in breadth, are covered with thriving cocoa-nut plantations.

The Dutch whilst in possession of Ceylon did much to improve its water communication, and connected the natural channels formed by these embankments by constructing artificial canals, so as to provide unbroken water communication between Kalpitiya, on the N.W. coast, and Negombo; this line has been extended from Negombo to Colombo, and on to the south as far as Kalutara.

Harbours.—The magnificent basin of Trincomalee, situated on the east coast of Ceylon, is perhaps unsurpassed in extent, security, and beauty by any haven in the world. The Admiralty has a dockyard here, and it is the principal naval station in the Indian Seas; but it is far removed from the productive districts, the population is small and scattered, and vessels have to resort to the rocky and dangerous harbour of Point de Galle at the south, or to the open roadstead of Colombo on the west. Something has been done by blasting to improve Galle harbour, but it is small, and its entrance is narrow and difficult; it is also somewhat remote from the most productive districts, and the Colonial Government has decided on making a break-water at Colombo in preference to improving Galle harbour. The anchorage at Colombo is good, and it is anticipated that the new works will render it a secure harbour at all times of the year.

Seasons, Climate, &c.—The seasons in Ceylon differ very slightly from those prevailing along the coasts of the Indian peninsula. The two distinctive monsoons of the year are called, from the winds which accompany them, the south-west and the north-east. The former is very regular in its approach, and may be looked for along the S.W. coast between the 10th and 20th of May; the latter reaches the N.E. coast between the end of October and the middle of November. There is a striking contrast in the influence

which the south-west monsoon exerts on the one side of the island and on the other. The clouds are driven against the lofty mountains that overhang the western and southern coasts, and their condensed vapours descend there in copious showers. But the rains do not reach the opposite side of the island: whilst the south-west is deluged, the east and north are sometimes exhausted with dryness; and it not unfrequently happens that different sides of the same mountain present at the same moment the opposite extremes of drought and moisture. The influence of the

north-east monsoon is more general. The mountains which face the north-east are lower and more remote from the sea than those on the south-west; the clouds are carried further inland, and it rains simultaneously on both sides of the island. Owing to the efforts of Lieut.-Col. Fyers, R.E., the surveyor-general of Ceylon, very accurate meteorological observations have been recorded throughout Ceylon for the last few years, and the following table has been compiled from the official return of rainfall in Ceylon during the years 1870-1874 inclusive:—

Months.	Colombo, 42 feet.		Galle, 40 feet.		Ratnapura, 114 feet.		Jaffna, 9 feet.		Puttalam, 11 feet.		Anuradhapura, 312 ft.		Trincomelee, 175 feet.		Kandy, 1713 feet.		Badulla, 2220 feet.		Nuwara Eliya, 6210 feet.		Kotmale, 4060 feet.

* 2 days in 1872 and 1 in 1873.

This table shows that throughout Ceylon the greatest quantity of rain falls in the last three months of the year, though at high elevations and within the immediate influence of the highest mountains the rainfall in June is very great. At Colombo, on the west coast, the rainfall is 75.70 inches, and the number of rainy days in 148; at Galle, at the south-west corner, the rainfall is nearly the same, viz., 75.31, but the number of rainy days is 195. At Ratnapura, about 65 miles S.E. of Colombo, and lying immediately under Adam's Peak, the rainfall is 146.26, and the rainy days 228. Jaffna is at the extreme north of the island; Puttalam lies on a salt lake, behind a gabb, close to the west coast. Anuradhapura lies to the north-east of Puttalam, about 40 miles from the low hills at the north of the mountain zone. Trincomelee is on the east coast, almost due east of Anuradhapura. Badulla lies to the far east of the mountain zone, and, though at a higher elevation than Kandy, has a very small rainfall. The hill-station of Nuwara Eliya has a rainfall of 96.66, and the coffee district of Kotmale, lying below the highest hills, has a rainfall of 104.22, and 182 rainy days. The returns for 1874 show that at four stations the rainfall in 24 hours exceeded five inches. The following table, compiled from the surveyor-general's returns, shows the temperature:—

Temperature of the Air in 1874.

Station.	Height above Sea.	Mean daily maximum temperature in the shade.	Mean daily minimum temperature in the shade.	Adopted mean temperature of the air.	Maximum temperature of the air.	Minimum temperature of the air.	Range.	Maximum temperature in the sun.	Minimum temperature on the grass.

The length of the day, owing to the proximity of the island to the equator, does not vary more than an hour at any season. The mean time of the rising of the sun's centre at Colombo on February 1st is 6^h 23^m A.M., and of its setting 6^h 5^m P.M. On August 15th its rising is at 5^h 45^m A.M., and its setting at 6^h 7^m P.M. It is mid-day in Colombo when it is morning in England. Colombo is situated in 79° 50' 45" E. long., and the day is further advanced there than at Greenwich by 5^h 19^m 23^s.

Geology and Minerals.—Ceylon may be said to have been for ages slowly rising from the sea, as appears from the terraces abounding in marine shells, which occur in situations far above high-water mark, and at some miles distance from the sea. A great portion of the north of the island may be regarded as the joint production of the coral polypi and the currents, which for the greater part of the year set impetuously towards the south; coming laden with alluvial matter collected along the coast of Coromandel, and meeting with obstacles south of Point Calimere, they have deposited their burdens on the coral reefs round Point Pedro; and these, raised above the sea-level, and covered deeply by sand drifts, have formed the peninsula of Jaffna, and the plains that trend westward till they unite with the narrow causeway of Adam's Bridge. The Tertiary rocks are almost unknown. The great geological feature of the island is the profusion of gneiss, overlaid in many places in the interior by extensive beds of dolomitic limestone. This formation appears to be of great thickness; and when, as is not often the case, the under-surface of the gneiss series is exposed, it is invariably found resting on granite. Veins of pure quartz and felspar of considerable extent have been frequently met with in the gneiss; whilst in the elevated lands of the interior in the Galle districts may be seen copious deposits of disintegrated felspar, or kaolin, commonly known as porcelain clay. At various elevations the gneiss may be found intersected by veins of trap rocks, upheaved whilst in a state of fusion subsequent to the consolidation of the

former. In some localities on the sea-shore these veins assume the character of pitch-stone porphyry highly impregnated with iron. Hornblende and primitive greenstone are found in the vicinity of Adam's Peak and in the Pussellava district.

Laterite, known in Ceylon as *cabook*, a product of disintegrated gneiss, exists in vast quantities in many parts, and is quarried for building purposes.

As yet no traces of coal have been found, with the exception of a little anthracite; but looking to the position of the carboniferous deposits of northern India, lying as they do on the gneiss formation, it is not impossible that similar deposits may be here met with in like positions.

Specimens of tin, platina, copper, and black oxide of manganese from the southern province have been placed in the museum of the Ceylon Asiatic Society. Quicksilver mines existed at one time in the vicinity of Colombo, and the Dutch are said to have exported the article to Europe. Plumbago is quarried to a great extent, and has for a series of years formed a considerable item in the exports of the island. In 1850 the shipments of this article amounted to 23,823 cwts., in 1860 to 75,000 cwts., and in 1874 to 150,000 cwts. Iron exists in vast quantities in the western, southern, and central provinces, of excellent quality, in many places cropping out at the surface in a state of great purity. The Sinhalese have been accustomed to work the ore into tools and implements from the most remote times; and although the means they employ are rude, imperfect, and wasteful in the extreme, they nevertheless manufacture articles which are esteemed by them far above those imported from Europe, and the rudely worked Sinhalese iron is equal in temper to the finest Swedish metal.

Nitre and nitrate of lime are to be met with in many caves of the low country, whilst alum and sulphate of magnesia are known to exist, though in limited quantities. Natural deposits of common salt are found in many parts of the maritime provinces. It is also produced by artificial means in large quantities under the supervision of Government, in whose hands its manufacture and sale form a monopoly which yields an annual revenue of considerable amount. In 1873 the sale of this article yielded £80,000.

In the Sabaragamuwa district precious stones are met with in great abundance; also, though less commonly, in the Badulla, Nuwara Eliya, and Matara districts. The most valuable are the ruby, the sapphire, the amethyst, the cat's-eye, and the carbuncle. Emeralds are rarely met with in any purity; but the moon-stone, cinnamon stones, and garnets are found in great abundance and variety.

Soil.—The natural soils of Ceylon are composed of quartzose gravel, felspathic clay, and sand often of a pure white, blended with or overlaid by brown and red loams, resulting from the decay of vegetable matter, or the disintegration of the gneiss and hornblende formations. The whole of the great northern extremity of the island consists of a sandy and calcareous admixture, made to yield productive crops of grain, tobacco, cotton, and vegetables by the careful industry of the Tamil population, who spare no pains in irrigating and manuring their lands. Between the northern districts and the elevated mountain ranges which overlook the Bintenne and Uva countries are extensive plains of alluvial soil washed down from the table-lands above, where once a teeming population produced large quantities of grain. The remains of ancient works of irrigation bear testimony to the bygone agriculture of these extensive regions now covered by swamps or dense jungle.

The general character of the soil in the maritime provinces to the east, south, and west is sandy. Large tracts

of quartzose sand spread along the whole line of sea-coast, some of which, of a pure white, and very deficient in vegetable matter, is admirably adapted to the growth of the cinnamon plant. In the light sandy districts, where the soil is perfectly free, and contains a portion of vegetable and mineral loam, the cocoa-nut palm flourishes in great luxuriance. This is the case along the entire coast line from Kalpitiya to Point de Galle, and further eastward and northward to Matara, stretching to a distance inland varying from 100 yards to 3 miles. From this light sandy belt as far as the mountain-zone of the Kandyan country the land is mainly composed of low hilly undulations of sandstone and ferruginous clay, incapable of almost any cultivation, but intersected in every direction with extensive valleys and wide plains of a more generous soil, not highly fertile, but still capable, with a little industry, of yielding ample crops of rice.

The soil of the central province, although frequently containing great quantities of quartzose sand and ferruginous clay, is in many of the more elevated districts of a fine loamy character. Sand sufficiently vegetable and light for rice culture may be seen at all elevations in the hill districts; but the fine chocolate and brown loams overlying gneiss or limestone formations, so admirably adapted for coffee cultivation, are only to be found on the steep sides or along the base of mountain ranges at an elevation varying from 2000 to 4000 feet. Such land well-timbered contains in its elements the decomposed particles of the rocks above, blended with the decayed vegetable matter of forests that have for centuries scattered beneath them the germs of fertility. The quantity of really rich coffee land in these districts is but small as compared with the extent of country,—vast tracts of open valleys consisting of an indifferent yellow, tenacious soil interspersed with many low ranges of quartz rock.

Botany.—The characteristics of the low-growing plants of Ceylon approach nearly to those of the coasts of southern India. The *Rhizophoræ* are numerous along the low muddy shores of salt lakes and stagnant pools; and the acacias are equally abundant. The list comprises *Aciceras fragrans*, *Epithimia malayana*, *Thespesia populnea*, *Feronia elephantum*, *Salvadora persica* (the true mustard tree of Scripture), *Eugenia bracteata*, *Elæodendron Roxburghii*, *Cassia Fistula*, *Cassia Roxburghii*, &c. The herbaceous plants of the low country belong mostly to the natural orders *Compositæ*, *Leguminosæ*, *Rubiaceæ*, *Scrophulariaceæ*, and *Euphorbiaceæ*.

Leaving the plains of the maritime country and ascending a height of 4000 feet in the central districts, we find both herbage and trees assume an altered character. The foliage of the latter is larger and deeper coloured, and they attain a height unknown in the hot low country. The herbaceous vegetation is there made up of ferns, *Cyrtandrea*, *Compositæ*, *Scitamineæ*, and *Urticaceæ*. The dense masses of lofty forest at that altitude are interspersed with large open tracts of coarse wiry grass, called by the natives *patanas*, and of value to them as affording pasture for their cattle.

Between the altitudes of 4000 and 8000 feet, many plants are to be met with partaking of European forms, yet blended with tropical characteristics. The guelder rose, St John's wort, the *Nepenthes distillatoria* or pitcher plant, violets, geraniums, buttercups, sun-dews, ladies' mantles, and campanulas thrive by the side of *Magnoliaceæ*, *Ranunculaceæ*, *Elæocarpeæ*, &c. The most beautiful flowering shrub of this truly alpine region is the rhododendron, which in many instances grows to the height of 70 feet. It is met with in great abundance in the moist plains of the elevated land above Nuwara Eliya, flowering abundantly in June and July. There are two distinct

varieties, one similar to the Nilgiri plant, having its leaves broad and cordate, and of a rusty colour on the under side; the other, peculiar to Ceylon, is found only in forests at the loftiest elevations; it has narrow rounded leaves, silvery on the under side, and grows to enormous heights, frequently measuring three feet round the stem. At these altitudes English flowers, herbs, and vegetables have been cultivated with perfect success, as also wheat, oats, and barley. English fruit-trees grow, but rarely bear. Grapes are grown successfully in the north of the island. The vines were introduced by the Dutch, who overcame the difficulty of perpetual summer by exposing the roots, and thus giving the plants an artificial winter.

Timber.—The timber trees indigenous to Ceylon are met with at every altitude from the sea-beach to the loftiest mountain peak. They vary much in their hardiness and durability, from the common cashew-nut tree, which when felled decays in a month, to the ebony and satinwood, which for many years resist the attacks of insects and climate. The known woods amount to 416 varieties, of which 33 are valuable for furniture, and house and shipbuilding, and are capable of standing long exposure to weather. The most beautiful woods adapted to furniture work are the calamander, ebony, flowered-satinwood, tamarind, nedun, dell, kadomberiya, kitul, cocoa-nut, &c.; the sack-yielding tree (*Antiaris saccidora*), for a long time confounded with the far-famed upas tree of Java (*Antiaris toxicaria*), grows in the Kurunegala district of the island.

Palms.—The *Cocos nucifera*, or cocoa-nut palm, is a native of the island, and may justly be considered the most valuable of its trees. It grows in vast abundance along the entire sea-coast of the west and south sides of the island, and furnishes almost all that a Sinhalese villager requires. Its fruit, when green, supplies food and drink; when ripe, it yields oil. The juice of the unopened flower gives him toddy and arrack. The fibrous casing of the fruit when woven makes him ropes, nets, matting. The nut-shells form drinking-vessels, spoons, &c. The plaited leaves serve as plates and dishes, and as thatch for his cottage. The dried leaves are used as torches, the large leaf-stalks as garden fences. The trunk of the tree sawn up is employed for every possible purpose, from knife-handles to door-posts; hollowed out it forms alike a canoe or coffin. There are four kinds of this palm,—the common, the king, the dwarf, and the Maldiva.

The Palmyra and Areca palms grow luxuriantly and abundantly, the former in the northern, the latter in the western and central districts. The one is valuable chiefly for its timber, of which large quantities are exported to the Indian coasts; the other supplies the betel-nut in common use amongst natives of the eastern tropics as a masticatory. The export trade in the latter to India and eastern ports is very considerable, amounting to £70,000 a year in value.

Cinnamon.—Next in importance to the cocoa-nut palm amongst the indigenous products of Ceylon is the cinnamon plant, yielding the well-known spice of that name.

Animals.—Foremost among the animals of Ceylon is the elephant, which, though far inferior to those of Africa and the Indian continent, is nevertheless of considerable value when tamed, on account of its strength, sagacity, and docility. They are to be met with in greater or less numbers throughout most unfrequented parts of the interior. Occasionally they make inroads in herds upon the cultivated grounds and plantations, committing great damage. In order to protect these lands, and at the same time keep up the Government stud of draught elephants, “kraals” or traps on a large scale are erected in the forests, into which the wild herds are driven; and once secured, they are soon tamed and fit for service. The oxen are of

small size, but hardy, and capable of drawing heavy loads. Buffaloes exist in great numbers throughout the interior, where they are employed in a half-tame state for ploughing rice-fields and treading out the corn. They feed upon any coarse grass, and can therefore be maintained on the village pasture lands where oxen would not find support. Of deer, Ceylon possesses the spotted kind (*Axis maculata*), the muntjac (*Styllocerus muntjac*), a red deer (the Sambur of India), popularly called the Ceylon elk (*Musa Aristotelis*), and the small musk (*Moschus meminna*). There are five species of monkeys, one the small rilawa (*Macacus pileatus*), and four known in Ceylon by the name of “wandaru” (*Presbytes ursinus*, *P. Thersites*, *P. cephalopterus*, *P. Priamus*), and the small quadrumanous animal, the loris (*Loris gracilis*), known as the “Ceylon sloth.” Of the Cheiroptera sixteen species have been identified; amongst them is the rousette or flying fox (*Pteropus Edwardsii*). Of the Carnivora the only one dangerous to man is the small black bear (*Prochilus labiatus*). The tiger is not known in Ceylon, but the true panther (*Felis pardus*) is common, as is the jackal (*Canis aureus*) and the mongoos or ichneumon (*Herpestes vitticollis*). Rats are numerous, as are the squirrel and the porcupine, and the pig-rat or bandicoot (*Mus bandicota*), while the scaly ant-eater (*Manis pentadactyla*), locally known by the Malay name of pengolin, is occasionally found. The dugong (*Halicornia dugong*) is frequently seen on various points of the coast.

Birds.—Upwards of 320 species of birds have been found in Ceylon, and many of them have splendid plumage, but in this respect they are surpassed by the birds of South America and Northern India. The eagles are small and rare, but hawks and owls are numerous; among the latter is a remarkable brown species, the cry of which has earned for it the name of the “devil-bird.” The esculent swift, which furnishes in its edible nest the celebrated Chinese dainty, builds in caves in Ceylon. Crows of various species are numerous, and in the wilder parts pea-fowl are abundant. There are also to be mentioned king-fishers, sun-birds, several beautiful fly-catchers and snatchers, the golden oriole, parroquets, and numerous pigeons, of which there are at least a dozen species. The Ceylon jungle-fowl (*Gallus Lafayetti*) is distinct from the Indian species. Ceylon is singularly rich in wading and water birds.—ibises, storks, egrets, spoonbills, and herons being frequently seen on the wet sands, while flamingoes line the beach in long files, and on the deeper waters inland are found teal and a countless variety of ducks and smaller fowl. Of the birds familiar to European sportsmen there are partridge, quail, and snipe in abundance, and the woodcock has been seen.

Reptiles.—The poisonous snakes of Ceylon are not numerous. Four species have been enumerated,—the ticpolonga (*Daboia elegans*), the cobra di capello (*Naja tripudians*), the caravilla (*Trigonocephalus hypnale*), and the *Trigonocephalus nigromarginatus*, which is so rare that it has no popular name. The largest snake in Ceylon is the “boa,” or “anaconda” of Eastern story (*Python reticulatus*); it is from 20 to 30 feet in length, and preys on hog-deer and other smaller animals. Crocodiles infest the rivers and estuaries, and the large fresh-water reservoirs which supply the rice-fields; there are two species (*C. biporcatus* and *C. palustris*). Of lizards the most note-worthy are the iguana, several bloodsuckers, the chameleon, and the familiar geckoes, which are furnished with pads to each toe, by which they are enabled to ascend perpendicular walls and adhere to glass and ceilings.

Insects.—Insects exist in great numbers. The leaf and stick insects are of great variety and beauty. Ceylon has four species of the ant-lion, renowned for the predaceous ingenuity of its larvæ; and the white ants or termites, the

ravages of which are most destructive, are at once ubiquitous and innumerable in every place where the climate is not too chilly, or the soil too sandy for them to construct their domed dwellings. They make their way through walls and floors, and in a few hours destroy every vegetable substance within their reach. Of all the insect pests that beset an unseasoned European the most annoying are the mosquitoes. Ticks are also an intolerable nuisance; they are exceedingly minute, and burrow under the skin. In the lower ranges of the hill country land leeches are found in tormenting profusion.

Fishes.—Of the fish in ordinary use for the table the finest is the seer, a species of scomber (*Cybium guttatum*). Mackerel, dories, carp, whitiugs, mullet (red and striped), soles, and sardines are abundant. Sharks appear on all parts of the coast, and the huge saw fish (*Pristis antiquorum*) infests the eastern coast of the island, where it attains a length of from 12 to 15 feet. There are also several fishes remarkable for the brilliancy of their colouring; e.g., the Red sea perch (*Holocentrum rubrum*), of the deepest scarlet, and the great fire fish (*Scorpena miles*), of a brilliant red. Some are purple, others yellow, and numbers with scales of a lustrous green are called "parrots" by the natives; of these one (*Sparus Hardwickii*) is called the "flower parrot," from its exquisite colouring—irregular bands of blue, crimson, and purple, green, yellow and grey, crossed by perpendicular stripes of black.

Pearl Fishery.—Pearl oysters are found in the Tambalagam bay, near Trincomalee, but the great banks on which these oysters are usually found lie near Arippe, off the northern part of the west coast of Ceylon, at a distance of from 16 to 20 miles from the shore. They extend for many miles north and south, varying considerably in their size and productiveness. A naturalist was recently employed by the Government for five years to study the habits of the pearl oysters, but no information of any value has been obtained. It is, however, generally believed that the oyster arrives at maturity in its seventh year, that the pearl is then of full size and perfect lustre, and that if the oyster be not then secured it will shortly die, and the pearl be lost. It is certain that from some unexplained cause the oysters disappear from their known beds for years together. The Dutch had no fishery from 1732 to 1746, and it failed them again for 27 years from 1768 to 1796. The fishery was again interrupted between 1820 and 1828, also from 1833 to 1854, and from 1864 to 1873. In 1797 and 1798 the Government sold the privilege of fishing the oyster-beds for £123,982 and £142,780 respectively. Since that time the fishery has been conducted by the Government itself, which sells the oysters in heaps of 1000 as they are landed from the boats. Under this system, however, receipts have not exceeded £87,000 in any year, and have fallen as low as £7200, which was the net revenue from the fishery of 1874. The fishery immediately preceeding (that of 1863) yielded a net revenue of £46,000. The small oyster found at Tambalagam is the *Placuna placenta*; the pearl-oyster of the Arippe banks is the *Meleagrina margaritifera*.

History.—The island of Ceylon was known to the Greeks and Romans under the name of *Taprobane*, and in later times Sereudib, Sirinduili, and Zeylan have been employed to designate it by writers of the Western and Eastern Worlds. Serendib is a corruption of the Sanskrit *Sinhaladvīpa*. Like most Oriental countries, Ceylon possesses a great mass of antiquarian records, in which the real is so intimately and largely blended with the ideal that the student finds it difficult to determine the respective limits of history and fable. The labours of Turnour have, however, helped to dissipate much of what was before confused and contradictory, and in his admirable translation of the "Mahawanso" we may trace the true current of Sinhalese history.

Of the first colonization of Ceylon but little is known. In the great Hindu epic, the Ramayana, we have the fable of the conquest of a part of Ceylon by the hero Rama and his followers, who, as the poem tells, besieged and took the capital of its king Ravana. No permanent occupation of the country took place at this time, nor until the advent, in 543 B.C., of Vijaya an Indian prince, who, arriving from the mainland with a small band of followers, succeeded in establishing himself as sole ruler of the country. To this king is attributed the introduction of *caste* into Ceylon, an institution which, although far less rigorously observed than on the continent, is still maintained.

Under him and his successors Ceylon attained a degree of civilization scarcely to be looked for in that remote age of Oriental despotism. The purity of the religious and moral code, the strict administration of justice, and the well-defined and carefully protected rights of the king and his many classes of subjects excite our admiration not less than our astonishment. It is impossible, however, to follow the subsequent current of Sinhalese history through its many intricate windings. It must suffice to say that the descendants of Vijaya the conqueror continued to hold the reins of government with varied ability and unequal success. Some of them were distinguished for their learning, their military prowess, their benevolence, and the length of their reigns. Others lived amidst civil dissensions and foreign invasions, which not unfrequently cost them their lives. The incursions of the Malabars upon their territories were not less frequent and fatal than those of the Danes in Britain. During a period of four or five centuries, these marauders continued to pour their bands of armed men into the island; and so far had the country fallen off from its ancient prosperity and strength that when, in the year 1505, the Portuguese adventurer Almeida landed at Colombo, he found the island divided into seven separate kingdoms.

The first settlement of the Portuguese was effected in 1517, when Albergaria succeeded in obtaining permission from the king of Kotta, whose territories closely adjoined Colombo, to erect a small factory on the latter spot for purposes of trade. Once established, the new-comers lost no opportunity of strengthening their position and extending their intercourse with the natives. Stone walls quickly took the place of palisades; the factory became a fort; whilst bristling cannon commanded alike the approaches by land and the entrance by sea. Alarmed at these unequivocal signs of military possession, the Sinhalese kings attempted to expel their new friends from the island, in which they were joined by the Moorish and other traders opposed to the progress of the Portuguese. But their efforts were too late, and proved ineffectual; and after a series of unequal and sanguinary conflicts, the Europeans found themselves in secure possession of the west coast of Ceylon.

The fanatical zeal and remorseless cruelty of the Portuguese were a constant source of dissension with the natives; and when, in the year 1602, the Dutch, under Admiral Spilberg, landed on the east coast and sought the alliance of the king of Kandy in the interior of the island, every encouragement was held out to them with the view of inducing them to aid in expelling the Portuguese. Nothing seems to have come of this until 1638–9, when a Dutch expedition attacked and razed the Portuguese forts on the east coast. In the following year they landed at Negombo, without, however, establishing themselves in any strong post. In 1644 Negombo was captured and fortified by the Dutch, while in 1656 they took Colombo, and in 1658 they drove the Portuguese from Jaffna, their last stronghold in Ceylon.

Pursuing a wiser policy than their predecessors, the

Dutch lost no opportunity of improving that portion of the country which owned their supremacy, and of opening a trade with the interior. More tolerant and less ambitious of military renown than the Portuguese, they so far succeeded in their object as to render their commerce between this island and Holland a source of great profit. Many new branches of industry were developed. Public works were undertaken on a large scale, and education, if not universally placed within the reach of the inhabitants of the maritime provinces, was at least well cared for on a broad plan of Government supervision.

That which they had so much improved by policy they were, however, unable to defend by force when the British turned their arms against them. A century and a half had wrought great changes in the physical and mental status of the Dutch colonists. The territory which in 1658 they had slowly gained by undaunted and obstinate bravery, they as rapidly lost in 1796 by imbecility and cowardice.

The first intercourse of the English with Ceylon took place as far back as 1763, when an embassy was despatched from Madras to the king of Kandy, without, however, leading to any result. On the rupture between Great Britain and Holland in 1795, a force was sent against the Dutch possessions in Ceylon, where the opposition offered was so slight that by the following year the whole of their forts were in the hands of the English commander.

At first the island was placed under the care of the East India Company, but in 1802 the whole seaboard of Ceylon became, by the treaty of Amiens, a possession of the British Crown. The central tract of hilly country, hedged in by impenetrable forests and precipitous mountain ranges, remained in possession of Wikrama Sinha, the last of the Malabar dynasty of kings, who showed no signs of encouraging communication with his European neighbours.

Minor differences led in 1803 to an invasion of the Kandyan territory; but sickness, desertion, and fatigue proved more formidable adversaries to the British forces than the troops of the Sinhalese monarch, and peace was eventually concluded upon terms by no means favourable to the English. The cruelty and oppression of the king now became so intolerable to his subjects that disaffection spread rapidly amongst them. Executions of the most horrible kinds were perpetrated. The utmost stretch of despotism failed to repress the popular indignation; and in 1815 the British, at the urgent request of many of the Adigars and other native chiefs, proceeded against the tyrant, who was captured near Kandy, and subsequently ended his days in exile. With him ended a long line of sovereigns, whose pedigree may be traced through upwards of two thousand years.

By a convention entered into with the Kandyan chiefs on the 2d of March 1815, the entire sovereignty of the island passed into the hands of the British, who in return guaranteed to the inhabitants civil and religious liberty. The religion of Buddha was declared inviolable, and its rights, ministers, and places of worship were to be maintained and protected; the laws of the country were to be preserved and administered according to established forms; and the royal dues and revenues were to be levied as before for the support of Government.

With the exception of a serious outbreak in some parts of the interior in 1817, which lasted for upwards of a year, and of two minor attempts at rebellion easily put down, in 1843 and 1848, the political atmosphere of Ceylon has remained undisturbed since the deportation of the last king of Kandy.

Population.—The total population of Ceylon, as ascer-

tained by the census of March 1871, is given as 2,406,262. Its distribution according to Provinces is as follows:—

Province.	Population.	Area.	Population to square mile.
Western	775,285	3,345	232
North-Western	269,084	2,383	113
Southern	399,755	1,937	206
Eastern	113,290	3,516	32
Northern	281,788	3,139	89
Central	495,340	5,770	85
North-Central	70,720	4,384	16
Total.....	2,406,262	24,474	98

The principal towns with these populations are—Colombo 95,843, Galle 47,059, and Jaffna 34,864.

The distribution according to race is as follows:

Sinhalese.....	1,670,207
Tamils.....	540,685
Arab descendants	163,516
Malays.....	7,952
Other Asiatics, Kafirs, &c.	3,835
European descendants and half-castes...	14,181
Europeans	5,886

Total..... 2,406,262

Government.—Ceylon is a Crown colony, that is, a possession of the British Crown acquired by conquest or cession, the affairs of which are administered by a governor, who receives his appointment from the Crown, generally for a term of six years. He is assisted by an executive and a legislative council. The executive council acts as the cabinet of the governor, and consists of the Queen's advocate, the three principal officers of the colony (namely, the colonial secretary, the treasurer, and the auditor-general), and the general in command of the forces. The legislative council, in addition to the members of the executive, includes the two principal civil officers of the western and central provinces, the surveyor-general, the collector of customs, and six unofficial members nominated by the governor, who generally selects three to represent the planting and mercantile community, and three to represent the Sinhalese, Tamil, and Eurasian inhabitants; the governor presides and has a casting vote, if the numbers are equal, in addition to his original vote. There are thus nine official members and six unofficial. The powers of the governor constitute a "paternal despotism," controlled only by the distant authority of the Crown, as exercised through the secretary of state for the colonies. The functions of his councils are consultative; the adoption or rejection of their recommendations rests exclusively with himself. The executive council is the body by whose advice all Government measures are originally framed preparatory to their submission to the legislative council, by whom they are finally discussed with all the forms of parliamentary debate; still the paramount authority of the governor can overrule their deliberations, and their labours may be nullified by his withholding his assent, which is necessary to give an enactment the force of law pending its allowance or disallowance by the Crown. All legislative enactments must be published in the local gazette for three weeks before they can be finally adopted by the legislature. A certain portion of the colonial expenditure is covered by permanent ordinances, which provide for the fixed establishments of the colony, the contribution towards the military defence of the colony, and the payment of interest and sinking fund on account of loans. All other expenditure has to be covered by an annual vote of the legislative council. The administration is carried on by a civil service, organized on the model of the great institution by which our Indian empire has been formed. It is recruited by members selected by competition from a limited number of candidates nominated by the secretary of state and the governor of Ceylon. The selected candidates are carefully trained in the colonial office at Whitehall and in the public offices in Ceylon, and are also required to pass an examination in the native languages before being employed in any responsible office. For this highly-trained body the more important civil appointments in Ceylon, including many of the judicial appointments, are reserved. The old routine system of rising by seniority was abolished by the order of the earl of Derby in 1845, and merit instead of seniority is professedly now the basis of promotion. The island is divided into seven provinces, each having its chief and assistant agents, who carry on the affairs of the province under the direct authority of the Government. The agents of Government are the sole means of communication between the Government and the native inhabitants of the island;

it is their duty to ascertain the real feelings of the people in reference to any Government measure the expediency of which may be doubtful, and to keep them thoroughly acquainted with any change in the law, and also to bring before the Government the wants of the people, and to obtain early information of any disaffection or fear of a rising of the people. They have consequently very delicate and important duties to perform in relation to the native chiefs and nobles. They have also to collect, through their subordinates, all the revenue not derived from customs duties, to see that the public buildings and highways are kept in proper order, and generally to see to the welfare of the province. The provinces are divided into districts under an assistant agent, and the districts are parcelled out into smaller divisions under native chiefs and headmen of various ranks,—called in the Kandyan country *Ratemahatmayas*, *Koralas*, and *Arachchies*; in the maritime Sinhalese provinces *Mudaliyas*, *Muhandirams*, and *Vidanas*; in the Tamil provinces *Vanniyas*, *Udaiyars*, and *Vidanas*. The Kandyan provinces are the central, north-central, and parts of the western and north-western; the maritime or low-country Sinhalese provinces are the southern and parts of the western and north-western; the Tamil provinces are the northern and eastern.

Justice.—The administration of justice is conducted by a Supreme Court, consisting of a chief justice and two puisne judges; by district judges, police magistrates, justices of the peace, and commissioners of Courts of Request. There are a Queen's advocate and a deputy Queen's advocate for the island. These officers correspond to the attorney-general and solicitor-general in England. They are the law officers of the Government, and are bound to give their advice on any case submitted for their opinion, and to appear for the Crown in all civil suits. The Queen's advocate also has to discharge the duties of public prosecutor, to supervise the proceedings of the justices of the peace, and to conduct the prosecution in all cases before the Supreme Court and in all serious cases before the District Courts. The Queen's advocate is assisted by provincial deputies, who are the legal advisers of the agents of Government in charge of the provinces.

The Supreme Court has original criminal jurisdiction in all cases. It usually tries only cases ordinarily punished with more than one year's imprisonment; in all criminal cases it has the assistance of a jury. It goes on circuit twice a year for criminal cases. It has appellate jurisdiction, civil and criminal, over all the subordinate courts in the island, and the power to issue writs of mandamus and habeas corpus. The District Courts have criminal jurisdiction in cases ordinarily punishable by twelve months' imprisonment with or without hard labour, by a fine of £100 or, more strictly, 1000 rupees, or by 50 lashes, or by imprisonment and fine, or by imprisonment and lashes within the specified limits. They have original civil jurisdiction in all cases, whether affecting land or not, in lunacy, in testamentary and matrimonial cases, and in administering the estates of minors and intestates. They have long exercised the combined powers of the Court of Chancery and the Courts of Law which have been only recently conferred by the Judicature Acts on the Supreme Court of Judicature in England. The District Courts have no jury, but they have the power, which, however, is rarely exercised, of summoning assessors to their assistance. The police courts have jurisdiction in cases ordinarily punishable by imprisonment with or without hard labour for three months, by a fine of £5 or 50 rupees, or by twenty lashes, or by imprisonment and fine, or by imprisonment and lashes within the specified limits. The Courts of Requests have jurisdiction in civil cases where the matter in dispute is not of greater value than £10. The pleadings in all the courts are in English, but the proceedings are conducted in the language of the district unless both parties are English. The evidence is interpreted and recorded in English.

Village Tribunals.—In ancient times all petty disputes were settled by the village elders, who formed the village council or *gamsabawa*. When the island fell under European control these native customs were rudely swept away, and courts were established which were to administer justice equally to all. In course of time it was found that these courts were in reality highly oppressive to the people, who are of a litigious disposition, by bringing parties and witnesses away from their homes for the settlement of every petty case and involving them in costs for stamps and legal assistance, the costs often being tenfold the value of the matter in dispute. It was also found that the ancient customs by which each shareholder in arable land was compelled to take his proper share in the common work, such as fencing, repairing the dams of the reservoir for irrigation, and the like, had gradually fallen into disuse under British rule. It was consequently determined by Sir Hercules Robinson, then governor of Ceylon, to revive the ancient system, and by the "Village Communities Ordinance, 1871," power was given to every village or group of villages to frame rules, having the force of law, for the management of village affairs, and to form village tribunals on the ancient model for the settlement of all petty cases, such as petty assaults and the like, punishable by a small fine, and all civil cases of £2 and under. These tribunals are presided over by a native of rank and experience. The experiment has proved a suc-

cess beyond the expectation of its original advocates. The relief to the people in getting their small disputes settled on the spot by their own elders is very great, and the revival of the ancient village customs is leading to the general restoration of the village tanks and other irrigation works, which were rapidly falling into decay from the failure of the Government to enforce the ancient rules for their preservation.

Laws.—In the maritime provinces ceded to Great Britain by the peace of Amiens the Roman-Dutch law prevails; in the Kandyan provinces the Kandyan law is administered under the convention of 1815. The Mahometans have their own laws of marriage and succession. The English law of evidence, trial by jury in the more serious criminal cases, and the English mercantile law have been introduced by local enactments. The Roman-Dutch law applies where no other system of law specially applies. Cases frequently occur in which it is a matter of the utmost difficulty to determine by which system of law they are to be decided, and it is a matter for surprise that no attempt has been made to codify the Ceylon laws, or at least to adapt to the not very different circumstances of Ceylon the admirable civil and criminal codes, and the regulations of procedure, which have been given to India by the able men who have followed Lord Macaulay in the great task of regulating the administration of justice in India.

Language.—The language of nearly 70 per cent. of the population is Sinhalese; of the remaining 30 per cent., with the exception of about 6000 Europeans and about 14,000 of European descent, the language is Tamil. Sinhalese is an Aryan language, nearly allied to Pali, which is the sacred language of Buddhism. Tamil is a Dravidian language spoken by those of Arab descent and by the Tamils, who are natives of the northern and eastern provinces, as well as by the Tamil immigrants from Southern India. A corrupt form of Portuguese is spoken by some natives of European descent. The Vaddas, a small forest tribe, speak a distinct language, and the Rodiyas, an outcast tribe, possess a large vocabulary of their own. Pali is one of the Prakrits of ancient India, "which was spoken in the sixth century before Christ, and has been a dead language for upwards of two thousand years." It was the dialect of Magadha, or Southern Behar, and was the language in which Gautama Buddha preached. "Originally a mere provincial dialect, it was raised by the genius of the great reformer to the dignity of a classic language. It stands to Sanskrit in the relation of a younger sister; Pali and Sanskrit, though intimately connected, being independent corruptions of the lost Aryan speech which is their common parent."

Literature.—The Sinhalese possess several original poems of some merit, and an extensive and most interesting series of native chronicles, but their most valuable literature is written in Pali, though the greater portion of it has been translated into Sinhalese, and is best known to the people through these Sinhalese translations. The Pali literature is of great extent; it comprises—(1.) The Buddhist Scriptures, called the Tripitaka, estimated in extent at eleven times that of our own Bible, and dating from 309 B.C.; (2.) The commentaries of Buddhaghosha, which date from the 5th century A.D.; and (3.) Historical, grammatical, and other works, of various dates from the 2d or 3d century to the present day, of which the most important are the two histories *Dipavamsa* and *Mahavamsa*, the discovery of which made the name of George Turnour illustrious, for in them we find the only authentic sources for the history of India previous to the Christian era. The treasures of the Pali literature are gradually being opened up to European scholars; foremost amongst those who have sought to raise Pali scholarship to a science are a Frenchman and a Dane. Burnouf has left behind him the important works—*Introduction à l'Histoire du Bouddhisme* and *Le Lotus de la Bonne Loi*; and Fausbøll is now editing the text of the entire *Jataka*, or *History of the Births of Buddha*. This work is being translated by an Englishman, Professor Childers, whose valuable dictionary is an immense boon to the Pali student.

Religions.—The census of 1871 gives the following figures :—

Buddhists.....1,520,575	Mahometans.....171,542
Hindus.....465,914	Christians.....210,042

Of the Christians, about 186,000 are Roman Catholics, and 54,000 are Protestants of various denominations; and it is estimated that about 150,000 of them are Sinhalese, 72,000 Tamils, and 18,000 Europeans and Eurasians. The Mahometans are the descendants of Arabs (locally termed Moormen) and the Malays. The Tamils, both the inhabitants of the island and the immigrants from India, are Hindus, with the exception of the 72,000 Christians. The Sinhalese, numbering 70 per cent. of the whole population, are, with the exception of 150,000 Christians, Buddhists. Ceylon may properly be called a Buddhist country, and it is here that Buddhism is found almost in its pristine purity. Ceylon was converted to Buddhism about 300 years B.C. by the great Augustine of Buddhism, Mahinda, son of the Indian king Dhaumasaoka; and the extensive ruins throughout Ceylon, especially in the ancient cities of Anuradhapura and Polonnaruwa, bear witness to the sacrifices which kings and people joined in making to create lasting monuments of their faith. Under European rule royal support is no longer given to it, but its pure and simple doctrines live in the hearts of the people, and are the noblest monument to the memory of its founder Gautama Buddha. The taking of the meanest life is strictly forbidden, and falsehood, intemperance, dishonesty, anger, pride, and covetousness are denounced as incompatible with Buddhism, which enjoins the practice of chastity, gratitude, contentment, moderation, forgiveness of injuries, patience, and cheerfulness. The Buddhist priests are sworn to celibacy, and are regularly ordained. They are required to meet at convenient places every fourteen days for mutual confession. The Buddhist Temples in the Kandyan country possess valuable lands, the greater portion of which is held by hereditary tenants on the tenure of service. These lands were given out with much care to provide for all that was necessary to maintain the temple and its connected monastery. Some tenants had to do the blacksmiths' work, others the carpenters', while another set of tenants had to cultivate the land reserved for supplying the monastery; others again had to attend at the festivals, and prepare decorations, and carry lamps and banners. In course of time difficulties arose; the English courts were averse to a system under which the rent of lands was paid by hereditary service, and a commission was issued by the governor, Sir Hercules Robinson, to deal with the whole question, to define the services and to enable the tenants to commute these for a money payment. The result of the inquiry was to show that the services, except in a few instances, were not onerous, and that almost without an exception the tenants were willing to continue the system. The Government maintains an ecclesiastical establishment consisting, for the Church of England, of a bishop, whose see is Colombo, an archdeacon, four principal chaplains, and several junior chaplains; and, for the Church of Scotland, of four principal chaplains. The total cost of this establishment is about £14,000 a year. Various missionary bodies have established themselves in Ceylon.

Caste.—Caste exists among the Sinhalese as a conventional and social, not as a sacred institution. All castes, however low, are eligible to the priesthood, which commands the homage of the highest. Buddha teaches that—

"A man does not become low caste by birth,
Nor by birth does one become high caste;
High caste is the result of high actions—
And by actions does a man degrade himself to caste
that is low."

Nevertheless, caste was tolerated under the Sinhalese kings as a social institution, and in the account given in the *Mahavamsa* of the planting of the great Bo tree, it is said that "the sovereign, the lord of chariots, directed that it should be lifted by the four high caste tribes and by eight persons of each of the other castes." The highest caste among the Sinhalese is the goi-vansa, or tillers of the soil; there are, besides, fishers, smiths, washers, baggage-carriers, weavers, potters, scavengers, and many others. Every trade is a caste. The castes do not intermarry, and neither wealth nor European influence has had any effect in breaking down caste distinctions. At present the wealthiest native of Ceylon is a fisher by caste, but his wealth cannot gain him admittance to the houses of the native aristocracy, who are all of necessity of the highest caste. The Tamils have the same caste distinctions as their fellows on the mainland. The Mahometans have no caste distinctions.

Education.—The Ceylon Government maintains a large number of public schools, chiefly of the village class; and there are throughout the island several schools under the management of the Roman Catholics and other missionary bodies, which receive large grants from Government in the form of payments for results in subjects of secular instruction. The education department is under a Director of Public Instruction. The following is an abstract of the school returns for 1874 :—

	Number of Scholars.		
	Male.	Female.	Total.
253 Public Schools,.....	10,376	1,343	11,719
4 Regimental Schools,...	331	27	358
832 Free Schools,.....	33,551	10,825	44,376
329 Private Schools,.....	8,569	1,360	9,929
Total,.....	52,830	13,555	66,385

The annual expenditure by the Government on education is upwards of £30,000; of which from £17,000 to £18,000 is expended on general administration and salaries of masters of public schools, and £13,000 on grants in aid and other contingent charges.

Crime.—The criminal statistics for the year 1874 give the following figures, having reference to a population of upwards of 2,400,000. The justices of the peace made 10,171 preliminary inquiries, of which 2750 related to offences against the person, 2452 to cattle stealing, 3706 to offences against property, and 1263 to other offences; 1807 persons were committed for trial in the superior courts, of whom 528 were sent up for offences against the person, 552 for cattle stealing, 452 for offences against property, and 275 for other offences. There were 11,794 summary convictions in the magistrates' courts, of which 2568 were for assaults, &c.; 178 malicious injuries; 1678 other offences against property; 5779 offences against Revenue Acts, Highway Acts, Health Acts, and the like; 437 under Masters and Servants Acts; and 1154 other offences. A comparison of the statistics for 1872, 1873, and 1874 shows a slight increase, under almost every head in 1874, as compared with the two previous years.

Diseases.—Ceylon is reputed to be more healthy than most parts of the adjoining continent of India. It is doubtful, however, how far this is true. It is a point which it is difficult to bring to the test of statistics. Experience proves that with ordinary care Europeans may pass many years in the island as free from disease as in any part of Europe, but a lengthened residence almost invariably induces a reduced vigour in the whole muscular apparatus. The diseases to which Europeans are most subject are dysentery and hepatic attacks. The returns from the

native hospitals for 1874 show that chronic dysentery, diarrhoea, anasarca, and asthenia are the most fatal. In the principal hospital in Ceylon, namely, the Maradana hospital, near Colombo, out of 292 deaths 34 were from chronic dysentery, 99 from diarrhoea, 33 from anasarca, and 18 from asthenia; in the Kandy hospital, out of 304 deaths, 14 were from chronic dysentery, 99 from diarrhoea, 94 from anasarca, and 42 from asthenia; in the Galle hospital, out of 89 deaths, 4 were from chronic dysentery, 14 from diarrhoea, 11 from anasarca, and 1 from debility.

Roads.—The policy of the Sinhalese rulers of the interior was to exclude strangers from the hill country. Prior to the British occupation of the Kandyan territory in 1815, the only means of access from one district to another was by footpaths through the forests. The Portuguese do not appear to have attempted to open up the country below the hills, and the Dutch confined themselves to the improvement of the inland water-communications. The British Government saw from the first the necessity of making roads into the interior for military purposes, and, more recently, for developing the resources of the country. The credit of opening up the country is due mainly to the governor, Sir Edward Barnes, by whose direction the great military road from Colombo to Kandy was made. Gradually all the military stations were connected by broad tracks, which by degrees were bridged and converted into good carriage roads. The governors Sir Henry Ward and Sir Hercules Robinson recognized the importance of giving the coffee planters every assistance in opening up the country, and the result of their policy is that the whole of the hill country is now intersected by a vast number of splendid roads, made at a cost of upwards of £2000 per mile. In 1848 an ordinance was passed to levy from every adult male in the colony (except Buddhist priests and British soldiers) six days' labour on the roads, or an equivalent in money. The labour and money obtained by this wise measure have enabled the local authorities to connect the Government highways by minor roads, which bring every village of importance into communication with the principal towns. The expenditure in 1874 out of the revenues of the colony on roads, streets, bridges, and canals was, in round numbers, £175,000, of which sum £113,500 was expended in the ordinary maintenance of existing roads. The expenditure by the local authorities under the road ordinance amounted in the same year to £65,000, and by the municipalities of Colombo, Kandy, and Galle to £23,000.

Railways.—After repeated vain attempts by successive governors to connect Colombo with the interior by railways, Sir Charles MacCarthy successfully set on foot the present railway of 75 miles in length from Colombo to Kandy, which is probably the most prosperous in the world. It was constructed at a cost of £1,738,483. The gross receipts in 1872 were £226,000, and the working expenses £89,000, or about 38 per cent. of the gross earnings. A branch railway from Peradeniya (four miles from Kandy) to Navalapitiya, 17 miles in length, has just been completed, and a line from Colombo to Moratuwa, 11 miles in length, has been commenced; the latter line will probably be extended to Kalutara, distant 26 miles from Colombo. The line from Colombo to Kandy is remarkable for its beauty, and for the engineering skill shown in its construction. The ruling gradient for the first 50 miles is 1 in 100; the line then rises for 12 miles with a gradient of 1 in 45 throughout and curves of 10 chains radius, to the Peradeniya station, which is 1562 feet above the sea-level. The Navalapitiya railway station is 1913 feet above the sea-level.

Agriculture.—The Sinhalese are more attached to the

pursuit of agriculture than any other occupation, and although their implements are of the rudest kind, and their processes the most simple, they succeed in obtaining successive crops of grain of good quality wherever they can secure sufficient water. The chief culture in every part of the island is that of rice, the staple food of all the native races in Ceylon.

Rice.—In a few places, where the rain-fall is abundant, rice cultivation is allowed to depend on the natural supply of water, but in most parts the cultivation is not attempted unless there is secured beforehand a certain and sufficient supply, by means of canals or reservoirs. In the hill country every valley and open plain capable of tillage is made to yield its crops of grain, and the steep sides of the hills are cut into terraces, on which are seen waving patches of green rice watered by mountain streams, which are conducted by means of channels ingeniously carried round the spurs of the hills and along the face of acclivities, by earthen water-courses and bamboo aqueducts, so as to fertilize the fields below. These works bear witness to the patience, industry, and skill of the Kandyan villagers. In the low country to the north and east and north-west of the hills, irrigation works of a more expensive kind are necessary.

Irrigation.—The native rulers covered the whole face of the country with a network of irrigation reservoirs, by which Ceylon was enabled in ancient times to be the great granary of Southern Asia. Wars, and the want of a strong hand to guide the agriculture of the country, have led to the decay of these ancient works, and large tracts of land, which were formerly highly productive, have become swampy wastes or dense forests. The remains of some of the larger irrigation works are amongst the most interesting of the memorials of Ceylon's former greatness. Some of the artificial lakes were of great size. Mineriya, formed by damming across the valleys between the low hills which surround it, with an embankment 60 feet wide at the top, is at this day twenty miles in circumference. Another with an embankment several miles in length, the Kalawewa, was formed by damming back the waters of the Kalaoaya, but they have forced their way through the embankment, and in the ancient bed of the lake, or tank, are now many small villages. In connection with these large tanks were numerous canals and channels for supplying smaller tanks, or for irrigating large tracts of fields. Throughout the district of Nuwarakalawiya every village has its tank. The embankments have been formed with great skill, and advantage has been taken to the utmost of the slightest fall in the land; but they in common with the larger works had been allowed to fall into decay, and were being brought to destruction by the evil practice of cutting them every year to irrigate the fields. The work of restoring these embankments has at last been undertaken by the Government. Proper sluices will gradually be supplied to all the village tanks, and the embankments will be raised and strengthened by the united labour of the villagers in proportion to their shares in the fields under the *gamsabāwa* system.

Dry Grains.—Several dry grains (so called as distinguished from rice, which is grown in water) are grown in Ceylon. These are chiefly kollu, millet, kurakkan, gingele, and pulse of various kinds.

Tobacco.—Tobacco is extensively cultivated in various parts of the island, and the growth of particular places, such as Dumbara and Uva, is much prized for local consumption. The tobacco of export is grown in the peninsula of Jaffna, where the rajah of Travancore has an agent who purchases for him direct from the growers. The exports of this article in 1850 were 22,176 cwts., valued at £20,698, and in 1873, 36,676 cwts., valued at £99,174.

Cinnamon.—Ceylon has been celebrated since the middle of the 14th century for its cinnamon, and during the period of the Dutch occupation this spice was the principal article of commerce; under their rule and up to 1832 its cultivation was a Government monopoly. With the abolition of the monopoly the quantity exported increased, but the value declined. European consumers contented themselves with the cheaper and coarser cassia, and the Ceylon producers then peeled the coarser and less valuable shoots of cinnamon to compete with the cassia, till the average price in London, which was 5s. 1d. per lb in 1841, was reduced in 1857 to 1s. 6d. per lb. Cassia during this period varied from 1s. 1½d. to 6½d. per lb. The customs returns give the exports for 1850 at 664,857 lb, valued at £64,486, and for 1873 at 1,160,754 lb, valued at only £58,037.

Coffee.—The most important cultivation is that of coffee, a branch of industry which since the year 1841 has assumed a position of great and ever-increasing prominence. Coffee was an article of growth and export from Ceylon so far back as the time of the Portuguese, but like the cinnamon it grew wild without any attempt at cultivation. Patches of it were to be seen around the Kandyan villages in wild luxuriance; and the berry, gathered before it was ripe, and imperfectly cured, seldom possessed much flavour, and was lightly esteemed as an article of European commerce. Coffee cultivation on the West Indian plan was first commenced in 1824 by Sir E. Barnes, then governor of Ceylon, who hoped by his example to introduce coffee-planting by Europeans into the island. Until 1834, however, public attention does not seem to have been occupied with the subject; but in that year the falling off in the supplies from other quarters brought capitalists into the field; and when in 1836 the home duty on East India coffee was reduced to 6d. per lb, a great impulse was given to coffee planting in Ceylon. During that and the following year about 7000 acres of forest land were purchased for this object; and when at the end of a few years it became matter of notoriety that the soil and climate of Ceylon were capable of yielding a coffee equal in value to most kinds, the influx of capital from England for investment in this new branch of Ceylon industry became very great.

The commercial crisis of 1847 gave a check to coffee-planting in the island, and caused the abandonment of several estates. But enforced economy induced more careful cultivation, and the coffee enterprise soon recovered. There are now 1,215 coffee plantations of which 800 are owned by individual proprietors, 250 of whom reside on their own estates, and 400 more are resident in the island. The area is estimated at 250,000 acres, of which 195,000 are in bearing. The exports from these plantations for the coffee season ending 10th Oct. 1874 were 850,000 cwt., giving an average yield from old and new estates together of a little over 4 cwt. per acre. Estates from 5 to 10 years old probably yield about four and half cwt. per acre, and older estates about three and a half cwt. per acre. The price for plantation coffee in the London markets in 1845 was 74s. per cwt.; it has fluctuated considerably, and went down to 50s. in 1851, but it did not rise much above the price of 1845 till 1872, when it steadily rose till it reached 139s. on Feb. 7th, 1873. Land suitable for coffee is purchased from the Government in forest. It was formerly sold in large blocks at an upset price of 5s. an acre; it is now sold in convenient blocks of 200 acres or less at an upset price of £1 an acre; no land, however, which is really well suited for coffee can be obtained at less than £9 or £10 an acre, and in 1873 a lot of 306 acres of forest land sold for £18 per acre. Including the lands sold in small lots to natives, the Government granted from 1833 to 1844

267,373 acres, and between 1844 and 1874 693,886 acres; the average price per acre has risen from 10s. 8d. to £2, 12s. 4d. per acre. The exports of coffee in 1850 were 278,473 cwt., valued at £609,262, and in 1873, 951,591 cwt., valued at £4,220,750.

Tea.—The cultivation of tea has recently been introduced. A small quantity of pure good tea is produced annually, and finds a ready market in the island. It has not yet become an article of export.

Cinchona.—Cinchona was introduced into the hill-districts of Ceylon and India from South America in 1860. It was brought direct from the forests, where it maintained an incessant struggle with other trees for existence. After patient and intelligent experiment its cultivation has been assured, and the object of its introduction secured. There is now provided an abundant supply of the bark at a price which will secure to the population at large the valuable febrifuge yielded by the alkaloids of cinchona.

Sugar.—The cultivation of sugar was commenced in 1836 near Kandy, and subsequently in several other parts of the island, but without any permanent success; the sugar grown in the island forms a very small portion of the annual consumption. The sugar imported in 1873 amounted to 28,956 cwt., valued at £46,953.

Cocoa-nuts.—As an investment for English capital cocoa-nut planting has not proved remunerative. To the native cultivator a small cocoa-nut plantation adjoining his homestead is of the utmost value, as has been already explained under the head "palms." It is estimated that the extent of land, held by Europeans and natives, bearing cocoa-nuts is 250,000 acres.

Manufactures.—The native manufactures are of the most primitive description. Coarse cotton cloth of a strong and serviceable kind is woven in rude looms, but the looms are rapidly disappearing with the introduction of the cheaper but inferior productions of Manchester. The fibre of the cocoa-nut is worked up in large quantities into coir yarn and cordage, which is admirably adapted for use in salt water. The country trading vessels employ no other cordage or rope than this, and indeed the planks of their small vessels are held together solely by coir yarn, without the aid of a single nail. Cocoa-nut oil is expressed from the dried kernel of the cocoa-nut in native mills, which are simply a rough mortar of wood or stone in which a heavy pestle of hard wood is made to revolve by means of a pair of oxen at the end of a long pole, secured by a bamboo to the upper end of the pestle, the whole machine forming a simple kind of lever, by the action of which the oil is extracted. Steam-power is now used by European merchants in manufacturing this oil and in preparing and pressing coir fibre, and oil and coir have become important articles of export. In 1850 the exports of coir rope, yarn, &c., were 39,886 cwt., valued at £20,435, and in 1873, 65,048 cwt., valued at £45,363. Of cocoa-nut oil the exports in 1850 were 32,785 cwt., valued at £35,035, and in 1873, 113,872 cwt., of the value of £141,818.

Trade and Commerce.—The trade of Ceylon shows a steady improvement. The earliest returns of imports and exports are those for 1825, which give the following figures:—Imports, £296,301; exports, £224,388; total, £510,689. The latest returns show that in 1874 the imports and exports together were valued at nearly ten millions, as against half a million in 1825, that is half a century ago. The figures are as follows:—

Year.	Imports.	Exports.	Total.
1835	£352,076	£109,268	£551,344
1845	1,495,127	583,100	2,078,227
1855	2,388,191	1,974,777	4,362,968
1865	5,022,179	3,565,157	8,587,336
1874	5,336,119	4,394,427	9,730,546

There has been a corresponding increase in the tonnage of shipping entered and cleared during the same period. The figures are as follows:—

1825	91,635 tons.
1835	145,182 ,
1845	423,370 „
1855	634,482 „
1865	1,150,840 „
1874	2,015,158 „

With the exception of a duty of one shilling per cwt. on plumbago, which is in lieu of the royalty to which the Crown was entitled on all plumbago as it came from the pits, there are no export duties; the duty on imports is five per cent. on the declared value, with some few exceptions, such as arms, wines, spirits, and grain, which are liable to special rates; paddy, or rice in husk, which pays 3d. a bushel; rice and other grain, 7d. a bushel; and machinery, paper, and a few other articles, which are free.

Banks.—Two English banking companies and one Indian bank have branches in Ceylon—the Oriental Bank Corporation, the Chartered Mercantile Bank of India, London, and China, and the Bank of Madras. The two chartered banks, the Oriental and the Chartered Mercantile Bank, have the privilege of issuing notes of five rupees and upwards in value. The Government in 1856 gave up this privilege, and left the paper currency of the island entirely in the hands of the banks, who pay to the Government, in lieu of stamp duty, one per cent. per annum on the average amount of notes in circulation, and are required to keep in reserve bullion equal to one-third of their issues. The bank notes are received at all the Government treasuries throughout the island, but the banks are bound to redeem them with specie after a notice of 60 days; this rule is only enforced when the Government requires a remittance of specie at some distant treasury. The note circulation has increased with the general improvement in the financial position of Ceylon. In 1854 it amounted to £131,000, of which £70,000 was represented by Government notes; in 1859 it amounted to £93,334, in 1864 to £259,631, in 1869 to £270,979, and in 1874 to £386,089. Since 1st January 1872 the rupee has been the sole standard of value in Ceylon, with decimal subdivisions, represented by bronze token pieces, which are taken as equivalent to $\frac{1}{100}$ th part of a rupee or 5 cents, $\frac{1}{200}$ th part of a rupee or one cent, $\frac{1}{400}$ th part of a rupee or half a cent, $\frac{1}{800}$ th part of a rupee or a quarter of a cent. All accounts are kept in rupees and cents. The Indian silver subsidiary coins are current,—the half rupee as 50 cents, the quarter rupee as 25 cents, and the two anna piece ($\frac{1}{4}$ th of a rupee) as 12½ cents. The rupee is the Company's silver rupee of India, of 180 grains weight and $\frac{1}{12}$ ths fineness.

Revenue and Expenditure.—The total revenue for 1874 was £1,241,558, the total expenditure £1,110,180. The principal heads of revenue are customs, £268,203; land sales, £67,795; land revenue, £80,822; tolls on roads and canals, £41,247; licensees (under which head is derived the revenue from the Government monopoly of the arrack trade), £173,305; stamps (including both general and postage), £105,239, of which about £20,000 is postal revenue; fines and forfeitures, £8440; sale of Government property, £133,323, of which about £70,000 is derived from the monopoly on salt; reimbursements, £30,000; interest on suitors' deposits invested in Indian Government securities and on balances in England, £13,600; miscellaneous, £44,633; pearl fishery, £9524; railway receipts, £221,168. Of the customs duties about £150,000 is derived from the import duty on grain, and of the land revenue about £70,000 is derived from the tithe on grain; it thus appears that about one-fifth of the total revenue of the island is derived from a tax on the daily food of the people. In defence of these burdens on food, it is urged that the importation of rice is rendered necessary, to a large extent, by the employment on the coffee estates of immigrant labourers from the south of India, who come over for the coffee season and return to India with their earnings, out of which they would contribute nothing to the revenue of Ceylon, if it were not for the tax on their imported food; and as regards the tithe on grain, that

this is the reserved rent of the Crown as supreme landlord. The monopoly of the arrack trade yields about £170,000. The very name of monopoly has an odious sound, but in the instances in which it exists in Ceylon it is difficult to see what mode of taxation would be less oppressive, and, as regards the arrack monopoly, there can be no doubt that its possession by the Government renders possible the exercise of an effectual check on the abuse of this intoxicant. The Government restricts distillation to certain licensed stills, which are left free to sell the spirit wholesale in open market, but the right to retail is granted only to certain persons and certain taverns. This right is sold by auction from year to year to taverns or groups of taverns, which are bound to retail pure arrack at not more than a certain price named in the conditions, and are subjected to stringent regulations for the prevention of drunkenness and the maintenance of order. In the management of this monopoly, revenue is a secondary consideration, and taverns are only allowed where they are absolutely required, that is, where their place, if they were not allowed, would be supplied by the illicit sale of arrack. The proper management of this monopoly has received much attention from the present governor, Sir W. H. Gregory, and he has been careful to enforce the observance of the principles which have always been supposed to govern this question. The monopoly of salt has been from time immemorial in the hands of the sovereign, and, as it prevails in Ceylon, is common to every country in the East; it seems to be the only expedient by which to obtain a minimum of taxation from classes incapable of bearing in any other shape an equitable share of the public burdens. Salt is produced at about 10d. per cwt. and sold at 4s. 8d. per cwt.

The principal heads of expenditure are as follows:—Salaries and office charges, £354,761; pensions, £41,000; revenue services, £24,000; hospitals, £16,000; education, £14,600; police and jails, £30,700; works and buildings, £21,000; roads, streets, bridges, and canals, £185,300; military. The returns of revenue and expenditure given above, do not represent the whole of the public revenue and expenditure of the island; there have to be added the returns from the municipalities and the local boards by which the road tax is collected. These figures are as follows for the year 1874:—

	Revenue.	Expenditure.
Colombo Municipality	£38,961	£38,708
Galle „	7,057	6,100
Kandy „	11,766	14,548
Provincial Road Committees—		
Western Province.....	35,087	28,468
North-Western Province...	9,213	6,130
Southern „ ..	9,554	8,046
Eastern „ ..	5,192	4,350
Northern „ ..	7,117	6,976
Central „ ..	16,937	9,319
North-Central „ ..	2,635	1,833
Total,.....	£143,519	£124,478

The returns of revenue from 1856 to the present time show a steady and rapid increase, and are a fair indication of the great advance which Ceylon is making. The revenue in 1856 was £504,174; it rose, year by year, till it reached £767,100 in 1860, and in 1865 it amounted to £978,462; it then fell somewhat owing to the cession by the Government to the municipalities of certain sources of revenue, but it rose in 1870 to £1,091,606, in 1871 to £1,121,679, in 1872 to £1,174,698, and in 1873 to £1,290,918. The revenue for 1874 in reality exceeded that of 1873, though it is only given as £1,241,558, which is the equivalent of rupees 1,32,43,288 at 1s. 10½d., at which the rupee is rated in the accounts for 1874, whereas in the previous year it was rated at 2s.

Tennent's *Ceylon*, 2 vols. 2d ed. 1859; *Reports to Ceylon Government by Service Tenants Commissioner*, 1870–1873; *Ceylon Government Blue Book*, 1874, and *Gazette*, 1875; *Children's Pali Dictionary*, 1875; *Fergusson's Ceylon Directory*, 1875 (J. F. D.)

CHABLIS, a town of France, on the Seray or Serein, in the department of Yonne, 10 miles east of Auxerre. It has a church, St Martin, of the 13th century, which is classed among the historical monuments of France; and it gives its name to a celebrated white wine produced in the neighbouring vineyards, of which the most esteemed are Clos, Valmur, Vaudesir, Bougureau, and Mont de Milieu. Population in 1872, 2270.

CHABRIAS, a celebrated Athenian general, who first assumed the command about the year 392 B.C. He defeated the Spartans at Ægina (388), and again at Naxos (376). With Iphicrates and Callistratus he commanded at Coreyra,

and repulsed Epaminondas before the walls of Corinth. In 366, together with Callistratus, he was accused of treachery in advising the surrender of Oropus to the Thebans, and was then, it is said, defended by Plato. His unpopularity on account of this charge, and also on account of his ostentation and luxuriousness, led him to accept a foreign command under Tachos, king of Egypt, who had revolted from the Persians. On the breaking out of the Social War (357), he, however, joined Chares in the command of the Athenian fleet. At the siege of Chios, his ship was disabled, but he refused to flee, and fell fighting bravely. He was famous for the invention of a manœuvre.

which consisted in receiving a charge on the left knee, with the spears of the front ranks pointed against the enemy and the shields resting on the ground.

CHADERTON, LAURENCE (1536-1640), a Puritan divine, was born at Lees Hall, in the parish of Oldham, Lancashire, September 14, 1536, being the second son of Edmund Chaderton, a gentleman of an ancient family, and a zealous Catholic. Under the tuition of Laurence Vaux, a priest, he became an admirable scholar. In 1562 he entered Christ's College, Cambridge, where, after a short time, he formally joined the Established Church, and was, in consequence, disinherited by his father. In 1567 he was elected a fellow of his college, and subsequently he was chosen lecturer of St Clement's Church, Cambridge, where he preached to admiring audiences for many years. So great was his reputation that when Sir Walter Mildmay refounded Emmanuel College in 1584, he chose Chaderton for the first master, and on his expressing some reluctance, declared that if he would not accept the office, the foundation should not go on. In the beginning of the reign of James I. Chaderton was appointed one of the five divines for managing the cause of the Puritans at the Hampton Court conference; and he was also one of the translators of the Bible. In 1613 he was created D.D. At this period he made provision for twelve fellows and above forty scholars, in Emmanuel College. Fearing that he might have a successor who held Arminian doctrines, he resigned the mastership in favour of Dr Preston, but survived him, and lived also to see the college presided over successively by Dr Sauerfort and Dr Holdsworth. He died November 1540 in the second month of his 105th year, according to his biographer Dr Dillingham. Dr Chaderton published a sermon preached at St Paul's Cross in 1578, and a treatise of his *On Justification* was printed by Anthony Thysius, professor of divinity at Leyden. Some other works by him on theological subjects remain in manuscript.

CHÆRONEIA, a Boeotian town situated on the Thermædon, a tributary of the Cephissus, on a plain which was on the borders of Phœcis, and was on the natural route for an army invading Boeotia on that side. It is celebrated in history as the scene of three great battles. In the first (447 B.C.) the Athenians were defeated by the Boeotians; in the second (388 B.C.) Philip defeated the confederate forces of the Athenians and Boeotians; and in the third (86 B.C.) Sulla defeated the generals of Mithridates. A colossal lion lately excavated near the site of the modern Kápurna marks the grave of the Boeotians who fell in the second of these engagements, and in the village itself are some remains of the ancient citadel, the Petraehus, and a theatre excavated out of the rock on which the citadel was built. Chæroneia was the birthplace of Phlarch.

CHIAFFINCH (*Fringilla celebs*), a Conirostral Bird, belonging to the family *Fringillidae* or Finches, and distinguished, in the male sex, by the deep greyish blue of its crown feathers, the sulphur yellow of its rump, the white of the wing coverts, so disposed as to form two conspicuous bars, and the reddish brown passing into vinous red of the throat and breast. The female is less conspicuous in its colouring than the male, and the young males resemble the females until after the first autumn moult, when they gradually assume the plumage of their sex. The chaffinch breeds early in the season, and its song may often be heard in February. Its nest, which is a model of neatness and symmetry, it builds on trees and bushes, preferring such as are overgrown with moss and lichens. It is chiefly composed of moss and wool, lined internally with grass, wool, feathers, and whatever soft material the locality affords. The outside consists of moss and lichens, and according to Selby, "is always accordant with the par-

ticular colour of its situation." When built in the neighbourhood of towns the nest is somewhat slovenly and untidy, being often composed of bits of dirty straw, pieces of paper and blackened moss; in one instance, near Glasgow, the author of the *Birds of the West of Scotland* found several postage-stamps thus employed. It lays four or five eggs of a pale purplish buff, streaked and spotted with purplish red. In spring the chaffinch is destructive to early flowers, and to young radishes and turnips just as they appear above the surface; in summer, however, it feeds principally on insects and their larvæ, while in autumn and winter its food consists of grain and other seeds. On the Continent of Europe the chaffinch is a favourite songbird, especially in Germany, where a cow has been known to be given in exchange for one of these birds, and where great attention is paid to its training. Its notes are clear and powerful, and, according to Beechstein, "seem almost to approach to words." The chaffinch is found throughout Europe and Western Asia, and has been observed as far west as the Azores. It is resident all the year in the warmer parts of this area, but migrates southward from Northern Europe on the approach of winter. It was at one time supposed that the females only migrated, and Linnaeus named the species *Calebs*, or "bachelor," in allusion to this alleged desertion of the males by their mates, which, however, does not appear to take place.

CHAGRES, a seaport of Colombia, in the state of Panama, situated on the northern side of the Isthmus of Panama, about 12 miles W.S.W. of Colon or Aspinwall, at the mouth of a river of its own name. Before the opening of the railway between Panama and Aspinwall in 1855 it was a place of very considerable importance; but it has now sunk into a very decadent and dilapidated condition, and the inhabitants, who are mainly negroes or half-castes, only amount to about 1000. The period of its greatest prosperity coincides with the great emigration from the United States to the Californian gold-fields, and the district on the left side of the river is still known as the American town. The chief facts in its history are its destruction by the buccaneers in 1671 and its capture by the English under Admiral Vernon in 1740.

CHALCEDON, or rather CALCIEDON, an ancient maritime town of Bithynia, in Asia Minor, called also Preecrastis and Colpusa, almost directly opposite Byzantium, to the south of the present town of Scutari. It was founded by a colony from Megara, on a site so obviously inferior to that which was within their view on the opposite shore, that it received from the oracle the name of "The City of the Blind." In its early history it shared the fortunes of Byzantium, was taken by the satrap Otanes, vacillated long between the Lacedæmonian and the Athenian interest, and at last fell into the hands of the kings of Bithynia, by the last of whom it was bequeathed to the Romans. It was taken and partly destroyed by Mithridates, but it recovered during the empire, and in 451 A.D. was the seat of the Fourth General Council, which condemned the Monophysites. It fell under the repeated attacks of the barbarian hordes, who crossed ever after having ravaged Byzantium, and it furnished an encampment to the Persians under Chosroes for about ten years after 616. Its ruin was completed by the Turks, who used it as a quarry from which to draw the building materials for Constantinople. The site is now occupied by the village of Kadi Keui, or "Village of the Judge," which contains a number of fine villas and a large Roman Catholic cathedral. At a short distance to the south are the ruins of Panteleion, or, as it is now called, Pandik, where Belisarius is said to have lived in retirement. A plain in the neighbourhood affords camping ground for the caravans after they leave Scutari.

CHALCIS. See EUBÆA.

CHALDEA. See BABYLONIA, vol. iii. p. 183.

CHALK (Ang.-Sax. *cealc*; Lat. *calx*, lime), an earthy limestone of the Upper Cretaceous group of rocks. It has a specific gravity of from 2.4 to 2.6, is rough to the touch, is friable, and presents an uneven fracture; it has an insipid taste, and adheres slightly to the tongue; it is usually white, and imparts its colour to surfaces over which it is rubbed. On microscopical examination, chalk is found to consist in the main of the minute shells of Foraminifera. In addition to calcium carbonate, chalk usually contains about 5 per cent. of water, with some free silica and ferric oxide, besides minor impurities. The red varieties of chalk may contain as much as 9.23 per cent. of silica, 9.6 per cent. of ferric oxide, and 1.42 per cent. of alumina (Clapham, *Chem. News*, 1862, vol. vi. p. 313.) Some of the red chalk of Norfolk gives, when treated with acids, an argillaceous residuum, which when air-dried has a weight equal to 9.3 per cent. that of the chalk taken, and has been found on analysis to consist of water, ferric oxide, and alumina, with a small proportion of magnesia and potash (Church, *Chem. News*, 1875, vol. xxxi. p. 199.)

The flooding of streams that flow through chalky ground is almost unknown, since chalk is very porous, and will when dry take up nearly one-third of its bulk of water (Ansted and Miller); and in some districts where chalk is the surface-rock, the heaviest showers are absorbed as soon as they fall. During the summer months, however, most of the rainfall penetrates only a few feet downwards, and is consequently imbibed by vegetation or evaporated; for though chalk is highly absorbent, its fine and close texture does not allow of the free permeation of water. Occasionally, lower-lying beds of chalk have been drained, whilst higher levels have remained charged with moisture. The circulation of water in chalk strata is due, in fact, not so much to general percolation in the mass, as to its flow either through fissures or, as in the case of deep-seated and but little disturbed and creviced beds, along planes of stratification. As a storehouse of water the chalk formation is of great importance, the artesian wells of London and many other places being supplied directly or indirectly from it. Where chalk forms the surface of the land, the yield of water may be very large, as at the Tring cutting of the North-Western Railway, where it amounted to upwards of a million gallons a day. Chalk is much used as a dressing for land deficient in lime, and is of special value where the soil consists of a stiff wet clay. The effect of the addition of chalk is to render the soil better able to retain moisture, and to improve its texture. It is generally most efficacious when used in moderate quantity every six or seven years. The renewal of the supply of chalk is necessary owing to its removal from the surface by solution and by the undermining action of earthworms. The chalk is not ploughed into the land till it has been exposed to frost, which breaks it up into small squarish fragments. In the Lincolnshire wolds, the process of chalking, in conjunction with boning and manuring, has brought about a great improvement in the soil. In Dorsetshire the land is usually chalked once in twenty years. The chalk is spread on the ground in large lumps, which crumble down under the influence of the weather; or it may be burnt and applied as lime. For sandy soils, on which it acts as a cement, chalk is best adapted when marly in character. On poor chalky ground, the sainfoin (*Onobrychis sativa*), a plant which flourishes in calcareous soils and is an excellent fodder for cattle, has been cultivated with great success; and the herbage of the chalk downs of Sussex, Wilts, and other counties of England, affords good pasture for sheep.

Chalk is employed medicinally as an antacid and mild astringent, either alone, or together with other astringents, or combined with mercury as *hydrargyrum cum creta*, but never in the crude state. As none of the salts it forms is purgative, it is a valuable remedy in diarrhoea. Externally, prepared chalk is used as a dessiccant, and as a protective application for ulcers and burns, and in intertrigo and other affections of the skin. When taken for a prolonged period, chalk is apt to form concretions in the stomach, for want of acid sufficient to dissolve it.

Chalk is rarely hard enough to be used in any kind of building. When burnt to lime it serves the same purposes as stone lime, but on account of its more rapid absorption of carbonic acid gas, it is not so fit for general use as the latter, except when fresh from the kiln. Chalk is employed in the manufacture of cements and of carbonate of soda, in the preparation of carbonic acid gas, and in many other chemical processes; also for making paints, crayons, and tooth-powder. *Whiting* or *Spanish white*, used to polish glass and metal, is purified chalk prepared by triturating common chalk with a large quantity of water, which is then decanted and allowed to deposit the finely-divided particles it holds in suspension.

Black chalk or *drawing slate* is a soft carbonaceous schist, which gives a black streak, so that it can be used for drawing or writing. *Brown chalk* is a kind of amber. *Red chalk* or *reddle* is an impure earthy variety of hematite. *French chalk* is a soft variety of steatite, a hydrated silicate of magnesium.

See J. Prestwich, *The Water-bearing Strata of London*, p. 57, sqq. (London, 1851); J. A. Clarke in *Journ. Roy. Agric. Soc.*, vol. xii. p. 331 (1851); Caird, *English Agriculture in 1850 and 1851*, p. 61 (London, 1852).

CHALLONER, RICHARD (1691–1781), an eminent Roman Catholic prelate, born at Lewes, Sussex, 29th September 1691. After the death of his father, who was a rigid Dissenter, his mother sought refuge with some Roman Catholic families, the consequence being that the son was brought up in their religion, chiefly at the seat of Mr Holman at Warkworth, Northamptonshire, where the Rev. John Gother, a celebrated controversialist, officiated as chaplain. In 1704 he was sent to the English College at Douay, where he was ordained a priest, took his degrees in divinity, and was appointed professor in that faculty. In 1730 he was sent on the English mission and stationed in London. The controversial treatises that he now published in rapid succession attracted much attention, particularly his *Catholic Christian Instructed*, which was prefaced by a witty reply to Dr Conyers Middleton's *Letter from Rome, showing an exact conformity between Popery and Paganism*. Middleton is said to have been so irritated that he endeavoured to put the penal laws in force against his antagonist, who prudently withdrew from London until the commotion subsided. On 29th January 1741, Challoner was raised to the episcopal dignity at Hammersmith, by the title of bishop of Debra, *in partibus infidelium*, and nominated coadjutor, *cum jure successionis*, to Bishop Petre, Vicar-Apostolic of the London district. Accordingly, on the decease of that prelate in 1758, Challoner succeeded to the Vicariate-Apostolic. He resided principally in London, but was obliged to retire into the country during the "No-Popery" riots of 1780. Soon afterwards he died, on January 12, 1781, and was buried at Milton, Berkshire. Bishop Challoner was the author of numerous controversial and devotional works, which have been frequently reprinted and translated into various languages. He compiled the *Garden of the Soul*, which continues to this day to be the most popular manual of devotion among English-speaking Roman Catholics; and he revised an edition of the Donay version of the Scriptures.

(1749–50), correcting the language and orthography, which in many places had become obsolete. Of his historical works the most valuable is one which was intended to be a Roman Catholic antidote to Foxe's well-known martyrology. It is entitled *Memoirs of Missionary Priests and other Catholics of both Sexes who suffered Death or Imprisonment in England on account of their Religion, from the year 1577 till the end of the reign of Charles II.*, 2 vols. 1741; reprinted in 1803. Bishop Challoner also published anonymously, in 1745, the lives of English, Scotch, and Irish saints, under the title of *Britannia Sancta*.

CHALMERS, ALEXANDER (1759–1834), was born in Aberdeen. He was educated as a doctor, but gave up this profession for literature. His first productions were contributions to London periodicals, and he was for some time editor of the *Morning Herald*. Besides editions of the works of Shakespeare, Beattie, Fielding, Johnson, Warton, Pope, Gibbon, Bolingbroke, and others, he published *A General Biographical Dictionary* in 32 vols. (1812–1817); a *Glossary to Shakspeare*; an edition of Shakspeare; and the *British Essayists*, commencing with the *Tatler* and ending with the *Observer*, with biographical and historical prefaces and a general index.

CHALMERS, GEORGE (1742–1825), an antiquarian and political writer of considerable eminence, was born at Fochabers, a village in the county of Moray, in the year 1742. His father, James Chalmers, was a grandson of George Chalmers of Pittensear, a small estate in the parish of Lhanbryde, now St Andrews-Lhanbryde, in the same county, possessed by the main line of the family from about the beginning of the 17th to the middle of the 18th century. After completing the usual course at King's College, Aberdeen, young Chalmers studied law in Edinburgh for several years. Two uncles on the father's side having settled in America, he visited Maryland in 1763, with the view, it is said, of assisting to recover a tract of land of some extent about which a dispute had arisen, and was in this way induced to commence practice as a lawyer at Baltimore, where for a time he met with much success. Having, however, espoused the cause of the Royalist party on the breaking out of the American war of Independence, he found it expedient to abandon his professional prospects in the New World, and return to his native country. For the losses he had sustained as a colonist he received no compensation, and several years elapsed before he obtained an appointment that placed him in a state of comfort and independence.

In the meantime Chalmers applied himself with great diligence and assiduity to the investigation of the history and establishment of the English colonies in North America; and enjoying free access to the state papers and other documents preserved among what were then termed the plantation records, he became possessed of much important information. His work entitled *Political Annals of the present United Colonies from their Settlement to the Peace of 1763*, 4to, London, 1780, was to have formed two volumes; but the second, which should have contained the period between 1688 and 1763, never appeared. The first volume, however, is complete in itself, and traces the original settlement of the different American colonies, and the progressive changes in their constitutions and forms of government as affected by the state of public affairs in the parent kingdom. Independently of its value as being compiled from original documents, it bears evidence of great research, and has been of essential benefit to later writers. Continuing his researches, he next gave to the world *An Estimate of the Comparative Strength of Britain during the Present and Four Preceding Reigns*, Lond. 1782, which passed through several editions. At length, in August 1786, Chalmers, whose sufferings as a Royalist

must have strongly recommended him to the Government of the day, was appointed chief clerk to the committee of Privy Council on matters relating to trade, a situation which he retained till his death in 1825, a period of nearly forty years. As his official duties made no great demands on his time, he had abundant leisure to devote to his favourite studies,—the antiquities and topography of Scotland having thenceforth special attractions for his busy pen.

Besides biographical sketches of Do Foe, Sir John Davics, Allan Ramsay, Sir David Lyndsay, Churchyard, and others, prefixed to editions of their respective works, Chalmers wrote a life of Paine, the author of the *Rights of Man*, which he published under the assumed name of Francis Oldys, A.M., of the University of Pennsylvania; and a life of Ruddiman, in which considerable light is thrown on the state of literature in Scotland during the earlier part of the last century. His life of Queen Mary, in two quarto volumes, was first published in 1818. It is founded on a MS. left by Whitaker the historian of Manchester; but Chalmers informs us that he found it necessary to rewrite the whole. The history of that ill-fated queen occupied much of his attention, and his last work, *A Detection of the Love-Letters lately attributed in Hugh Campbell's work to Mary Queen of Scots*, is an exposure of an attempt to represent as genuine some fictitious letters said to have passed between Mary and Bothwell, which had fallen into deserved oblivion. In 1797 appeared his *Apology for the Believers in the Shakespeare Papers which were exhibited in Norfolk Street*, followed by other tracts on the same subject. These contributions to the literature of Shakespeare are full of curious matter, but on the whole display a great waste of erudition, in seeking to show that papers which had been proved forgeries might nevertheless have been genuine. Chalmers also took part in the Junius controversy, and in *The Author of Junius Ascertained, from a Concatenation of Circumstances amounting to Moral Demonstration*, Lond. 1817, 8vo, sought to fix the authorship of the celebrated letters on Hugh Boyd. In 1824 he published *The Poetical Remains of some of the Scottish Kings, now first collected*; and the same year he edited and presented as a contribution to the Bannatyne Club *Robene and Makyne and the Testament of Cresseid*, by Robert Henryson. His political writings are equally numerous. Among them may be mentioned *Collection of Treaties between Great Britain and other Powers*, Lond. 1790, 2 vols. 8vo; *Vindication of the Privileges of the People in respect to the Constitutional Right of Free Discussion, &c.*, Lond. 1796, 8vo, published anonymously; *A Chronological account of Commerce and Coinage in Great Britain from the Restoration till 1810*, Lond. 1810, 8vo; *Opinions of Eminent Lawyers on various points of English Jurisprudence, chiefly concerning the Colonies, Fisheries, and Commerce of Great Britain*, Lond. 1814, 2 vols. 8vo; *Comparative Views of the State of Great Britain before and since the War*, Lond. 1817, 8vo.

But Chalmers's greatest work is his *Caledonia*, which, however, he did not live to complete. The first volume appeared in 1807, and is introductory to the others. It is divided into four books, treating successively of the Roman, the Pictish, the Scottish, and the Scoto-Saxon periods, from 80 to 1306 A.D. In these we are presented, in a condensed form, with an account of the people, the language, and the civil and ecclesiastical history, as well as the agricultural and commercial state of Scotland during the first thirteen centuries of our era. Unfortunately the chapters on the Roman period are entirely marred by the author's having accepted as genuine Bertram's forgery *De Situ Britanniae*; but otherwise his opinions on controverted topics are worthy of much respect, being founded on a laborious investigation of all the original authorities that were accessible to him. The style both of both and

of the succeeding volumes is redundant, the scholarship is often defective, and hastily-drawn conclusions are asserted with the utmost confidence in their accuracy; yet, notwithstanding all these drawbacks, such were the industry and perseverance of Chalmers that his *Caledonia* contains a mass of information on all subjects connected with early Scottish history and topography that has been of the highest value to subsequent writers. The second volume, published in 1810, gives an account of the seven south-eastern counties of Scotland—Roxburgh, Berwick, Haddington, Edinburgh, Linlithgow, Peebles, and Selkirk, each of them being treated of as regards name, situation and extent, natural objects, antiquities, establishment as shires, civil history, agriculture, manufactures and trade, and ecclesiastical history. In 1824, after an interval of fourteen years, the third volume appeared, giving, under the same headings, a description of the seven south-western counties—Dumfries, Kirkcudbright, Wigtown, Ayr, Lanark, Renfrew, and Dumbarton. In the preface to this volume the author states that the materials for the history of the central and northern counties were collected, and that he expected the work would be completed in two years. This expectation, however, was not destined to be realized. It is much to be regretted that, instead of all but wasting his time on profitless and acrimonious controversies about Shakespearian forgeries and the character of Queen Mary, Chalmers did not direct his whole energies to his *magnum opus*, and give to the world the matured fruits of all the labour he had bestowed on it; for it is on *Caledonia* that his fame must chiefly rest.

While thus fully occupied, Chalmers had for many years been engaged in laying the foundation for other works of a not less important and laborious nature. One of these is said to have been a history of Scottish poetry, another, a history of printing in Scotland. Each of them he thought likely to extend to two large quarto volumes, and on both he expended an unusual amount of enthusiasm and energy. He had also prepared for the press an elaborate history of the life and reign of David I. In his later researches he was assisted by his nephew James, son of Alexander Chalmers, writer in Elgin.

George Chalmers died at his house, James Street, Buckingham Gate, London, May 31, 1825, after a few days' illness, in the eighty-third year of his age. His valuable and extensive library he bequeathed to his nephew, at whose death in 1841 it was sold and dispersed. Chalmers was a member of the Royal and Antiquarian Societies of London, an honorary member of the Antiquarian Society of Scotland, and a member of other learned societies. In private life he was undoubtedly an amiable man, although the dogmatic tone that disfigures portions of his writings procured him many opponents. He is besides chargeable with a want of taste, which appears too prominently in his keen attempts to silence, at all hazards, those whom he considered the detractors of Mary. Among his avowed antagonists in literary warfare the most distinguished were Malone and Steevens, the Shakspeare editors; Mathias, the author of the *Pursuits of Literature*; Dr Jamieson, the Scottish lexicographer; Pinkerton, the historian; Dr Irving, the biographer of the Scottish poets; and Dr Currie of Liverpool. But with all his failings in judgment, Chalmers was a valuable writer. He uniformly had recourse to original sources of information; and he is entitled to great praise for his patriotic and self-sacrificing endeavours to illustrate the history, literature, and antiquities of his native country. (J. M'D.)

CHALMERS, DR. THOMAS (1780–1847), a distinguished Scottish divine, was born at Anstruther in Fifeshire, on the 17th March 1780. He was early destined to the church, and while only eleven years old was enrolled as a student

in the university of St Andrews. Having completed his collegiate course, in which he devoted himself almost exclusively to the study of mathematics, in January 1799 he was licensed as a preacher of the gospel by the presbytery of St Andrews. Instead of entering at once on the duties of his profession, he spent the two following winters in Edinburgh, attending the lectures of Professors Stewart, Playfair, Robison, and Hope. In May 1803 he was ordained as minister of Kilmany, a small parish in Fife-shire, about nine miles from St Andrews. During the preceding winter he had acted as assistant to Mr Vilant, professor of mathematics in the university of that city, who for many years had been laid aside by ill health. The novelty, however, of his method, and the singular enthusiasm that he exhibited and excited were distasteful to those attached to the old routine of university education; and at the close of the session he was informed that his further services would not be required. Indignant at the fancied injustice thus done him, he adopted the singular expedient of opening mathematical classes of his own during the succeeding winter, which, though discountenanced in every way by the university authorities, many of the students were attracted to attend. The winter of 1803–4 was a very busy and exciting one. During the week he taught three classes in St Andrews, and prepared and delivered there a course of lectures on chemistry, largely illustrated by experiments,—appearing at the same time in the pulpit of Kilmany every Sunday. Having sufficiently redeemed his reputation by the great success which attended them, his mathematical classes were not resumed. The lectures on chemistry were frequently redelivered in his own and in many adjoining parishes, to the surprise and delight of many rural audiences. In 1805 the chair of mathematics in Edinburgh became vacant, and he appeared, but unsuccessfully, as a candidate. In 1808 he published an *Inquiry into the Extent and Stability of National Resources*, a treatise originated by the alarm which Buonaparte's commercial policy had created in Britain, and intended to elucidate some of those questions in political economy which the existing state of affairs had raised. He was preparing a new edition of this work when a series of domestic bereavements, and a severe illness that brought him to the brink of the grave, and laid him aside from all duty for upwards of a year, turned his thoughts and life into a new channel. Dr Brewster had invited him to become a contributor to the *Edinburgh Encyclopædia*; at his own request the article Christianity had been assigned to him, and he was now engaged in preparing it. In studying the credentials of Christianity, he received a new impression of its contents. A sustained but abortive effort to attain that pure and heavenly morality which the Gospel of Christ requires led on to that great spiritual revolution the nature and progress of which his journal and letters enable us to trace with such distinctness. When he resumed his duties, an entire change in the character of his ministry was visible to all. The report of discourses so earnest and eloquent as those now delivered, and of household visitations conducted with such ardent zeal, soon spread beyond the limits of his own neighbourhood. His reputation as an author received at the same time a large accession by the publication in a separate form of his article on Christianity, as well as by several valuable contributions to the *Edinburgh Christian Instructor* and the *Eclectic Review*. So strong, however, at that time was the public bias against those evangelical doctrines which he had embraced, that when a vacancy occurred in Glasgow, and his friends brought him forward as a candidate, it was only after extraordinary efforts, and by a narrow majority, that his election was carried in the town-council.

In July 1815 he was formally admitted as minister of

the Tron church and parish. A blaze of unparalleled popularity at once broke around him as a preacher. A series of discourses which he had preached on the connection between the discoveries of astronomy and the Christian revelation were published in January 1817. Never either before or since has the same reception been given to any volume of sermons in our language. Within a year, nine editions and 20,000 copies of the volume were in circulation. Soon after its appearance he visited London, and occupied for the first time one or two of the pulpits of the metropolis. The crowds were enormous, the applause loud and universal. "All the world," writes Mr Wilberforce, "wild about Dr Chalmers." His extraordinary popularity remained undiminished during the eight years that he remained in Glasgow.

His preparation for the pulpit, however, formed but a small part of his labours. In visiting his parish, which contained a population of about 11,000 souls, he speedily discovered that nearly a third of them had relinquished all connection with any Christian church, and that their children were growing up in ignorance and vice. The appalling magnitude of the evil, and the certainty of its speedy and frightful growth, at once arrested and engrossed him. To devise and execute the means of checking and subduing it became henceforth one of the ruling passions of his life. Attributing the evil to the absence of those parochial influences, educational and ministerial, which wrought so effectually for good in the smaller rural parishes, but which had not been brought to bear upon the overgrown parishes of our great cities, from all spiritual oversight of which the members of the Establishment had retired in despair, his grand panacea was to revivify, remodel, and extend the old parochial economy of Scotland. Taking his own parish as a specimen, and gauging by it the spiritual necessities of the city, he did not hesitate to publish it as his conviction that not less than twenty new churches and parishes should immediately be erected in Glasgow. All, however, that he could persuade the town-council to attempt was to erect a single additional one, to which a parish containing no fewer than 10,000 souls was attached. This church, built at his suggestion, was offered to him and accepted, in order that he might have free and unimpeded room for carrying out his different parochial plans.

In September 1819 he was admitted as minister of the church and parish of St John's. The population of the parish was made up principally of weavers, labourers, factory workers, and other operatives. Of its 2000 families, more than 800 had no connection with any Christian church. The number of its uneducated children was countless. In this, as in his former parish, Dr Chalmers's first care and efforts were bestowed upon the young. For their week-day instruction, two commodious school-houses were built, four well-qualified teachers were provided, each with an endowment of £25 per annum; and at the moderate school-fees of 2s. and 3s. per quarter, 700 children had a first-rate education supplied. For the poorer and more neglected, between forty and fifty local sabbath schools were opened, in which more than 1000 children were taught. The parish was divided into 25 districts, embracing from 60 to 100 families, over each of which an elder and a deacon were placed—the former taking the oversight of their spiritual, the latter of their temporal interests. Over the whole of this complicated parochial apparatus Dr Chalmers presided, watching, impelling, controlling every movement. Nor was his work that of mere superintendence. He visited personally all the families, completing his round of them in about two years, and holding evening meetings, in which he addressed those whom he had visited during the week. Many families were thus reclaimed to the habit of church-going,

and many individuals deeply and enduringly impressed by the sacred truths of Christianity.

The chief reason why Dr Chalmers removed from the Tron parish to that of St John's was that he might have an opportunity of fairly testing the efficacy of the old Scottish method of providing for the poor. At this period there were not more than 20 parishes north of the Forth and Clyde in which there was a compulsory assessment for the poor. The English method of assessment, however, was rapidly spreading over the southern districts of Scotland, and already threatened to cover the whole country. Dr Chalmers dreaded this as a great national catastrophe. Having studied in its principles, as well as in its results, the operation of a compulsory tax for the support of the poor, he was convinced that it operated prejudicially and swelled the evil it meant to mitigate. It was said, however, that though the old Scotch method of voluntary contributions at the church door administered by the kirk-session was applicable to small rural parishes, it was inapplicable to the large and already half-pauperized parishes of our great cities. Dr Chalmers asked the magistrates of Glasgow to commit the entire management of the poor of the parish of St John's into his own hands, and he undertook to refute that allegation. He was allowed to try the experiment. At the commencement of his operations, the poor of this parish cost the city £1400 per annum. He committed the investigation of all new applications for relief to the deacon of the district, who had so small a number of families in charge, that by spending an hour among them every week, he became minutely acquainted with their character and condition. By careful scrutiny of every case in which public relief was asked for, by a summary rejection of the idle, the drunken, and the worthless, by stimulating every effort that the poor could make to help themselves, and when necessary, aiding them in their efforts, a great proportion of these new cases were provided for without drawing upon the church-door collections; and such was the effect of the whole system of Christian oversight and influence, prudently and vigorously administered, that in four years the pauper expenditure was reduced from £1400 to £280 per annum.

At the commencement of his ministry in St John's, Dr Chalmers began a series of quarterly publications on *The Christian and Civic Economy of Large Towns*, devoted to the theoretic illustration of the various schemes of Christian usefulness which he was carrying on,—presenting himself thus to us as at once their skilful deviser, their vigorous conductor, their eloquent expounder and advocate. But the fatigues of so toilsome a ministry began to exhaust his strength; and he was already longing to exchange the personal for the literary labours of his profession, when the vacant chair of moral philosophy in the university of St Andrews was offered to him. This offer, the seventh of the same kind that had been made to him during his eight years' residence in Glasgow, he accepted, entering on his new duties in November 1823, and devoting the next four years of his life to their fulfilment. Hitherto metaphysics and ethics had been taught conjointly by the professors of moral science in the Scotch colleges, while, in teaching the latter, allusions to the peculiar doctrines of Christianity had generally and often carefully been avoided. Looking upon mental philosophy as belonging properly to another chair, Dr Chalmers confined his prelections to the philosophy of morals, entering at large upon the duties man owes to God as well as those he owes to his fellow-men, endeavouring throughout to demonstrate the insufficiency of natural religion to serve any other purpose than that of a precursor of Christianity. Many of his lectures, as remodelled afterwards and transferred to the theological chair, are to be found now in the first and second volumes

of his works. In the purely ethical department, the discussions in which he made important and original contributions to the science are those occupied with the place and functions of volition and attention, the separate and undivided character of the moral sentiments, and the distinction between the virtues of perfect and imperfect obligation. It was not so much, however, for their scientific speculations that his lectures in the moral philosophy class-room were distinguished, as for that fervour of professional enthusiasm with which they were delivered, and which proved so healthfully contagious. Beyond the intellectual impulse thus communicated, his frequent references to the great doctrines of Christianity, and still more the force of his inviting example, kindled to a very remarkable degree the religious spirit among the students of St Andrews; and not a few of them—including many men who have since highly distinguished themselves—were led thereby to consecrate their lives to missionary labour.

In November 1828, Dr Chalmers was transferred from the chair of moral philosophy in St Andrews to that of theology in Edinburgh. In this wider theatre he was enabled to realize all his favourite ideas as to the best methods of academical instruction. To the old practice of reading to his students a set of carefully prepared lectures he added that of regular *viva voce* examination on what was thus delivered, and introduced besides the use of textbooks, communicating through them a large amount of information; and coming into the closest and most stimulating contact with his pupils, he attempted to combine the different systems pursued in the English and the Scottish universities. In the professorial chair there have been many who, with larger stores of learning, have conducted their students to greater scientific proficiency; but none have ever gone beyond him in the glowing impulse, intellectual, moral, and religious, that he conveyed into the hearts of the ardent youths who flocked around his chair; and to that spirit with which he so largely impregnated the young ministerial mind of Scotland, may, to a large extent, be traced the Disruption of the Scottish Established Church.

The leisure for literary labour which professorial life afforded was diligently improved. At St Andrews he resumed the work which his departure from Glasgow had suspended, and in 1826 published a third volume of the *Christian and Civic Economy of Large Towns*. This was followed in 1827 by his treatise on the *Use and Abuse of Literary and Ecclesiastical Endowments*, the ablest defence of endowments in our language, a work which itself would have won celebrity for its author. For many years his chief ambition had been to complete a treatise on political economy, a science which had been a favourite one from youth. In St Andrews, besides his ordinary course on ethics, he had opened a class for instruction in this science, and had been delighted to find how attractive it had proved. As soon as he had got through his first course of theological lectures in Edinburgh, he resumed this subject, and embodied the reflections and preparations of many years in a work on *Political Economy*, published in 1832. Many of the particular doctrines of this work have not met with general acceptance. The public mind, however, has been gradually coming round to a belief in that great truth which this volume was mainly intended to enforce,—that a right moral is essential to a right economic condition of the masses,—that character is the parent of comfort. His work on *Political Economy* was scarcely through the press, when, on invitation from the trustees of the earl of Bridgewater, Dr Chalmers was engaged on a treatise *On the Adaptation of External Nature to the Moral and Intellectual Constitution of Man*, which appeared in 1833. Literary honours, such as were never united previously in the person of any Scottish ecclesiastic, crowned these labours. In

1834 he was elected fellow of the Royal Society of Edinburgh, and was soon after made one of its vice-presidents. In the same year he was elected corresponding member of the Royal Institute of France, and in 1835 the university of Oxford conferred on him the degree of D.C.L.

Hitherto Dr Chalmers had taken but little part in the public business of the church. He had given some effective help in the prosecution of two measures—the one for the abolition of pluralities, and the other for the improvement of theological education. The death of Dr Andrew Thomson, who had long been the able leader of the Evangelical party, and the obtaining by that party of the ascendency, called him to lead the counsels and doings of the church. One of the earliest acts of the General Assembly of 1834, the first in which the Evangelical party had the majority, was to place Dr Chalmers at the head of a committee appointed to promote the extension of the church. In this office he had a double duty to discharge—to solicit the Government to make a grant out of the public revenue, and to stimulate the friends of the church by their own voluntary efforts to meet the spiritual necessities of the country. In both departments extraordinary efforts were made, but with very different results. The Whig Government, insecure in its hold of power, and dependent to some extent on the political assistance of the Scottish Dissenters, could be induced to do nothing beyond appointing a committee of inquiry, which led to no practical result. It was otherwise when Dr Chalmers appealed to the country. That appeal was made with singular ardour and eloquence. When circulars, pamphlets, and reports had done their uttermost, he made a tour through a large part of Scotland, addressing the various presbyteries and holding public meetings in the most populous districts. Year after year swelled the fund that these efforts created, till at last in 1841, when he resigned his office as convener of the Church Extension Committee, he had to announce that in seven years upwards of £300,000 had been contributed to this object, and 220 new churches had been built.

This great movement on behalf of church extension was finally checked by another in which Dr Chalmers was destined to play a still more conspicuous part. In 1834, the General Assembly, after declaring it to be a fundamental principle of the church that “no minister shall be intruded into any parish contrary to the will of the congregation,” had enacted that in every instance the dissent of the majority of the male heads of families, being communicants, should be a bar to the settlement of a minister. This Act, commonly called the Veto Law, was based upon the old constitutional practice of the “call,” in which the people invited the minister to undertake the pastoral office, on which invitation alone the spiritual act of ordination was grounded. The church believed herself to possess the power of determining what kind and amount of popular concurrence was necessary before the pastoral tie was formed by ordination. She had often exercised that power to the effect of setting aside the nominee of the patron. When invited in such instances to interfere, the civil courts had refused, on the ground that the church was acting within the limits of her acknowledged authority. In other instances the civil courts had often reviewed decisions of the church courts, but only with a view of regulating the title to the benefice. But now the power of the church to pass such a law as that of the Veto was challenged, and the civil courts claimed a right not only to regulate the destination of the benefice, but to control and overrule the decisions of the church. In the parish of Auchterarder, containing a population of 3000 souls, only two individuals signed the call, while 287 out of 300 dissented; but in an action raised at the instance of the presentee, the Court of Session decided that his rejection by

the church was illegal. This decision the House of Lords, on appeal to it, confirmed,—Lords Brougham and Cottenham, in delivering judgment, stating it expressly to be their opinion that in settling a minister the church had no legal right to look beyond his qualification as to “life, literature, and morals.” In this decision, as involving a forfeiture of the benefice, the church acquiesced, declaring at the same time her intention, for her own spiritual objects, to interpret for herself the statutes which established her, and announcing her unaltered purpose to protect her congregations from the intrusion of unacceptable ministers. It speedily appeared that she was not to be permitted to carry out these resolutions if the Court of Session could prevent. The presbytery of Dunkeld rejected a licentiate presented by the Crown to the parish of Lethendy on the ground of his having been vetoed by the people. The Crown acquiesced and issued a new presentation. At the instance of the first presentee the Court of Session interdicted the presbytery from ordaining the second. The church ordered the presbytery to proceed with the ordination. It did so, and was summoned in consequence to the bar of the civil court, solemnly rebuked, and informed that in the next instance of such disregard by the church of the interdict of the civil court imprisonment would be the punishment. In the parish of Marnoch, with a population of 2800 souls, only one individual signed the call; an overwhelming majority dissented; but in defiance of the law of the church, and in obedience to the Court of Session, the presbytery of Strathbogie, by a majority of 7 to 3, resolved to proceed to the ordination. To prevent this ordination the church suspended the seven ministers who formed the majority. The Court of Session not only annulled that suspension and prohibited the church from intimating or executing it, but interdicted all ministers from preaching or administering any of the sacraments within any of the parishes of the seven suspended clergymen. The church held such interference as a violation of her spiritual independence, and proceeded as if no such sentence of the civil court had been passed,—many of the most distinguished ministers, Dr Chalmers and Dr Gordon among the rest, preaching in those parishes in the face of interdicts served on them personally. The seven suspended clergymen treated in the same way the supreme ecclesiastical authority, and on the 21st January 1841, in opposition to an express order of the General Assembly, consummated the ordination. By the following General Assembly these clergymen were deposed from the office of the ministry. The Court of Session immediately thereafter pronounced the deposition null and void. Other like instances occurred. The collisions between the two supreme courts became frequent and most unseemly. Matters were running into inextricable confusion. The church appealed to the Government to interfere. At first the Whigs were in power, but they declined to interfere. In 1841, Sir Robert Peel was placed at the head of a Government strong enough to have applied the remedy, and the hopes of the church were excited. Still no measure was introduced. Under the guidance of Dr Chalmers the church pursued her course with steady unfaltering step; but she was not prepared to prolong the controversy indefinitely. Denying the right of the Court of Session to act as it had done, she freely conceded to the legislature the right of determining on what terms she held her temporalities; and if, fairly appealed to, the legislature declared that she held them on condition of rendering such obedience to the civil courts as they now required, she felt that she had no alternative but either to renounce her own principles or relinquish the temporalities. At a solemn convocation held in November 1842 a large number of ministers signed and published a declaration that if no measure of relief were

granted they would resign their livings. Up to the last, however, it was not believed that any very extensive secession would take place. In January 1843, the Government not only refused to grant the protection the church required, but put a final and peremptory negative on her claims of spiritual independence. And in March the House of Commons did the same by a large majority,—the Scotch members, however, voting in the proportion of more than two to one in her favour. The controversy was now closed, and it remained only for those clergymen who felt that they could not with a good conscience submit to the civil restraint imposed upon the church to adopt the only expedient now left to them and retire from the Establishment. On the 18th May 1843, 470 clergymen withdrew from the General Assembly and constituted themselves into the Free Church of Scotland, electing Dr Chalmers as their first moderator.

For two years previous to this final step, Dr Chalmers had foreseen the issue, and in preparation for it had drawn up a scheme for the support of the outgoing ministers. For a year or two afterwards the establishment and extension of that fund, to which the Free Church owes so much of her stability, engaged a large share of his attention. He then gradually withdrew from the public service of the church, occupying himself with his duties as principal of the Free Church College, and in perfecting his *Institutes of Theology*. In May 1847, he was summoned before a committee of the House of Commons to give evidence regarding that refusal of sites for churches in which a few of the landed proprietors of Scotland who were hostile to the Free Church were still persisting. He returned from London in his usual health, and after a peaceful Sabbath (May 30) in the bosom of his family at Morningside, he bade them all good night. Next morning, when his room was entered and the curtains of his bed withdrawn, he was found half erect, his head leaning gently back upon the pillow, no token of pain or struggle, the brow and hand when touched so cold as to indicate that some hours had already elapsed since the spirit had peacefully departed.

During a life of the most varied and incessant activity, spent much too in society, Dr Chalmers scarcely ever allowed a day to pass without its medium of composition. He had his faculty of writing so completely at command that at the most unseasonable times, and in the most unlikely places, he snatched his hour or two for carrying on his literary work. He was methodical indeed in all his habits, and no saying passed more frequently from his lips than that punctuality is a cardinal virtue. His writings now occupy more than 30 volumes. He would permanently perhaps have stood higher as an author had he written less, or had he indulged less in that practice of reiteration into which he was so constantly betrayed by his anxiety to impress his ideas upon others. It would be premature to attempt to estimate the place which his writings will hold in the literature of our country. We may briefly indicate, however, some of the original contributions for which we are indebted to him. As a political economist he was the first to unfold the connection that subsists between the degree of the fertility of the soil and the social condition of a community, the rapid manner in which capital is reproduced (see Mill's *Political Economy*, vol. i. p. 94), and the general doctrine of a limit to all the modes by which national wealth may accumulate. He was the first also to advance that argument in favour of religious establishments which meets upon its own ground the doctrine of Adam Smith, that religion like other things should be left to the operation of the natural law of supply and demand. In the department of natural theology and the Christian evidences, he ably advocated that method of reconciling the Mosaic narrative with the indefinite antiquity of the globe which Dr Buckland has advanced in his *Bridgewater Treatise*, and which Dr Chalmers had previously communicated to that author. His refutation of Hume's objection to the truth of miracles is perhaps his intellectual *chef d'œuvre*, and is as original as it is complete. The distinction between the laws and dispositions of matter, as between the ethics and objects of theology, he was the first to indicate and enforce. And it is in his pages that the fullest and most masterly exhibition is to be met with of the superior authority as witnesses for the truth of Revelation of the Scriptural as compared with the ex-Scriptural writers, and of the Christian as compared with the heathen testimonies. In his *Institutes of Theology*,

no material modification is either made or attempted on the doctrines of Calvinism, which he received with all simplicity of faith, as he believed them to be revealed in the Divine word, and which he defended as in harmony with the most profound philosophy of human nature and of the Divine providence.

The character of Dr Chalmers's intellect was eminently practical. The dearest object of his earthly existence was the elevation of the common people. Poor-laws appeared to him as calculated to retard this elevation; he therefore strenuously resisted their introduction. The Church of Scotland appeared to him as peculiarly fitted to advance it; he spoke, he wrote, he laboured in its defence and extension. "I have no veneration," he said to the royal commissioners in St Andrews, before either the Voluntary or the Non-intrusion controversies had arisen, "I have no veneration for the Church of Scotland *quasi* an establishment, but I have the utmost veneration for it *quasi* an instrument of Christian good." Forcing that church to intrude unacceptable ministers, and placing her in spiritual subjection to the civil power, in his regard stripped her as such an instrument of her strength, and he resolutely but reluctantly gave her up.

It is as a mover of his fellow men, as the reviver of evangelistic feeling in Scotland, and as a leader in the great movement which terminated in the erection of the Free Church, that Dr Chalmers will fill the largest place in the eye of posterity, and occupy a niche in the history of Scotland and of the church. Various elements combined to clothe him with public influence—a childlike, guileless, transparent simplicity, the utter absence of everything factitious in matter or manner—a kindliness of nature that made him flexible to every human sympathy—a chivalry of sentiment that raised him above all the petty jealousies of public life—a firmness of purpose that made vacillation almost a thing impossible, a force of will and general momentum that bore all that was movable before it—a vehement utterance and overwhelming eloquence that gave him the command of the multitude, a scientific reputation that won for him the respect and attention of the more educated—the legislative faculty that framed measures upon the broadest principles, the practical sagacity that adapted them to the ends they were intended to realize—the genius that in new and difficult circumstances could devise, coupled with the love of calculation, the capacity for business details, and the administrative talent that fitted him to execute—a purity of motive that put him above all suspicion of selfishness, and a piety unobtrusive but most profound, simple yet intensely ardent.

(W. H. A.)

CHALONER, SIR THOMAS (1515–1565), a statesman and poet, of a noble Welsh family, was born in 1515. Under Henry VIII. he was sent as ambassador to Charles V., whom he accompanied on his unfortunate expedition against Algiers in 1541. On his return he was appointed to the office of first clerk of the council. He gained the friendship of the duke of Somerset; but after his fall he was obliged to live in retirement, and during the reign of Mary his Protestantism still kept him from the court. On the accession of Elizabeth he was received into high favour, and appointed ambassador, first to the Emperor Ferdinand I., and then to the court of Spain, where, however, he found himself so uncomfortable that after three years' stay he obtained permission to return home in 1564. He died the following year. Chaloncr enjoyed considerable reputation as a poet, and left *Poetical Works*, *De Republica Anglorum Instauranda*, *the Praise of Folie* (from the Latin of Erasmus), *In Laudem Henrici Octavi Carmen Panegyricum*, *the Office of Servants* (from the Latin of Cognatus), and some other small pieces.

CHÂLON-SUR-SAONE, a town of France, capital of an arrondissement in the department of Saône-et-Loire, 81 miles by rail north of Lyons. It is a neat and well-built town, situated in an extensive plain on the right bank of the Saône, at the junction of the Canal du Centre, and connected by a fine stone bridge with the suburb of St Laurent on an island in the river. Its principal buildings are the cathedral of St Vincent, a Gothic edifice of the latter part of the 14th century, on the site of a church founded about 532; the church of St Pierre, with two lofty steeples; the hospitals of St Laurent and St Louis; the town hall, the market, and the courthouse. An obelisk was erected in the 18th century to commemorate the opening of the canal. There are tribunals of primary instance and commerce, an exchange, a communal college, a school

of design, a public library, and societies for agriculture, archaeology, and arts. The industrial establishments are extensive and various, comprising docks, flour-mills, sugar factories of the greatest importance. There is tile-works; and from the town the *essence d'orient*, a south of France, is scales of the bleak (*Cyprinus*) also manufactured in the fabrication of mock pearls.

Châlon-sur-Saône is identified by being frequently sacked. The town, originally a town of the Aduis. It was chosen in the 6th century by Gontram, king of Burgundy, as his capital; and it continued till the 10th to pay for its importance by service the town rendered in bishop, first appointed in the 4th century, by keeping in check a count in the 12th, and retained it to the 18th century, 20,055.

Châlon-sur-Saône is identified by being frequently sacked. The town, originally a town of the Aduis. It was chosen in the 6th century by Gontram, king of Burgundy, as his capital; and it continued till the 10th to pay for its importance by service the town rendered in bishop, first appointed in the 4th century, by keeping in check a count in the 12th, and retained it to the 18th century, 20,055.

CHÂLONS-SUR-MARNE, a town of France, capital of the department of Marne, is situated on the right bank of the river, here crossed by a fine stone bridge, 107 miles E. of Paris on the railway to Troyes for its population, Rheims by another line, in 48° 57' 21" N. lat. and 4° 21' 27" E. long. It occupies a considerable area, and is rather irregularly laid out; many of its streets are broad, and it has fine public walks. Among its principal buildings may be mentioned the cathedral of St Etienne, originally founded in the 12th century, the 12th, 13th, 14th, and 15th centuries; the town-hall, erected in 1771; the prefecture, formerly the count of Artois; the barracks of St Pierre, the Benedictine abbey; the public library, industrial school. The town is the seat of a number of societies of tribunals of primary instance and communal college, two theological seminaries, a theatre, a museum, a botanical garden, and agriculture, commerce, arts, and sciences. To the east of the town lies a large public park of 19 acres, the Jard, which was stripped of its trees during the French Revolution, 1870–1; and beyond the river is the church of Prudentienne, annually in the month of May the town is visited by of about 50,000 pilgrims. Châlons has long been an important industrial centre. As early as the 14th century it was famous for its woollen cloth, which was the name of the town, afterwards corrupted into "shiraz" and in the 18th it maintained an extensive manufacture of linen goods of various kinds. Besides these industries, it now carries on tanning and shoemaking, and the manufacture of cotton cloth and hosiery, while at the same time it is one of the principal seats of the champagne wine trade. The annual export amounts on an average to 1,000,000 bottles, and the cellars of Jacquesson et Fils have storage room for 3,000,000. About six miles east of the town is the beautiful church of Notre Dame de l'Epine, which was built in the 12th century, and restored in 1860. Population in 1872, 16,400.

Châlons-sur-Marne occupies the site of the chief town of the Catalauni, which became signalized by the defeat of Attila in the terrible conflict of 451. In 643 it was laid waste by Herbert of Vermandois; in 931 by Ralph of Burgundy, and in 947 by Robert of Vermandois; but in the four following centuries it attained great prosperity as a kind of independent state under the supremacy of its bishops, who held a most influential position in the kingdom, and obtained the title of grand-vassals of the crown. In 1214 the men of Châlons appeared in the first rank in the battle of Bouvines; and in the 15th century their descendants maintained their honour by twice (in 1430 and 1434) repulsing the English from their walls. In the 16th century the town sided with Henry IV., who in 1589 transferred thither the parliament of Paris, which shortly afterwards was bold enough to burn the bulls of Gregory XIV. and Clement VIII. In 1814 the Prussians took possession of the town.

after the expulsion of Maedonald, and in 1815 it was captured by Chernicheff. In 1856 Napoleon established a large camp, known as the Camp of Châlons, about 16 miles north of the town by the railway to Rheims. It was situated in the immediate neighbourhood of Grand Mourmelon and Petit Mourmelon, and occupied an area of 12,000 hectares or 29,650 acres. The troops were principally accommodated in tents, but also partly in wooden barracks. At the outbreak of the Franco-German war, the camp was occupied by the sixth army corps, under Canrobert, and it was afterwards held by MacMahon. On 22d August 1870, the town of Châlons was occupied by the Prussians, and in the course of the war it formed an important point of communication.

CHALOTAIS. See LA CHALOTAIS.

CHALYBÄUS, HEINRICH MORITZ (1796–1862), a distinguished German writer on philosophy, was born on the 3d July 1796. The facts of his life are few and unimportant. For some years after completing his university education he acted as lecturer in the Kreuz-Schule at Dresden, and while there his lectures on the history of philosophy in Germany, delivered before large audiences, drew attention to his rare merits as a thinker and writer. In 1839 he was called to a Professorship in Kiel University, where, with the exception of one brief interval, he remained till his death on 2d September 1862. His first published work, *Historische Entwicklung der spekulativen Philosophie von Kant bis Hegel*, 1837, was extremely popular, and still retains its place as one of the best and most attractive expositions of modern German thought. It has been twice translated into English, by Tulkin in 1854, and by Edersheim in 1860. His other writings are *Phänomenologische Blätter*, 1841; *Die moderne Sophistik*, 1843; *Entwurf eines Systems der Wissenschaftslehre*, 1846; *System der spekulativen Ethik*, 2 vols., 1850; *Philosophie und Christenthum*, 1853; *Fundamental-Philosophie*, 1861. Of these the most important are the *Wissenschaftslehre* and the *Ethik*. Chalybäus's general principle may be named Ideal-Realism. He opposes both the extreme realism of Herbart and what he calls the one-sided idealism of Hegel, and endeavours to find a mean between them, to discover the ideal or formal principle which unfolds itself in the real or material world presented to it. His *Wissenschaftslehre*, accordingly, divides itself into three parts,—*Prinziplehre*, or theory of the one principle; *Vermittelungslehre*, or theory of the means by which this principle realizes itself; and *Teleologie*. The most noticeable point is the position assigned by Chalybäus to the "World Ether," which is defined as the infinite in time and space, and which, he thinks, must be posited as necessarily coexisting with the Infinite Spirit or God. The *System der Ethik* is perhaps the richest and most thorough-going modern work on moral philosophy. The fundamental principle is carried out with great strength of thought, and with an unusually complete command of ethical material. A brief but satisfactory account of Chalybäus will be found in Erdmann, *Grundriss der Geschichte der Philosophie*, ii. 781–786.

CHÁMBÁ, a feudatory state of Northern India, subordinate to the Punjab Government, situated between 32° 10' and 33° 9' N. lat., and between 75° 54' and 76° 30' E. long. Chámbá is bounded on the N. by a range of mountains, separating it from the province of Zaskár in Kashmír; on the E. by the outlying British *pargánas* of Bangáhal and Lahaul, belonging to Kángra district; on the S. by mountain ranges which separate it from the Kángra valley; and on the W. by the provinces of Jammu and Kistwar in Kashmír. In shape the state is an oblong, its eastern and western sides being about 65 miles in length, and its mean width about 50 miles. It is traversed from east to west by a lofty range which divides it into two distinct valleys. The northern of these valleys is drained by the Chináb, which, rising in Lahaul, passes through Chámbá into Kashmír territory, having a general direction from south-east to north-west. The southern

valley is drained by the Rávi, of which one head is in Chámbá territory, and the other in Bangáhal. The two branches unite a short distance below Barnur in Chámbá. The river then flows eastwards till close to Dalhousie it turns southwards, and after forming the boundary of the state for some distance, enters the plains of the Punjab. The estimated population of the state is 140,000 souls, and the estimated gross revenue, £18,937. The annual tribute payable to the British Government is £500. Owing to the abdication of the late rájá and the succession of his son, a lad of seven years of age, the administration of the state passed under the direct control of the British Government in 1872–73, an arrangement which will continue during the minority of the young chief. The only towns in the state are Chámbá and Barnur situated on the Rávi, and Kílár on the Chináb. The British sanitarium of Dalhousie is within the limits of the state, situated upon ground purchased from the chiefs. The principal agricultural products are wheat and millet; among the other products are timber, wax, nuts, honey, lime, and slate from quarries near Dalhousie. The extensive forests are leased by the British Government, and are under the management of the Punjab Forest Department.

CHAMBERLAIN (Latin *camerarius*, from *camera*, a chamber; French *chambellan*), etymologically, and also historically to a large extent, an officer who superintends the arrangement of domestic affairs. Such were the chamberlains of monasteries, and the chamberlains of cathedrals, who had charge of the finances, gave notice of chapter meetings, and provided the materials required for various services. A royal chamberlain is an officer whose function is in general to attend on the person of the sovereign, and regulate the etiquette of the palace. The Roman emperors appointed this officer under the title of *cubicularius*. During the Middle Ages, the royal chamberlain usually enjoyed the important privilege of keeping the king's signet ring; and it seems that the mayoralty of the palace, which gradually acquired such an authority as to overthrow the Merovingian dynasty in France, grew out of an office corresponding to that of the chamberlain. The chamberlain of the Pope enjoys very extensive powers, having the revenues of the church under his charge. In France, the office existed from very early times till the reign of Louis XIV., and was revived by Napoleon.

The Lord Great Chamberlain of England originally took rank after the Lord Privy Seal. The office is hereditary, and belonged at one time to the De Veres, from whom it descended by the female line into the family of Bertie. On the death of the fourth duke of Ancaster in 1777, it passed to the houses of Cholmondeley and Willoughby d'Eresby. From these families alternately a Lord Great Chamberlain is appointed on the death of the reigning monarch. The principal duties of this office are to take charge of the houses of parliament, and to attend on the sovereign at his coronation.

The Lord Chamberlain is an officer distinct from the Lord Great Chamberlain, and of greater importance, though his functions are less responsible than they were formerly. He is regarded as chief officer of the royal household; he has charge of a large number of appointments, such as those of the royal physicians, tradesmen, and private attendants of the sovereign; he is licenser of plays; and he examines the claims of those who desire to be presented at court. He is a member of the privy council, and holds office during the ascendancy of the political party to which he belongs.

Many corporations appoint a chamberlain. The most important in England is the chamberlain of the corporation of the city of London, who is treasurer of the corporation, admits persons entitled to the freedom of the city

and determines disputes between masters and apprentices. He is elected annually by the liverymen.

CHAMBERS, EPHRAIM, an English author, was born at Kendal, Westmoreland, in the latter part of the 17th century. He was apprenticed to a globe-maker, but having conceived the plan of his *Cyclopædia*, he left this business, and devoted himself entirely to writing. The first edition of the *Cyclopædia*, which was the result of many years' intense application, appeared by subscription in 1728, in two vols. fol. It was dedicated to the king, and procured for Mr Chambers the honour of being elected fellow of the Royal Society. In less than ten years a second edition was printed, with corrections and additions (in 1738); and this was followed by a third a year later. In addition to the *Cyclopædia*, Mr Chambers wrote for the *Literary Magazine*, and translated the *History and Memoirs of the Royal Academy of Sciences at Paris* (1742), and the *Jesuits' Perspective*. He died in 1740.

CHAMBERS, GEORGE (1803–1840), a marine painter, born at Whitby, Yorkshire, was the son of a seaman, and for several years he pursued his father's calling. While at sea he was in the habit of sketching the different classes of vessels. His master, observing this, gratified him by cancelling his indentures, and thus set him free to follow his natural bent. Chambers then apprenticed himself to an old woman who kept a painter's shop in Whitby, and began by house-painting. He also took lessons of a drawing-master, and found a ready sale for small and cheap pictures of shipping. Coming afterwards to London, he was employed by Thomas Horner to assist in painting the great panorama of London for the Colosseum (the exhibition building in the Regent's Park, recently demolished), and he next became scene-painter at the Pavilion Theatre. In 1834 he was elected an associate, and in 1836 a full member, of the Water-colour Society. His best works represent naval battles. Two of these—the Bombardment of Algiers in 1836, and the Capture of Porto Bello—are in Greenwich Hospital. Not long before his death he was introduced to William IV., and his professional prospects brightened; but his constitution, always frail, gave way, and brought him to an early grave. He died on the 28th October 1840. A Life of him, by John Watkins, was published in 1841.

CHAMBERS, ROBERT (1802–1871), author and publisher, distinguished especially for his services to popular literature, was born at Peebles on the 10th July 1802. His parents were of the middle class, but owing to the father's misfortunes in business the family were reduced to poverty, and had to leave Peebles for Edinburgh while Robert was still young. He had before that received such an education as the parish and grammar schools of his native place afforded, and had shown himself possessed of unusual literary taste and ability. A small circulating library in the town, and a copy of the first edition of the *Encyclopædia Britannica* which his father had purchased, furnished him with stores of reading of which he eagerly availed himself. Long afterwards he wrote of his early years—"Books, not playthings, filled my hands in childhood. At twelve I was deep, not only in poetry and fiction, but in encyclopædias."

In Edinburgh the family had a somewhat hard struggle with their straitened circumstances. Robert had been destined by a sort of tacit understanding for the church, and was placed for a time at a classical school with a view to his being sent to the university. This design had, however, to be abandoned. After enduring many hardships, and making two unsuccessful attempts to fill situations in mercantile houses in Leith, he commenced business on his own account as a bookstall-keeper in Leith Walk, on the advice of his elder brother and future partner,

William. He was then only sixteen, and his whole stock consisted of a few old books belonging to his father. By slow degrees the stock was increased and the business extended. A similar but distinct concern was carried on during the same period with like success by William, and after a number of years the two brothers were united as partners in the now well-known publishing firm of W. and R. Chambers.

From the commencement of his residence in Edinburgh, Robert Chambers had shown an enthusiastic interest in the history and antiquities of the city. In frequent rambles every feature of its ancient buildings grew familiar to him, and his mind became a storehouse for all sorts of information connected with its famous persons and places. He thus found a most congenial task in the publication of the *Traditions of Edinburgh* (1823–4), which, though not his first work, was the first which brought him into general notice. It secured for him the approval, and what he doubtless valued even more highly, the personal friendship of Sir Walter Scott, then in the zenith of his fame. Other works on kindred subjects followed in rapid succession, the most popular and important being a *History of the Rebellion of 1745*. He also wrote from time to time a number of short poetical pieces of very considerable merit, which were afterwards collected and printed for private circulation (1835). For a year or two he acted as editor of the *Edinburgh Advertiser*, a Tory newspaper of old standing, which has now ceased to appear. With commendable and characteristic prudence the bookselling business was diligently prosecuted in the midst of these numerous literary engagements, so that his life at this period was one of ceaseless activity.

In the beginning of 1832 his brother William, after consultation with him, started a weekly publication under the title of *Chambers's Journal*, which speedily attained an immense circulation, and still holds a leading place in the cheap popular periodical literature of which it was the pioneer. Robert's connection with it was at first only that of a contributor. After fourteen numbers had appeared, however, he became associated with his brother as joint-editor, and from that period he wrote for it nearly all the leading articles, which took the form of essays—moral, familiar, and humorous. Written in an easy, graceful style, entirely free from any affectation of condescension, always interesting, and carefully avoiding the debateable ground of religion and politics, they contributed more perhaps than anything else to the remarkable success of the *Journal*. A number of them were republished in 1847 in the author's *Select Writings*, and are thought to be on the whole the best specimens of his original work. Of the same character as his work for the *Journal* were his numerous contributions to the *Information for the People* and the *Miscellany of Useful and Entertaining Tracts* published by his firm.

Among the other works of which he was in whole or in part the author, the *Cyclopædia of English Literature*, the *Life and Writings of Burns*, *Ancient Sea Margins*, the *Domestic Annals of Scotland*, and the *Book of Days* were the most important. The *Cyclopædia of English Literature* contained a series of admirably selected extracts from the best authors of every period, "set in a biographical and critical history of the literature itself." The biographies were gracefully written, and the critical estimates, though brief, were just and comprehensive. For the *Life of Burns* he made diligent and laborious original investigations, gathering many hitherto unrecorded facts from the surviving acquaintances of the poet, and especially from his sister, Mrs Begg, to whose benefit the whole profits of the work were generously devoted. The poems are interwoven into the narrative in their proper chronological order, and

with all the information that could be obtained as to the circumstances of their composition. In connection with the work on *Ancient Sea Margins*, it may be mentioned that its author ranked high as a scientific geologist, and that he had availed himself of tours in Scandinavia and Canada for the purpose of geological exploration. His knowledge of geology was one of the principal grounds on which the authorship of the celebrated anonymous work, *The Vestiges of the Creation*, was very generally attributed to him. As, however, neither he himself nor any one entitled to speak for him ever acknowledged the work, its authorship remains a mystery. The *Book of Days* was his last publication, and perhaps his most elaborate. Help on which he had depended having failed him, he was left to do the work almost alone, and it is supposed that his excessive labour in connection with it hastened his end. He died at St Andrews, where he had built a pleasant residence for himself several years previously, on the 17th March 1871. Two years before his death the university of St Andrews had conferred upon him the degree of Doctor of Laws, in consideration of his distinguished literary merit, and he was a fellow of several learned societies. As a writer Chambers possessed in very harmonious combination most of the qualities which form the basis of a sound and lasting popularity. Few even of popular authors ever possessed in a higher degree the faculty of interesting without resorting to sensation, of amusing without stooping to frivolity, and of instructing without assuming superiority. Few have done more than he for the illustration of Scottish life and character, and for the preservation of what was curious in Scottish tradition and antiquities. But it will always be his highest claim to distinction that he did as much as, if not more than, any other single man to give a healthy tone and a pure moral influence to the cheap popular literature which has become so important a factor in modern civilization. An interesting account of the life of Robert Chambers by his brother appeared in 1872, under the title, *Memoir of Robert Chambers: With Autobiographic Reminiscences of William Chambers*. (W. B. S.)

CHAMBERSBURG, a town of the United States, the capital of Franklin county, Pennsylvania, is situated about 135 miles west of Philadelphia, in a populous district in the great limestone valley that extends along the east side of the Blue Mountains. It has a court-house, a national bank, ten churches, and a Presbyterian college for young ladies; and it manufactures cotton, wool, paper, and iron. In 1864 a large part of the town was burned by the Confederates under Early. Population in 1870, 6308.

CHAMBERY (in Italian CIAMBERT), a city of France, capital of the department of Savoy, pleasantly situated in a fertile district, between two hills, on the rivers Laisse and Albana, 46 miles S.S.W. of Geneva. The town, however, is irregularly and ill built, and has only two good streets—the Place Saint-Léger and the Rue de Boigne, of which the latter is named after a General Boigne who left a fortune of 3,400,000 francs to the town. The principal edifices are the cathedral, dating from the 14th and 15th centuries; the Hotel-Dieu, founded in 1647; the castle, a modern building serving as a prefecture, and preserving only a great square tower belonging to the original structure; the palace of justice, the theatre, the barracks, and the covered market, which dates from 1863. Several of the squares are adorned with fountains; the old ramparts of the city, destroyed during the French Revolution, have been converted into public walks; and various promenades and gardens have been constructed. Chambery is the seat of an archbishop, and of a superior tribunal; and has also a Jesuit college, a royal academical society, a society of agriculture and commerce, a public library, with 20,000 vols., a museum, a botanic garden, and many charitable

institutions. It manufactures silk-gauze, lace, leather, and hats, and has a considerable trade in liqueurs, wine, lead, copper, and other articles. Overlooking the town is the Rock of Lemenc, which derives its name from the *Lemincum* of the Romans; and in the vicinity is Charmettes, for some time the residence of Rousseau.

The origin of Chambery is unknown, but its lords are mentioned for the first time in 1029. In 1232 it was sold to the count of Savoy, Thomas I., who bestowed several important privileges on the inhabitants. As capital of the duchy of Savoy, it has passed through numerous political vicissitudes. From the middle of the 16th century to 1713 it was in the hands of the French; in 1742 it was captured by a Franco-Spanish army; and in 1792 it was occupied by the Republican forces. Restored to the house of Savoy by the treaties of Vienna and Paris, it was again surrendered to France in 1860. Among the famous men whom it has given to France, the most important are Vaugelas, Saint-Réal, and the brothers Joseph and Xavier de Maistre. Population of the town in 1872, 17,331, and of the commune, 19,144.

CHAMBORD, a magnificent Gothic château of France, in the department of Loire-et-Cher, 10 miles east of Blois, on the left bank of the Cosson. It was commenced by Francis I. in 1532, carried on by Henry II., and at length finished by Louis XIV. It is built of black stone, with a profusion of towers, turrets, and minarets, and the interior is fitted up with great magnificence. The park is enclosed by walls seven leagues in circumference. The castle is famous as the residence of Diana of Poitiers, and of Stanislaus, king of Poland, whose son-in-law, Louis XV., bestowed it upon Marshal Saxe. It was given by Napoleon to Marshal Berthier, from whose widow it was purchased by subscription in 1821, and presented to the duke of Bordeaux, the representative of the older branch of the Bourbons, who has assumed from it the title of Count de Chambord.

CHAMELEON, the common name of a well-defined family of Lizards, forming the tribe *Dendrosauræ*, and containing the single genus *Chamælo*, which includes about twenty known species, bearing a close family resemblance to each other, and differing very widely from all other lizards. They are small creatures, not usually exceeding 7 inches in length exclusive of the tail, which in general is as long as the body. The body is greatly compressed, often with a crest—toothed or otherwise—along the back and belly, and the skin is covered with granular specks, giving it the appearance of shagreen. The large pyramidal head is supported by a short neck composed of five vertebrae, instead of eight, as in the majority of saurians; and there is no true sternum, although the anterior ribs are joined to the mesial line, which thus takes the place of a breast-bone, while the ribs which follow are so connected together as to form a bony circle for the protection of the abdominal region. Unlike other lizards, the chameleon has the body raised high on its legs, and the toes, which are five in number on both posterior and anterior limbs, are divided into two opposable groups or bundles, closely resembling those of a parrot, and equally serving the purpose of prehension. The tail, by the greater thickness of which at the base the male is distinguishable from the female, is also prehensile, and is of the greatest service in giving support and security to the climbing chameleon. The lungs are large, and are connected with air-vessels distributed throughout the body, by the inflation of which a certain transparency is given to the body, as well as a plumpness which at once disappears on their collapse, and this, together with the fact that the chameleon can live apparently in a thriving condition for weeks without food, seems to have given rise to the ancient belief that this singular creature lived on air. The eyes of the chameleou are large, globular, and covered with a circular disk formed by the junction of the two lids and having a central aperture which acts as an external pupil, being capable of dilatation or contraction

at will. In moving, the eyes act independently of each other, so that while the one stares upwards the other may be eagerly following the motions of an insect beneath, or the one may even be directed backwards while the other watches in front. This extraordinary range of vision amply compensates for the small degree of mobility in the neck and the general slowness of motion characteristic of the chameleon. The tongue is equally remarkable, being sub-cylindrical, worm-like, and extremely extensible, with the end somewhat enlarged and hollow, and supplied with a glutinous secretion. It is by means of this organ, which is capable of being protruded to a length of six or seven inches, that chameleons obtain their food. They are arboreal in their habits, supporting themselves on the branches of trees by their grasping hand-like feet and prehensile tails. In their movements they are slow and deliberate, and when watching for the insects which form their sole food, they remain motionless for hours, partly concealed by the foliage, and still more by the exercise of the faculty which they possess above all other creatures of changing their colour so as to resemble surrounding objects. Their power in this direction has, however, been greatly exaggerated. They cannot, as was at one time supposed, assume in succession all the colours of the rainbow; but under certain conditions, by no means well ascertained, their normal bluish ash colour may give place to a green or yellowish hue, with irregular spots of a dull red, or it may become considerably paler so as to approach to whiteness. Thus an observer reports recently that he saw a chameleon making its way along the top of an old wall near Ephesus, the stones of which were of a dark colour, occasionally varied by a block of white marble, and he noticed that no sooner did the creature rest on one of the latter than it gradually became less visible, owing evidently to its assumption of a colour somewhat harmonizing with the marble on which it rested. This curious phenomenon was observed by the earliest writers on natural history, and gave rise to much speculation. Aristotle held that the change of colour only took place when the chameleon was inflated with air, to which therefore it was owing; Pliny that its varying colours were borrowed from surrounding objects; while Wormius was the first to attribute those variations to the play of the emotions and passions; but Milne Edwards, in a paper published in the *Annales des Sciences*, showed that, whatever the exciting cause of these changes in colour, whether due to the emotions, the inflation of the lungs, or exposure to the sun's rays, they were rendered possible only by the presence in the skin of the chameleon of two layers of differently-coloured pigment, placed one over the other, and so arranged that both may appear simultaneously on the surface, or the one may be displaced to a greater or less extent by the other, the colour varying with the amount of such displacement. Thus protected by its colouring, the chameleon awaits the coming of its prey, and no sooner does an insect place itself within reach of its worm-like tongue than that organ, leaping forth from its sheath with lightning speed, fixes its victim on the glutinous tip, which is forthwith engulfed with equally astonishing rapidity. The eggs of the chameleon are deposited under leaves on the ground. They are numerous, round, and covered with an exceedingly porous shell formed of calcareous matter. The species composing the family are inhabitants chiefly of Africa and the islands adjacent, notably of Madagascar, to which about a third of all the known species are confined. The latter include such curious forms as the Rhinoceros Chameleon, the male of which has a horn-like tubercle at the end of the muzzle; also a form recently described by Günther, in which the tail is so short as to be almost useless for prehension, a defect which seems compensated for by the presence of an

additional denticle at the inner base of each claw, and of a spine projecting from the side of each finger and toe, which must add greatly to the creature's prehensile power. Owing to this peculiarity Günther proposes to make it the type of a new genus (*Proceedings of the Zoological Society*, 1874). Fernando Po is the home of the Three-Horned Chameleon (*Chamaleo Oweni*), which has a long conical horn over each eye, and another at the extremity of the muzzle; but the best known and most widely distributed species is the Common Chameleon (*C. vulgaris*), found in Southern Asia and the north of Africa, and naturalized in the southern countries of Europe. It is often brought to England, but owing to the coldness of the climate it exists there in a more or less torpid condition, and soon dies.

CHAMFORT, NICOLAS (1741-1794), one of the most famous talkers of a century rich in conversational excellence, was born at a little village near Clermont in Auvergne. The illegitimate child of a *dame de compagnie*, he never knew his father, and started in life as plain Nicolas, that being the name bestowed on him by his mother. A journey to Paris resulted, through some now unknown influence, in the boy's obtaining a bursary at the Collège des Grassins. He worked hard, and won nine prizes out of ten in two years. It is significant of his cynical and original turn of mind that he should have been the only critic disposed to be severe on the Latin hexameters that crowned his college reputation, and that in after years he should have regarded as wasted the time bestowed on the acquisition of academical knowledge, his opinion of which is expressed in one of his most contemptuous epigrams—"Ce que j'ai appris je ne le sais plus; le peu que je sais je l'ai diviné." After this success the future king of the salons ran away from college, in company with two class-mates, on a voyage round the world. The three rovers reached Cherbourg, and there reflected. They returned, and Chamfort became an abbé. "*C'est un costume, et non point un état*," he said; and to the principal of his college who promised him a benefice, he replied that he would never be a priest, inasmuch as he preferred honour to honours—"j'aime l'honneur et non les honneurs."

About this time he assumed that name of Chamfort he was afterwards to render famous, and plunged hap-hazard into the press for literary work and renown. He met with scant success. Repulsed by editors and booksellers alike, he took to making sermons at a louis each for an incompetent brother; and in this way, scribbling now and then for the journals, he contrived to exist for a whole year. A successful competition for one of the Academy's prizes opened to him the drawing-rooms of the upperworld, and he became fashionable. His health and constitution were exceedingly vigorous; but his passions were violent, he lived hard, and he presently had to seek rest and recovery at Spa and elsewhere. In a second competition he was unsuccessful; but a comedy of little merit, *La Jeune Indienne*, made some noise, and consoled him for his failure. He was always poor. Though his was already a well known name, he lived on eleemosynary dinners and suppers, repaying countenance and sustenance with his *bons mots*. Madame Helvétius entertained him at Sèvres for some years. Chabanon, however, gave up to the destitute wit his pension of 1200 livres on the *Mercur de France*, and about the same time Chamfort took two more Academy prizes for his eulogies on Molière and on La Fontaine, by which he also won a hundred louis from Necker, and obtained an enormous reputation. And as he wrote little and talked a great deal, his reputation increased, till, under protection of the Duchesse de Grammont, he went to court. His poor tragedy, *Mustapha et Zangir*, was played at Fontainebleau before Louis XVI. and Marie Antoinette; the king added 1200 livres to the gift of Chabanon, and the Prince de Condé made Chamfort his

secretary. The man was then some forty years of age; he was fast growing misanthropical; he was "*gai mais ombrageux*;" he was a Bohemian naturally and by habit. He resigned his post in the prince's household, and retired into solitude at Auteuil. There, comparing the authors of old with the men of his own time, he uttered the famous *mot* that proclaims the superiority of the dead over the living as companions; and there too he presently fell in love. The lady, attached to the household of the Duchesse de Maine, was forty-eight years old, but clever, amusing, a woman of the world; and Chamfort married her. They left Auteuil, and went to Vaudouleurs, near Etampes, where in six months Madame Chamfort died. The widowed epicurean travelled, lived in Holland for a space with M. de Narbonne, and returning to Paris received the Academy arm-chair left vacant by the death of Sainte-Pelaye in 1781. He haunted the court, and made himself loved in spite of the reach and tendency of his unalterable irony; but he quitted it for ever after an unfortunate and mysterious love affair, and was received into the house of M. de Vaudreuil. Among the many men of mark assembled round him there by his fine faculty of pregnant speech, he made the acquaintance and gained the friendship of Mirabeau, whom he assisted with orations, and whom he followed heart and soul into the storm and tumult of the young Revolution.

He forgot his old friends ("*ceux qui passent la fleuve des révolutions ont passé la fleuve de l'oubli*"); he frequented the clubs, and for a time was secretary of that of the Jacobins; he became a street-orator; he entered the Bastille among the first of the storming party; he worked for the *Mercur de France*, a royalist print in which he depreciated kingship. With the reign of Marat and Robespierre, however, his uncompromising Jacobinism grew critical, and with the fall of the Girondins his political life came to an end. But he could not restrain the tongue that had made him famous; he no more spared the Convention than he had spared the Court. His notorious republicanism failed to excuse the sarcasms he lavished on the new order of things; and denounced by an assistant in the *Bibliothèque Nationale*, to a share in the direction of which he had been appointed by Roland, he was taken to the Madelonnettes. Released for a moment, he was threatened again with arrest; but to this brilliant free-lance of thought captivity had been intolerable, and he had determined to prefer death to a repetition of the moral and physical restraint to which he had been subjected. He attempted suicide, with pistol and with poniard; and, horribly hacked and shattered, dictated to those who came to arrest him the well-known declaration—"*Moi, Sébastien-Roch-Nicolas Chamfort, declare avoir voulu mourir en homme libre plutôt que d'être conduit en esclave dans une prison*"—which he signed in a firm hand and in his own blood. He did not die at once, but lingered on a while in charge of a gendarme, for whose wardship he paid a crown a day. To the Abbé Sieyès Chamfort had given fortune in the title of a pamphlet ("*Qu'est-ce que le Tiers-État? Tout. Qu'a-t-il? Rien*"), and to Sieyès did Chamfort retail his supreme sarcasm, the famous "*Je m'en vais enfin de ce monde où il faut que le cœur se brise ou se bronze*." The maker of constitutions followed the dead wit to the grave.

The writings of Chamfort, which include comedies, political articles, literary criticisms, portraits, letters, and verses, are colourless and uninteresting in the extreme. As a talker, however, he was of extraordinary force. His *Maximes et Pensées*, highly praised by John Stuart Mill, are, after those of La Rochefoucauld, the most brilliant and suggestive sayings that have been given to the modern world. The aphorisms of Chamfort, less systematic and psychologically less important than those of the ducal moralist, are as significant in their violence and iconoclastic spirit of the

period of storm and preparation that gave them birth as the *Réflexions* in their exquisite restraint and elaborate subtlety are characteristic of the tranquil elegance of their epoch; and they have the advantage in richness of colour, in picturesqueness of phrase, in passion, in audacity. Sainte-Beuve compares them to "well-minted coins that retain their value," and to keen arrows that "*arrivent brusquement et sifflent encore*." An edition of his works—*Œuvres complètes de Nicolas Chamfort*, 5 volumes—was published at Paris in 1824–25. A selection—*Œuvres de Chamfort*—in one volume, appeared in 1852, with a biographical and critical preface by Arsène Houssaye, reprinted from the *Revue des Deux Mondes*. See also Sainte-Beuve, *Causeries de Lundi*. (W. E. H.)

CHAMISSO, ADALBERT VON (1781–1838), poet, botanist, and voyager, was by family, birth, and the education of childhood, a Frenchman, by his after-life, his marriage, and his literary activity, a German. He was born in 1781 at the castle of Boncourt in Champagne, and traced his descent from a respectable line of French knights, who derived their title from the ancient town of Chamesson or *Cambisonum*, near Châtillon-sur-Seine. The quiet home-life at Boncourt was broken up by the Revolution in 1790, and the Chamissos, parents and children, were forced, like so many of their rank, to leave their country, and find such footing as might chance in a foreign land. And though in after years the main part of the family was permitted to settle again on their native soil, several of the younger members were left behind, where they had begun to take root. Of these was Adalbert, who had in 1796 obtained a situation as page to the queen of Prussia, and in 1798 entered the military service with the rank of ensign. To his professional studies he devoted himself with ardour, and he attracted the royal attention by some of his writings; but in the society of his comrades he was made bitterly to feel that he was not regarded as one of themselves, and it was not altogether with regret that he found himself in 1806 set free from the army. Meanwhile he had formed a friendship with several congenial spirits, such as Hitzig, Varnhagen von Ense and Neumann; and with the last two he joined in the publication of the *Musenalmannach*, which first appeared in 1803. A visit to Madame de Stael at Coppet was a pleasing interruption to his ordinary course of life, and has afforded the reader of his letters some amusing description of that eccentric woman, who alternately flattered Chamisso for his ability and scolded him soundly for his inattention to etiquette. The study of botany, which he began at Coppet, was prosecuted with so much persistence and success that it became his professional subject. In 1815 he was chosen botanist of the expedition for the circumnavigation of the world, which was originated by Romanzoff, and conducted by Kotzebue; and on his return in 1818 he was appointed custodian of the botanical gardens at Berlin. Much to his own advantage and comfort, he obtained the hand of Antonie Piaste, a young lady of eighteen years; and the rest of his life was spent in steady professional labour, relieved by kindly intercourse with an increasing circle of friends. Among those with whom he became acquainted were August Neander, Freiligrath, and Andersen.

It cannot be said of Chamisso, as he himself affirmed of Heine, that he was a poet to the very tips of his fingers; but the poetic element in his nature was genuine and strong, and, in spite of the unfavourable circumstances of his life, his tendency towards literary expression was very early displayed. In estimating his success as a writer, it should not be forgotten that he was cut off from his native speech and from his natural current of thought and feeling. None of his works perhaps can be called great; but he has none the less enriched his adopted language with several poems

of undisputed and enduring value. He often deals with gloomy and sometimes with ghastly and repulsive subjects; and even in his lighter and gayer productions there is too frequently an undertone of sadness or of satire. In the lyrical expression of the domestic emotions he displays a fine felicity, and he knows how to pour true pathos into a tale of love or vengeance. The "*Lion's Bride*"—*Die Löwenbraut*—may be taken as a sample of his weird and powerful simplicity; and "*Retribution*,"—*Vergeltung*—is remarkable for a pitiless precision of treatment. The "*Song of Women's Devotion*"—*Ein Lied von der Weibertreue*—might find a place in the *Ingoldsby Legends*; and "*Cousin Anselmo*"—*Vetter Anselmo*—is worthy to rank with the ballads of Southey. Of more celebrity perhaps than any of his poems is the little prose narrative of *Peter Schlemihl*, the man who lost his shadow, which first appeared in 1814, and was soon afterwards translated into several European languages. It was written partly to divert his own attention from gloomier thoughts, and partly to afford amusement to the children of his friend Hitzig; and the plot was suggested by a casual question of Fouqué's. First and prominently a genuine story such as children love, with full allowance of incident and fun, it is also to the older and sympathetic reader an allegory only too accurate of the poet's own life. For full details see the *Leben und Briefe*, by Hitzig, in the fifth and sixth volumes of Chamisso's *Werke*.

Works.—*Uebersicht der nützlichsten und schädlichsten Gewächse in Norddeutschland*, 1827; *Reise um die Welt; Bemerkungen und Ansichten auf einer Entdeckungsreise unter Kotzebue*, 1827; *Ueber die Hawaische Sprache*, 1837.

CHAMOIS (*Rupicapra tragus*), the *Gemse* of the Germans, is the only Antelope found in Western Europe, and forms the type of the Rupicaprine or goat-like group of that family. It resembles the roebuck in size, being about 3 feet long and 2 feet high at the shoulders, and is specially characterized by the form of its horns. These are from 6 to 8 inches long, of a black colour, slender, round, and slightly striated, rising perpendicularly from the forehead, and suddenly hooked backwards at their extremities. They are common to both sexes, although in the female they are less uncinated. The body is covered with long hair of a chestnut brown colour in winter, when it is also longest, that of the head being paler, with a dark brown streak on each side. At other seasons the colour is somewhat lighter, in spring approaching to grey. Underneath the external covering the body is further protected from the cold by a coat of short thick wool of a greyish colour. The tail is short and black, the ears pointed and erect; the hoofs are solid, with the outer edges higher than the soles, and are thus admirably adapted for laying hold of the slightest projection or roughness on the face of the rocky precipices it frequents. The chamois is gregarious, living in herds of 15 or 20, and feeding generally in the morning or evening. The old males, however, live alone except in the rutting season, which occurs in October, when they join the herds, driving off the young males, and engaging in fierce contests with each other, that often end fatally for one at least of the combatants. The period of gestation is twenty weeks, when the female, beneath the shelter generally of a projecting rock, produces one and sometimes two young. They are said to attain the age of thirty years. The chamois inhabits the Alpine regions of Central Europe from the Pyrenees to the Caucasus, and extends eastwards as far as Persia, frequenting the wildest and most inaccessible peaks and ravines of these mountain ranges. In summer it ascends to the limits of perpetual snow, being only outstripped in the loftiness of its haunts by the ibex; and during that season it shows its intolerance of heat by choosing such browsing grounds as have a northern exposure. In

winter it descends to the wooded districts that immediately succeed the region of glaciers, and it is there only that it can be successfully hunted. Chamois are exceedingly shy; and their senses, especially those of sight and smell, are exceedingly acute. The herd never feeds without having a sentinel posted on some suitable prominence to give timely notice of the approach of danger; this is done by stamping on the ground with the fore feet, and uttering a shrill whistling note, which puts the entire herd on the alert. No sooner is the object of alarm scented or seen than each one seeks safety in the most inaccessible situations, which are often reached by a series of astounding leaps over crevasses, up the faces of seemingly perpendicular rocks, or down the sides of equally precipitous chasms. The chamois will not hesitate, it is said, thus to leap down 20 or even 30 feet, and this it effects with apparent ease by throwing itself forward diagonally and striking its feet several times in its descent against the face of the rock. Chamois-shooting is most successfully pursued when a number of hunters form a circle round a favourite feeding ground, which they gradually narrow; the animals, scenting the hunters to windward, fly in the opposite direction, only to encounter those coming from leeward. Chamois-hunting, in spite of, or perhaps owing to, the great danger attending it, has always been a favourite pursuit among the hardy mountaineers of Switzerland and Tyrol, as well as of the amateur sportsmen of all countries, with the result that the animal is now much rarer than formerly. In certain parts of Switzerland it now enjoys a close season; thus in the Canton of Grisons it can only be hunted during September, and there in 1874 no fewer than 918 were killed during that period, the largest number shot by one sportsman being 16. The chamois feeds in summer on mountain herbs and flowers, and in winter chiefly on the young shoots and buds of the fir and pine trees. It is particularly fond of salt, and in the Alps sandstone rocks containing a saline impregnation are often met with hollowed by the constant licking of these creatures. The skin of the chamois is very soft; made into leather it was the original *shammy*, which is now made, however, from the skins of many other animals. The flesh is prized as venison. The chamois can be at least partially tamed, and in that state, according to Major Smith, it evinces all the mixture of impudence, timidity, and curiosity observed in goats.

CHAMOMILE or CAMOMILE FLOWERS, the *flores anthemidis* of the *Pharmacopœia*, are the capitula or flower-heads of *Anthemis nobilis* (Nat. Ord. *Compositæ*), a plant indigenous to England and Southern Europe. It is extensively cultivated for medicinal purposes in Surrey, at several places in Saxony, and in France and Belgium,—that grown in England being much more valuable than any of the foreign chamomiles brought into the market. In the wild plant the florets of the ray are ligulate and white, and contain pistils only, those of the disc being tubular and yellow; but under cultivation the whole of the florets tend to become ligulate and white, in which state the flower-heads are said to be double. The flower-heads are destitute of pappus; they have a warm aromatic odour, which is characteristic of the entire plant, and a very bitter taste. In addition to a bitter extractive principle, they yield about 2 per cent. of a volatile liquid, which on its first extraction is of a pale blue colour, but becomes a yellowish brown on exposure to light. It has the characteristic odour of the flowers, and consists of a mixture of butylic and amylie angelate and valerate. Angelate of potassium has been obtained by treatment of the oil with caustic potash, and angelic acid may be isolated from this by treatment with dilute sulphuric acid. Chamomile is used in medicine in the form of an infusion, made

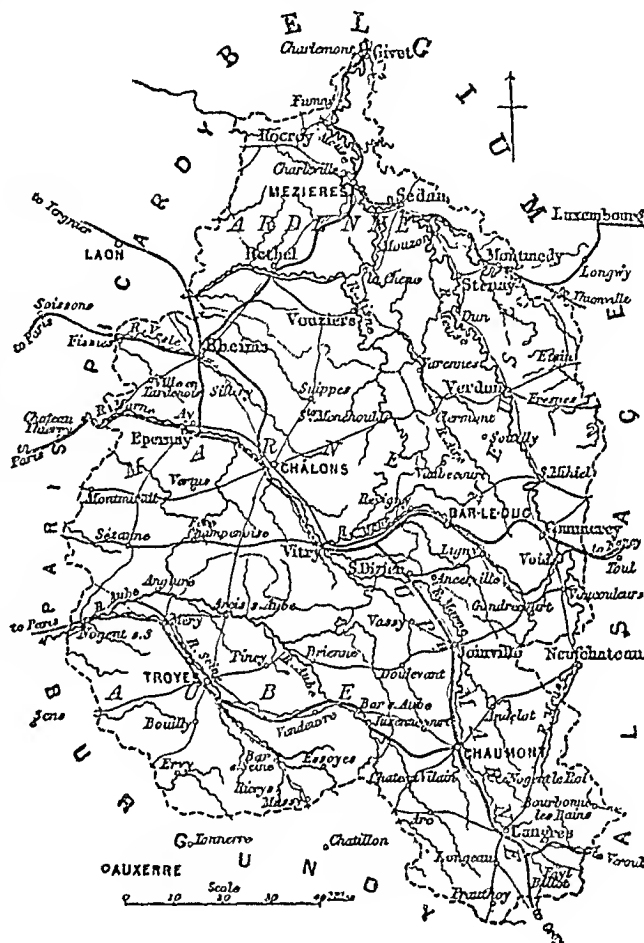

with $\frac{1}{2}$ oz. of the flowers to 10 oz. of boiling distilled water. An extract is also prepared by evaporating the infusion, and subsequently adding 15 minims of the essential oil for each pound of flowers used. It is an aromatic tonic and stomachic, and the infusion, if given warm and in large doses, acts as an emetic. The oil is stimulant and carminative, and forms a useful adjunct to purgative medicines.

CHAMOUNI, or CHAMONIX, a celebrated valley and village of the French Alps, in the department of Upper Savoy, and the arrondissement of Bonneville. The village, which is the great centre for tourists in the Mont Blanc district, is situated 22 miles S. of Martigny, and 50 miles E.S.E. of Geneva, at a height of about 3400 feet above the level of the sea. A great part of it was destroyed by fire in 1855, and it has thus undergone a striking change in its appearance. It now possesses numerous hotels, a museum, and baths; and an English chapel was opened in 1860. Upwards of 15,000 tourists are accommodated in the course of a year, the greater proportion being from England, America, and France. The busiest months are August and September. Excellent butter and cheese are prepared by the peasants, and flax and honey are exported. The valley, which is bounded on the S. and E. by Mont Blanc and others of the Pennine Alps, and on the W. and N. by Brévent and the Aiguilles Rouges, is about 12 miles in length from north-east to south-west, with an average breadth of two miles; it forms the upper part of the basin of the Arve, which traverses its entire length. It is the most celebrated in the Alps for the picturesque grandeur of its glaciers, which are only rivalled by those of the Zermatt in the Bernese Oberland. The view from the village up to the top of Mont Blanc is remarkable for its simple and massive sublimity.

The name of Chamouni is a corruption of the words *Campus Munitus*, or Champ Muni, the Defenced Field, applied by the Benedictine monks to the site of the monastery here, probably with allusion to the protection afforded by the "strength of the hills." This establishment was founded some time before 1099, on the spot that is now occupied by the village church; and it has left but little trace of its existence save the name of Le Prieuré, sometimes used instead of Chamouni. In 1530 the right of holding fairs at the priory was granted by Philip of Savoy, and the place thus became a rendezvous for the surrounding population. The reputation of the valley, however, for the savagery of its inhabitants was so great that the nickname of The Cursed Mountains—*Les Montagnes Maudites*—was given to the district; and in the 17th century it was regarded as a proof of remarkable heroism on the part of Francis de Sales that he ventured to visit that part of his diocese. General interest was excited by the explorations of Pococke and Wyndham, who published an account of their adventures in the *Transactions of the Royal Society* for 1741. They were followed by Saussure (1760), De Luc (1774), Bonrit (1775) and others; and the number of visitors gradually increased, until the valley became the place of resort it now is.

CHAMPAGNE, a former province of the kingdom of France, with an area of about 10,500 square miles, bounded on the N. by Liège and Luxembourg, on the E. by Lorraine, on the S. by Burgundy, and W. by Isle de France and Picardy. It now forms the departments of Ardennes, Marne, Aube, and Haute Marne, with part of Seine-et-Marne, Meuse, Aisne, and Yonne. The details in regard to its physical features will be found under these separate headings. It was divided into three principal parts, Lower Champagne, Upper Champagne, and Brie. Of these the first comprised Champagne Proper, Sénonais, Vallage, and Bas-

signy, Champagne Proper being the central district, which included the towns of Troyes, Châlons-sur-Marne, Vertus, La Fère, Pleurs, Plancy, Arcis-sur-Aube, Pont-sur-Seine, Nogent, Villemaure, and Aumont. That portion of the district which extended from near Rheims in the N. to near Troyes in the S., was further distinguished as Champagne Pouilleuse, on account of the poverty of its soil. Upper Champagne comprised the districts of Rethelois, Rémois, and Pertois, of which the chief towns were respectively Rethel and Mézières, Rheims and Rocroy, Vitry and Saint-Dizier; while Brie included Meaux, Château-Thierry, Coulommiers, Sézanne, Provins, and Bray-sur-Seine. Physically the province belonged for the most part to what is known as the great basin of Paris, only a small part being drained by the Meuse. The

Sketch-Map of Champagne.

eastern portion has consequently the greatest elevation, and the whole surface has a general slope to the west. The principal heights are the mountains of the Meuse, the Forest of Argonne, and the Western Ardennes, which reach an altitude of 1000 or 1500 feet, but have a very irregular formation. The greater part of the province consists of undulating plains, broken here and there by small clusters of gently swelling hills. Its wines have made its name known over the world. The most valuable grape-districts are the arrondissements of Rheims and Eprenay in the department of Marne; and the wine trade is principally centred in Rheims, Eprenay, Avise, and Châlons-sur-Marne.

Champagne, which in the time of the Romans was inhabited by the Lingones, the Sinones, the Remi, the Tricasses, and the Catalauni, began to be known by its modern name of Campana, or the Plain-Country, in the 6th century, when it formed a duchy of the kingdom of Austrasia. During the 9th century it was part of the great countship of Vermandois, and on the disintegration of that domain about 943, it took the rank of an independent countship. In 1030 the title passed to the house of Blois in the person of Odo II.

who was succeeded by Stephen II., Theobald I., Hugh I., Theobald II., surnamed the Great, Henry I., Henry II., Theobald III., Theobald IV., Theobald V., and Henry III. Of these the most important was Theobald IV., famous for his romantic passion for Blanche of Castile, his political versatility, and his poetic skill. By the death of Henry III., who was also king of Navarre, Champagne passed into the hands of his daughter Jeanne, who afterwards married Philip the Fair of France. Assigned to her son Louis (Hutin), it was united to the royal domain on his accession to the throne of France in 1314. By Philip VI. it was incorporated with the kingdom, and it has ever since been one of the most important and truly national districts of France. Its frontier position and its physical configuration have made it the scene of military operations in almost all the French invasions, and more especially in the Austrian war of the 16th century, the campaign of 1814, and the Prussian war of 1870. During the wars of religion it was governed by the Guises, and sided with the Catholic party; and on the accession of Henry IV. it was one of the last provinces to recognize his legitimacy. Up to the Revolution it formed one of the twelve governments of France, and was within the jurisdiction of the parliament of Paris. Its various bailliages were governed by separate "Contumes," those of Troyes, Meaux, and Chaumont, being remarkable for the transmission of nobility by the female side.

See Baugier, *Mémoires historiques de la province de Champagne*, 1721; Pithou, *Mém. des comtes héréditaires de Champagne et de Brie*, 1572; Deberey, *Recherches sur Champagne*; Beraud, *Hist. des comtes de Champagne et de Brie*, 1839; Arbois de Jubainville, *Hist. des ducs et des comtes de Champagne*, 1859-63.

CHAMPAGNE, PHILIPPE DE (1602-1674), a celebrated painter, was born at Brussels of a poor family. He was a pupil of Fouquier; and, going to Paris in 1621, was employed by Du Chesne to paint along with Nicholas Poussin in the palace of the Luxembourg. His best works are to be found at Vincennes, and in the church of the Carmelites at Paris, where is his celebrated Crucifix, a signal perspective success, on one of the vaultings. After the death of Du Chesne, Philippe became first painter to the queen of France, and ultimately rector of the Academy of Paris. As his age advanced and his health failed, he retired to Port Royal, where he had a daughter cloistered as a nun, of whom he painted a celebrated picture, highly remarkable for its solid unaffected truth. This, indeed, is the general character of his work,—grave reality, without special elevation or depth of character, or charm of warm or stately colour. He painted an immense number of paintings, dispersed over various parts of France, and now over the galleries of Europe. Philippe was a good man, indefatigable, earnest, and scrupulously religious. He died on the 12th August 1674.

CHAMPÁRAN, a British district in the Behar Province, under the jurisdiction of the Lieutenant-Governor of Bengal, lies between 26° and 28° N. lat., and between 84° and 86° E. long. It is bounded on the N. by the independent state of Nepal; on the E. by the River Baghmattí, which separates it from the district of Tirhut; on the S. by the district of Sárán and the Bará Gandak River; and on the W. by the Oudh district of Gorakhpur. A broad grass-covered road or embankment defines the Nepal frontier, except where rivers or streams form a natural boundary. The district is a vast level except in the north and north-west, where it undulates, and gradually assumes a rugged appearance as it approaches the mountains and forests of Nepal. Wide uncultivated tracts cover its north-western corner; the southern and western parts are carefully cultivated, and teem with an active agricultural population. The principal rivers are the Bará or Great Gandak, navigable all the year round, the Chhotá or Little Gandak, Panch Nadi, Lálbagiá, Kojá, and Teur. Old beds of rivers intersect Champáran in every direction, and one of these forms a chain of lakes which occupy an area of 139 square miles in the centre of the district. Of the total area of Champáran, viz., 3531 square miles, 2350 square miles are cultivated, 433 are grazing lands, and the rest uncultivable waste. The population in 1872 amounted to 1,440,815 persons, living in 2299 villages and

242,228 houses. Of these the Hindus numbered 1,240,264, or 86.1 per cent.; Muhammadans, 199,237, or 13.8 per cent.; Christians, 1307 or 1 per cent.; and persons of unspecified religion, 7. Only two towns contain upwards of 6000 inhabitants:—(1) Motihári, the headquarters of the district, population 8266; and (2) Bettiah, population 19,708. The principal crops are rice, Indian corn, barley, sugar-cane, opium, indigo; the mineral products,—gold, copper, and limestone. Gold is washed, generally in minute particles, but sometimes in nuggets of the size of a pea, in the sandy beds of the rivers flowing from the hills. Indigo, saltpetre, and rope form the only manufactures of the district, the first being chiefly conducted with European capital. The revenue of the district in 1870 was £82,159, of which the land revenue yielded £52,030, or 63 per cent.; the civil expenditure was £20,613. In 1872, Champáran had 78 schools under Government inspection, attended by 1222 pupils, costing £293, to which the state contributed £153. Champáran, with the rest of Bengal and Behar, was acquired by the British in 1765. Up to 1866 it remained a subdivision of Sárán. In that year it was separated and formed into a separate district.

CHAMPEAUX, WILLIAM OF, or *Gulielmus Campellensis*, a scholastic philosopher and theologian, so called from his birthplace, the village of Champeaux, near Melun, was born about 1070, and died in 1121. After studying under the realist Anselm of Laon, and the nominalist Roscellin, he commenced to teach in the school of the cathedral of Nôtre Dame, of which he was made canon in 1103. Many scholars gathered round him, and among them was Abelard, who was to prove his great and victorious adversary. In 1108 William, whose attempts to silence his rival had been all in vain, retired into the abbey of St Victor, where he soon resumed his lectures. He afterwards became bishop of Châlons-sur-Marne, and took part in the dispute concerning investitures, on the side of Calixtus II. whom he represented at the conference of Mousson. Of William of Champeaux's works one on the Eucharist has been printed by Mabillon, and the *Moralia Abbreviata* and the *De Origine Animæ* by Martène. In the last of these there is an interesting discussion concerning the fate of children who die unbaptized. He holds that they must be lost, the pure soul being defiled by the grossness of the body; and he silences all objections as to the justice of their condemnation by declaring that God's will is not to be questioned. Ravaisson has discovered a number of fragments by him, among which the most important is the *De Essentia Dei et de Substantia Dei et de tribus ejus Personis*; and a *Liber Sententiarum*, consisting of discussions as to points of ethics and Scriptural interpretation, is also ascribed to him. William of Champeaux is, however, most important as a representative of realism. We possess no works of his own on philosophical subjects, and his views are only to be discovered in the writings of his pupil and rival Abelard. At first he taught that the essence of all the individuals of a genus is the universal (which, as a realist, he held to be an existence independent of the individuals), while the differences between the individuals are not in their essence, but in their accidents. Abelard afterwards—he tells us himself—brought him to admit that there are differences in the essences of different individuals of the same genus, and that the universal is not the whole essence, but only that which is common to the essences of all the individuals—that which exists in them all "*indifferenter*." This admission, though not necessarily involving a surrender of realism, gave rise to suspicions that William was deserting that theory, and it is said that in consequence his popularity greatly diminished.

des Mittelalters; Cousin, *Abélard*; *Histoire Littéraire de la France* (vol. vii. p. 90, and vol. x. p. 307).

CHAMPLAIN, a considerable lake of North America, lying between the States of New York and Vermont, and penetrating for a few miles into Canada. It is 126 miles in length, and from 1 to 15 in breadth, lying nearly north and south, and contains a great number of small islands, most of which belong to Vermont. The Champlain canal, 63 miles in length, connects it with the Hudson; the Sorel, Richelieu, or St John's River forms a natural outlet towards the St Lawrence, and the Chambly canal communicates with the ocean. The lake owes its name to Samuel Champlain the French explorer, by whom it was discovered about 1608; and during the War of 1812-1815 it was rendered famous by the defeat of the English fleet in the engagement of September 11, 1814. Large steamboats and vessels of considerable tonnage navigate Lake Champlain from end to end. The scenery along its shores is highly picturesque, and its waters abound in salmon, salmon-trout, sturgeon, and other fish.

CHAMPLAIN, SAMUEL DE (1567-1635), the governor of the first French settlers in Lower Canada, was born at Brouage, in 1567. His father was a sea-captain, and probably he was already skilled in navigation when, while still young, he entered the army of Henry IV. On the conclusion of the war he accompanied a Spanish fleet to Mexico and the West Indies, and on his return wrote an account of the expedition. In 1603, he made his first voyage to Canada, being sent out by De Chastes, on whom the king had bestowed some territory in that country. During 1604-1607 he was engaged, together with De Monts, to whom De Chastes's privileges had been transferred, in exploring the Canadian coast, in seeking a site for a new settlement, and in making surveys and maps. In 1608 he made his third voyage; and in this year he commenced the formation of a settlement at Quebec. But De Monts's influence was now waning; he had been deprived of some of his privileges; and the merchants who had ventured in the affair were losing heart. Under these circumstances Champlain prevailed upon the Duc de Soissons to interest himself in the matter, and to seek the post of Governor and Lieutenant-General of New France. Under him, and under his successor the duke of Condé, Champlain held the office of lieutenant, which made him in reality governor of the colony. Owing, however, to quarrels with the Indians, the settlement seemed likely to fail; but, under the viceroyalty of the Duc de Montmorenci, and still more under that of the Duc de Ventadour, it began to flourish. In 1629 it met with a reverse, Champlain being forced to surrender to an English fleet commanded by three brothers named Kirk. He was carried to England, but was restored to liberty in 1632. He returned to Canada in the next year, and died there two years afterwards (1635).

Champlain published several volumes containing accounts of his life work. In 1603 appeared his *Des Sauvages*; in 1613 and 1619 *Voyages*, with valuable maps; and in 1632 an abridgment of the first two voyages, with a continuation bringing down his stay to 1629, and appendices containing a treatise on seamanship, and specimens of the Huron and Montagnais languages. In 1870 the whole series of his works was published, with the exception of the very interesting account of his visit to Mexico and the West Indies, which was translated by Alice Wilmore from the MS. kept in the public library at Dieppe, and published by the Hakluyt Society in 1859.

CHAMPOLLION, JEAN FRANÇOIS (1790-1832), one of the earliest and most distinguished of Egyptologists, called *le Jeune* to distinguish him from Champollion-Figeac, his elder brother, was born at Figeac, in the department of Lot, in 1790. He was educated by his brother Champollion-Figeac, professor of Greek at Grenoble, and was then appointed government pupil at the

Lyceum, which had recently been founded. His first work was an attempt to show by means of their names that the giants of the Bible were personifications of natural phenomena. At the age of sixteen (1807) he read before the academy of Grenoble a paper in which he maintained that the Coptic was the ancient language of Egypt. He soon after removed to Paris, where he enjoyed the friendship of Langlès, De Saey, and Millin. Champollion's wonderful acuteness is best displayed by his interpretation of the Rosetta stone, in regard to which there was keen discussion as to the share Dr Young and he respectively had in the discoveries. In 1809 he was made professor of history in the Lyceum of Grenoble, and there published his earlier works. He was sent by Charles X., in 1824, to visit the collections of Egyptian antiquities in the museums of Turin, Leghorn, Rome, and Naples; and on his return he was appointed director of the Egyptian museum at the Louvre. In 1828 he was commissioned to undertake the conduct of a scientific expedition to Egypt in company with Rosellini, who had received a similar appointment from Leopold II., Grand Duke of Tuscany. He remained there about a year. In March 1831, he received the chair of Egyptian Antiquities, which had been created specially for himself, in the Collège de France. He was engaged with Rosellini in publishing the results of Egyptian researches at the expense of the Tuscan and French Governments, when he was seized with a paralytic disorder, and died at Paris in 1832.

He wrote *L'Égypte sous les Pharaons*, 2 vols. 8vo, 1814; *Sur l'écriture hiéroglyphique*, 1821; *Sur l'écriture démotique*; *Précis du système hiéroglyphique*, &c., 1824; *Panthéon égyptien, ou collection des personnages mythologiques de l'ancienne Égypte* (incomplete); *Monuments de l'Égypte et de la Nubie considérés par rapport à l'histoire, la religion, &c.*; 1836, edited by his brother; *Dictionnaire égyptien*, *Dictionnaire copte* and *Dictionnaire copte* (not printed); *Analyse méthodique du texte démotique de Rosette*; *Aperçu des résultats historiques de la découverte de l'alphabet hiéroglyphique* (1827); *Mémoires sur les signes employés par les Égyptiens dans leurs trois systèmes graphiques à la notation des principales divisions du temps*; *Lettres écrites d'Égypte et de Nubie* (1833); and also several letters on Egyptian subjects, addressed at different periods to the Duke de Blacas and others.

CHAMPOLLION-FIGEAC, JEAN JACQUES (1778-1867), elder brother of Jean François Champollion, was born at Figeac, in 1778. He became professor of Greek and librarian at Grenoble, then librarian of the imperial library at Paris, and, when he lost this post in 1828, librarian to Louis Napoleon at Fontainebleau. He edited several of his brother's works, and was also author of a number of original works on philological and historical subjects, among which may be mentioned—*Nouvelles recherches sur les patois ou idiomes vulgaires de la France* (1809), *Annales des Lagides* (1819), *Paléographie ancienne et moderne* (1839-41), *Louis et Charles d'Orléans* (1843).

CHANCELLOR. Various origins have been attributed to this word, so important in its modern use over the greater part of the civilized world; but all of them are of a trivial nature, bearing little reference to the subsequent application of the term. The word *chancel* is connected with the most ordinary and apt of these origins. It supposes the chancellor to have been so called because he sat within a lattice or screen partitioned from the court of justice or hall of audience. There was no such office in the early civil law, and even under the later Western emperors the cancellarius appears to have been a mere subordinate person, a sort of clerk of the chamber, or scribe, who saw the petitioners, and arranged about their business. Gradually he appears to have risen to the rank of an adviser or conscience-keeper, on whose decision the fate of suitors in a great measure depended. In the Eastern empire the chief cancellarius had become a powerful and important officer. As it was the principle of the popedom to be the

spiritual counterpart of the empire, and possess a corresponding hierarchy, the office was imitated at the ecclesiastical court of Rome, and a chancery at the Vatican was repeated throughout the several bishoprics, where each diocese had its chancellor. The great monastic houses too had frequently a chancellor. In the universities an officer of the same name was the connecting-link between those republican institutions and the Romish hierarchy. While the rector was elected by the proctors of the nation or some other corporate constituency, the bishop of the diocese, or in some cases the head of the monastic house to which the university was subordinated, was *ex officio* the chancellor.

It was the ambition of the kings who rose on the fall of the Roman empire, even of those who reigned in Saxon England, to gather round them as many as they could obtain of the attributes of the emperor or basileus, and hence each generally had his cancellarius. In Central Europe the office would naturally descend from the imperial court of Charlemagne; and in France the chancellor became the head of the law and the minister of justice. The office was abolished at the first Revolution. At the Restoration the ministry of justice was made a separate office, and the chief function of the chancellor was to preside in the House of Peers.

It is perhaps in England that we have the most remarkable illustration of the struggle between the influence of the imperial usages and the constitutional spirit of the Northern nations. The existence of common law courts enforcing in its strictness what was deemed the old law of the land, and the chancery with its regal equity interfering to give redress, presents to us the English people with their common lawyers standing up for their rights and privileges, and the monarch, with his clerical advisers, endeavouring to acquire the imperial prerogatives. The chancellor was generally a churchman, who took his ideas of law from the canonists and the civilians, whose principles were intensely disliked by the common lawyers. Hence the two systems called law and equity grew up in antagonism, neither throughout a long contest being able to conquer the other; and hence it is that England has been burdened with the inconvenience of having two systems of jurisprudence, the one called common law, the other equity. The spirit of the former, indeed, may be said to have been so far triumphant in compelling equity to depart from her digressional vagueness, and become a fixed system as securely bound to statute and precedent as the common law itself. But even in Selden's day we find the laxity of the chancellor's equity so much suspected, that he says in his *Table Talk*,—"Equity is a roguish thing. For law we have a measure—know what to trust to: equity is according to the conscience of him that is chancellor, and as that is larger or narrower, so is equity. It is all one as if they should make the standard for the measure we call a foot a chancellor's foot. What an uncertain measure would this be! One chancellor has a long foot, another a short foot, another an indifferent foot; it is the same thing in the chancellor's conscience." How little, indeed, the chancery practice had been at that time moulded into a strict system, we may infer from the seals being held by a churchman, the celebrated Archbishop Williams, and this at the time when the common law had accumulated that amazing mass of intricate precedents which it tasked all the diligence and genius of Coke to reduce into order. Clarendon, when he became chancellor, had been twenty years out of practice, and his successor Shaftesbury had no pretensions to be acquainted with law. Lord Nottingham appears to have been the first who wished to apply strict rules in the court of chancery, but it does not seem to have been in a fit condition for their application. Roger North

says, "He was a formalist; and took pleasure in hearing and deciding, and gave way to all kinds of motions the counsel would offer; supposing that if he split the hair, and with his gold scales determined reasonably on one side of the motion, justice was nicely done—not imagining what torment the people endured who were drawn from the law, and there tost in a blanket." (*Life of Lord Keeper Guildford*, 423). Guildford himself, who, in the words of Lord Campbell, "had as much law as he could contain," made light of the mere judicial business of his office, which ere then, however, had begun to show its characteristic defects, for, according to his biographer, "the greatest pain he endured ensued from a sense he had of the torments the suitors underwent by the excessive charges and delays of the court."

The Lord High Chancellor of Great Britain is a great state officer, with varied and disconnected functions. He is in official rank the highest civil subject in the land out of the royal family, and when raised to the peerage, as he invariably is, he takes precedence immediately after the archbishop of Canterbury. His functions have sometimes been exercised by a "lord keeper of the great seal;" but there appears to be no essential difference between the two offices, save that the keeper is appointed by mere delivery of the seal, which is of itself sufficient to confer all the powers appertaining to the office, while a chancellor receives letters patent along with it. As a great officer of state, the chancellor acts for both England and Scotland, and in some respects for the United Kingdom, including Ireland. As an administrative officer, as a judge, and as head of the law, he acts merely for England. In the first class of functions he acts as prolocutor, speaker, or chairman of the House of Lords, and in this capacity it sometimes falls to him to adjudicate in Scottish law, since he often leads the judgment of the house on appeals. (See *APPEAL*.) By the Treaty of Union, one great seal was appointed to be kept for all public acts. Hence, in this department, the chancellor's authority extends to the whole of Britain, and thus the commissions of the peace for Scotland as well as England issue from him. His English ministerial functions are thus briefly described by Blackstone:—"He became keeper of the king's conscience, visitor, in right of the king, of all hospitals and colleges of the king's foundation, and patron of all the king's livings under the value of twenty marks per annum in the king's books. He is the general guardian of all infants, idiots, and lunatics, and has the general superintendence of all charitable uses in the kingdom." There is much convenience in the repetition of such vague definitions, from the difficulty of more specifically defining the chancellor's functions in these matters. His indistinct and unsatisfactory authority as to charitable foundations has been virtually superseded by the Charity Commissioners' Act of 1853 (17 Vict. cap. 137). The Lord Chancellor is by office a privy-councillor, and it has long been the practice to make him a cabinet minister. Hence he belongs to a political party, and is affected by its fluctuations. This has often been denounced as destructive of the independence and calm deliberateness essential to the purity and efficiency of the bench. In defence, however, of the ministerial connection of the chancellor, it has been said that, while the other judges should be permanent, the head of the law should stand or fall with the ministry, as the best means of securing his effective responsibility to parliament for the proper use of his extensive powers. The addition of permanent judges to the Chancery Court has removed many of the objections to the fluctuating character of the office.

Under the Judicature Act, 1873, the Lord Chancellor is president of the Court of Appeal, and, although the Act is

singularly indefinite on the subject, of the High Court of Justice also. He is named as president of the Chancery Division of the latter court. By the Amendment Act of 1875, he is not to be deemed a "permanent member of the High Court of Justice" within the meaning of the section of the original Act, limiting the number of permanent judges to twenty-one. His judicial patronage is very extensive, and Lord Campbell says that he is by usage the adviser of the Crown in the appointment of judges in the superior courts. His proper title is "Lord High Chancellor of Great Britain and Ireland." His salary is £10,000 per annum, and he is entitled to a pension of £5000 per annum.

In Ireland there is a lord chancellor at the head of the equity system, which arose in minute imitation of the English.

In Scotland a chancellor appears at a pretty early period in history, as the person who, being the adviser and conscience-keeper of the king, issued his writs or letters for the remedy of injustice done by judges or other persons in power. A comparison between the English and the Scottish chancellors of the 13th century would probably show them to have then been much alike. Subsequently, however, the civil law predominating in Scotland, the chancellor was its chief administrator, instead of leading on a system antagonistic to the common law. Hence he became the leading judge of the Court of Session on its establishment in 1533. While Episcopacy predominated he was generally an ecclesiastic, never a working lawyer; and after the Revolution he became an officer of state, who was not expected to be a working lawyer. Hence, when by the Treaty of Union the great seal for public transactions was appointed to be kept in England, the Lord Chancellor of Scotland dropped out of existence. A keeper of the great seal continued to be appointed for sealing writs as to private matters, and the office of director of chancery remained for the transaction of routine business connected with the department. When the method of certifying hereditary successions was simplified and placed on a uniform system in 1848, it was put under the direction of an officer called the Sheriff of Chancery.

The *Chancellor of a Diocese* is an officer who holds the courts of the bishop, and acts as his assessor or adviser in matters of ecclesiastical law. A bishop may be compelled to appoint a chancellor; and there is no appeal from the chancellor to the bishop.

The *Chancellor of the Duchy of Lancaster* is an officer appointed of old chiefly to determine controversies between the king and his tenants of the duchy land, and otherwise to direct all the king's affairs belonging to that court. By late practice, the office, nominally one of high dignity, but demanding little exertion, has been given to statesmen who have grown old in other and more laborious offices, but whose services are still desired in the ministry.

The *Chancellor of the Exchequer* is an officer who, according to the old definitions of his functions, presides in the Exchequer Court, and takes care of the interest of the Crown. He is always in commission with the lord treasurer for the letting of Crown lands, &c., and has power, with others, to compound for forfeitures of lands upon penal statutes. While the treasury is understood to have the custody and distribution of the collected revenue, it is the function of the exchequer to realize it. Hence the Chancellor of the Exchequer, as the head of that department which proposes to parliament the plans for the annual revenue, and sees to its realization, is always an important member of the cabinet. Sometimes he is prime minister. His annual statement of the method by which he proposes to meet the exigencies of the exchequer is called "The Budget." The salary attached to the office is £5000 a year.

CHANCERY, the court of the Lord Chancellor, now consolidated along with the other superior courts in the Supreme Court of Judicature by the Act of 1873. Its origin has been briefly noticed under the head of CHANCELLOR.

It has been customary to say that the Court of Chancery consists of two distinct tribunals—one a court of common law, the other a court of equity. From the former have issued all the original writs passing under the great seal, all commissions of sewers, lunacy, and the like—some of these writs being originally kept in a *hanaper* or hamper (whence the "hanaper office"), and others in a little sack or bag (whence the "petty-bag office"). The court had likewise power to hold pleas upon *scire facias* for repeal of letters patent, &c. "So little," says Blackstone, "is commonly done on the common law side of the court that I have met with no traces of any writ of error being actually brought since the fourteenth year of Queen Elizabeth."

The equitable jurisdiction of the Court of Chancery was founded on the supposed superiority of conscience and equity over the strict law. The appearance of equity in England is in harmony with the general course of legal history in progressive societies. What is remarkable is that, instead of being incorporated with or superseding the common law, it gave rise to a wholly independent set of tribunals. The English dislike of the civil law, and the tendency to follow precedent which has never ceased to characterize English lawyers, account for this unfortunate separation. The claims of equity in its earlier stages are well expressed in the little treatise called *Doctor and Student*, published in the reign of Henry VIII. :—"Conscience never resisteth the law nor addeth to it, but only when the law is directly in itself against the *law of God*, or *law of reason*." So also King James, speaking in the Star Chamber, says, "Where the rigour of the law in many cases will undo a subject, then the chancery tempers the law with equity, and so mixes merey with justice, as it preserves a man from destruction." This theory of the essential opposition between law and equity, and of the natural superiority of the latter, remained long after equity had ceased to found itself on natural justice, and had become as fixed and rigid as the common law itself. The jealousy of the common lawyers came to a head in the time of Lord Ellesmere, when Coke disputed the right of the Chancery to give relief against a judgment of the Court of Queen's Bench obtained by gross fraud and imposition. James I., after consultation, decided in favour of the Court of Equity. The substitution of lay for clerical chancellors is regarded by Mr Spence (*Equitable Jurisdiction of the Court of Chancery*) as having at first been unfortunate, inasmuch as the laymen were ignorant of the principles on which their predecessors had acted. Lord Nottingham is usually credited with the first attempt to reduce the decisions of the court to order, and his work was continued by Lord Hardwicke. By the time of Lord Eldon, equity had become fixed, and the judges, like their brethren in the common law courts, strictly followed the precedents. Henceforward chancery and common law courts have exhibited the anomaly of two co-ordinate sets of tribunals, empowered to deal with the same matters, and compelled to proceed in many cases on wholly different principles. The Court of Chancery could in most cases prevent a person from taking advantage of a common law right, not approved of by its own system. But if a suitor chose to go to a court of common law, he might claim such unjust rights, and it required the special intervention of the Court of Equity to prevent his enforcing them. In many cases also a special application had to be made to chancery for facilities which were absolutely necessary to the successful conduct of a case at common law. Another

source of difficulty and annoyance was the uncertainty in many cases whether the chancery or common law courts were the proper tribunal, so that a suitor often found at the close of an expensive and protracted suit that he had mistaken his court and must go elsewhere for relief. Attempts more or less successful were made to lessen those evils by giving the powers to both sets of courts; but down to the consolidation effected by the Judicature Act, our judicial system justified the sarcasm of Lord Westbury, that we set up one tribunal to do injustice and another to stop it. In one of the last cases, the custody of an infant, which had been granted by the Queen's Bench to one claimant, was transferred by the Court of Chancery to another. The payment of a sum of money into court for the benefit of the child made her a ward of court, and enabled the judge in chancery to apply the principles of equity to the case.

The equitable jurisdiction of chancery was commonly divided into *exclusive*, *concurrent*, and *auxiliary*. Chancery had exclusive jurisdiction when there were no forms of action by which relief could be obtained at law, in respect of rights, which ought to be enforced. Trusts are the most conspicuous example of this class, and are, in fact, the main staple of the business of the court. It also includes the rights of married women, infants, and lunatics. Chancery had concurrent jurisdiction when the common law did not give *adequate* relief, *e.g.*, in cases of fraud, accident, mistake, specific performance of contracts, &c. It had auxiliary jurisdiction when the administrative machinery of the law courts was unable to procure the necessary evidence.

The Judicature Act, 1873, enacts (§ 24) that in every civil cause or matter commenced in the High Court of Justice, law and equity shall be administered by the High Court of Justice and the Court of Appeal respectively, according to the rules therein contained, which provide for giving effect in all cases to "equitable rights and other matters of equity." The 25th section declares the law hereafter to be administered in England on certain points, and ordains that "generally in all matters not hereinbefore particularly mentioned in which there is any conflict or variance between the rules of equity and the rules of the common law with reference to the same matter, the rules of equity shall prevail."

Previous to being merged in the New Supreme Court of Judicature, the Court of Chancery consisted of the Lord Chancellor, the Master of the Rolls, two Lords Justices of Appeal, and three Vice-Chancellors. The Vice-Chancellors and Lords Justices of Appeal are comparatively recent creations.

Notwithstanding the fusion of the courts the great division between common law courts and chancery is not obliterated. The chancery judges form a division by themselves, to which all the pending business of the old court has been transferred, and to which all causes and matters which, but for the Act, would have been within the exclusive jurisdiction of that court are assigned. The Chancery Division still is, and probably will for a long time be, distinguished from the others by the peculiar nature of its business, by the peculiar nature of its administrative arrangements, and by having a separate bar. Another distinction is making itself apparent, and will assume great importance if finally established. The Chancery Division seems to be unwilling to try cases by jury; and in a recent case there has been a direct collision of opinion on this subject between the Chancery and the Common Law Judges.

CHÁNDÁ, a district of British India, in the Nágpur division of the Central Provinces, situated between 19° 7' and 20° 51' N. lat., and 78° 51' and 80° 51' E. long. It is

bounded on the N. by the districts of Raipur, Bhandára, and Wardhá, on the E. by Bastár and Raipur, on the S. by Sironchá, and on the W. by the Wardhá and Pranhítá rivers, which divide it from Berar and the Hyderabad territory. Excepting in the extreme west, hills are thickly dotted over the country, sometimes in detached ranges, occasionally in isolated peaks rising sheer out from the plain. Towards the east they increase in height, and form a broad table-land, at places 2000 feet above sea-level. The Waingangá River flows through the district from north to south, meeting the Wardhá River at Seoní, where their streams unite to form the Pranhítá. The census of 1872 returns the total area of the district at 9700 square miles, and the population at 534,431 souls, residing in 2392 villages and townships, and dwelling in 108,258 houses. Of the total population, 397,540, or 74·39 per cent., are Hindus; 8176, or 1·52 per cent., Muhammadans; 648 or ·12 per cent., Buddhists and Jains; 89, or ·02 per cent., Christians; and 127,978, or 23·95 per cent., aboriginal tribes and people returned in the census report under the heading of "others." Two towns in the district are returned as containing a population of upwards of 5000 souls; viz., Chándá, population 16,233, and Amori, population 5271. Of the total area of the district, 9700 square miles, only 988 were actually under cultivation in 1873-74, 5200 square miles being returned as cultivable, and 3509 as uncultivable waste. The principal crops are rice, wheat, oil-seeds, sugar-cane, and cotton. Within the last few years extensive coal and iron beds have been discovered, and 20 mines were in operation in 1873-74. A branch line of railway will shortly connect the Chándá coal-measures with the Bombay railway system. Dense woods cover the country. Teak grows everywhere; and in the Government forests, in the eastern part of the district, it attains a large size. The chief manufacture of the district is cotton cloths, both of coarse and fine quality, which are largely exported to Western India. Silkworm breeding is largely carried on, and silk or silk and cotton fabrics are woven. Iron smelting is an important branch of industry. The district trade is conducted at annual fairs, which are held at the towns of Chándá, Bhándak, Chímur, Márkandí, and Warhá, and are numerous attended by visitors from all parts of India. The sales effected at these fairs in 1868-69 amounted to £152,224.

Chándá is thickly studded with fine tanks, or rather artificial lakes, formed by closing the outlets of small valleys, or by throwing a dam across tracts intersected by streams. The broad clear sheets of water thus created are often very picturesque in their surroundings of wood and rock. The chief architectural objects of interest are the cave temples at Bhándak, Winjbásaní, Dewálá, and Ghugus; a rock temple in the bed of the Wardhá River below Ballápur; the ancient temples at Márkandí, Ambgáon, and elsewhere; the forts of Wairágarh and Ballápur; and the old walls of the city of Chándá, its system of water-works, and the tombs of the aboriginal Gond kings.

The total revenue of the district in 1873-74 amounted to £38,922,10s., of which £24,402 or 62·7 per cent., was derived from the land. For the education of the people, 67 schools, attended by 3347 pupils, were either entirely supported by the state, or were subsidized under the grant-in-aid rules. For the relief of the sick, 4 charitable dispensaries were maintained, at which 24,448 persons were treated, at a total cost of £660, of which £439 was contributed by Government. The annual rainfall at Chándá town averages 44·67 inches, but in the hilly wooded region to the east it is considerably higher. The rainy season lasts from the middle of June to the end of September. From the middle of September to the close of

November fever of a malarious type prevails all over the district. Cholera and smallpox are also common.

CHĀNDĀ, the principal town in the district of the same name, is situated in 19° 57' N. lat. and 79° 22' E. long., at the junction of the Virāi and Jharpat rivers. The town is surrounded by a wall of cut stone five and a half miles in circuit, and crowned with battlements still in perfect preservation. The town contains a total population of 16,233 souls, classified as follows:—Hindus, 14,350; Muhammadans, 1294; Buddhists and Jains, 53; Christians, 76; and "others," 460. The municipal revenue in 1871 was £1120. The population of the town is chiefly Marbattā and Telingā; the traders, shopkeepers, and craftsmen belong to the latter. The principal manufactures are coarse and fine cotton cloths, silk fabrics, brass utensils, leather slippers, and bamboo work. The town is the seat of considerable external trade, the value of the imports in 1868–69 being returned at £178,044, and the exports at £114,342. The civil station lies a little to the north of the city, having the military cantonments to the west, with the civil lines in the centre and east.

CHĀNDARNAGAR (popularly *Chundernagore*), a French settlement, with a small adjoining territory, situated on the right bank of the River Hugli, 20 miles above Calcutta, in 22° 51' 40" N. lat. and 88° 24' 50" E. long. Chandarnagar has played an important part in the European history of Bengal. It became a French settlement towards the close of the 17th century, but did not rise to any importance till the time of Dupleix, during whose administration more than two thousand brick-houses were erected in the town, and a considerable maritime trade was carried on. In 1757, Chandarnagar was bombarded by an English fleet and captured; the fortifications and houses were afterwards demolished. On peace being established, the town was restored to the French in 1763. When hostilities afterwards broke out in 1794, it was again taken possession of by the English, and was held by them till 1816, when it was a second time given up to the French; it has ever since remained in their possession. All the former commercial grandeur of Chandarnagar has now passed away, and at present it is little more than a quiet suburb of Calcutta, without any external trade. The European town is situated at the bottom of a beautiful reach of the Hugli, with clean wide thoroughfares, and many elegant residences along the river bank. The total area of the territory is only 2330 acres, including a few villages outside the town. The authorities of Chandarnagar are subject to the general jurisdiction of the Governor-General of Pondicherry, to whom is confided the general government of all the French possessions in India.

CHANDLER, RICHARD, D.D. (1738–1810), a British antiquary, was born in 1738, at Elson in Hampshire, and was educated at Winchester school, and Queen's College, Oxford. His first work consisted of fragments from the minor Greek poets, with notes (1759); and in 1763 he published a fine edition of the Arundelian marbles, *Marmora Oxoniensia*, with a Latin translation, and a number of suggestions for supplying the lacunæ. In 1763 Chandler, together with Revett, the architect, and Pars, a painter, was sent by the *Dilettanti Society* to explore the antiquities of Ionia and Greece. After spending above a year in Asia Minor the travellers passed another year in Greece, examining Attica and the Peloponnesus, and returned to England in the end of 1766. The result of their joint investigations was the two magnificent folios of Ionian antiquities published in 1769. Chandler also published a very valuable collection of inscriptions, entitled *Inscriptiones Antiquæ pleraque nondum editæ, in Asia Minore et Græcia, præsertim Athenis, collectæ* (Oxford, 1774). In 1775 he published his *Travels in Asia Minor*;

in 1776 his *Travels in Greece*; and in 1800 his *History of Ilium*, in which he asserted the accuracy of Homer's geography. His *Life of Bishop Waplesley*, Lord High Chancellor to Henry VI., did not appear till after his death, in 1811. After his return from Greece, Chandler obtained several church preferments, including the rectory of Tylchurst, in Berkshire; and after marrying and travelling for some time in Switzerland and Italy, he settled down in England, where he died in 1810.

CHANDLER, SAMUEL, D.D. (1693–1766), a learned Dissenting minister, was born at Hungerford, in Berkshire, where his father was an eminent Nonconformist minister. He was sent to school at Gloucester, where he commenced a life-long friendship with Bishop Butler and Archbishop Secker; and he afterwards studied at Leyden. His talents and learning were such that he was elected fellow of the Royal and Antiquarian Societies, and was made D.D. of Edinburgh and Aberdeen. He also received offers of high preferment in the Established church. These he decidedly refused, remaining to the end of his life in the position of a Presbyterian minister. For some time he preached at Peckham, and for forty years he was pastor of the meeting-house in the Old Jewry. During two or three years, having fallen into pecuniary distress through the failure of the South Sea Scheme, he kept a book-shop in the Poultry. On the death of George II. Chandler published a sermon in which he compared that king to King David. This view was attacked in a pamphlet entitled *The History of the Man after God's own Heart*, in which the author complained of the parallel as an insult to the late king, and, following Bayle, exhibited king David as an example of perfidy, lust, and cruelty. Chandler condescended to reply in *A Critical History of the Life of David*, which is perhaps the best of his productions. This work was just completed when he died, on May 8, 1766. He left 4 vols. of sermons (1768), and commentaries on St Paul's Epistles to the Galatians, Ephesians, and Thessalonians (1777), several works on the evidences of Christianity, and a work on subscription to articles of faith (1748).

CHANG-CHOW, a town of China, in the province of Fuh-keen, on a branch of the River Lung Keang, 35 miles west of Amoy. It is well built, and surrounded with a wall 4½ miles in circumference, which, however, includes a good deal of open ground. The streets are paved with granite, but are very dirty. The river is crossed by a enormous bridge, 800 feet long, constructed of wooden planks supported on 25 piles of stones about 30 feet apart. The city is a centre of the silk-trade, and carries on an extensive commerce in different directions. Brick-works and sugar-factories are among its chief industrial establishments. Its population is estimated at about 1,000,000.

CHANNEL ISLANDS, a number of islands politically attached to Great Britain, but connected with France by geographical position, being situated in the great bay of St Michael, which is bounded by the coasts of the departments of Manche, Ille-et-Vilaine, and Côtes du Nord. They are naturally divided into four principal groups—the northern, which includes Alderney, Burhou, and the Casquets, lying off the Cape de la Hague; the north-central, comprising Guernsey, Herm, and Sark, about eighteen miles to the south-west; the south-central, or Jersey and its adjacencies, more towards the centre of the bay; and the southern, or the Minquiers and Chausseys, with their multitudinous islets. The total area is about 75 square miles, or 48,000 acres.

The geological character of all the groups is in their principal features the same, for the islands consist almost exclusively of igneous rocks in various stages of decomposition. They have been denuded of nearly all the fossiliferous and stratified rocks with which at an earlier period they

would seem to have been covered. The process which has thus stript the islands is still going on around the coasts, wearing the cliffs into caves and gullies, and grinding the rocks into shingle and sand. The tide in St Michael's bay is of very considerable force, and rises to a height of about forty feet at Jersey, and to about thirty at Guernsey, while the difference of high water at spring and neap tides is seventeen feet at the former island and eleven at the latter.

The minerals belonging to granitic rocks are very abundant, such as crystals of felspar and hornblende, and many kinds of quartz and felspar. Asbestos is found, and chlorite is everywhere abundant.

The *flora* of the islands is remarkably rich considering their extent nearly 2000 different species of plants having been counted throughout the group. Of timber properly speaking there is hardly any, but the evergreen oak, the elm, and the beech grow well and are abundant. Wheat is the principal grain in cultivation; but far more ground is taken up with turnips and potatoes, mangold, parsnip, and carrot. The tomato ripens as in France, and the Chinese yam has been successfully grown. There is a curious cabbage, chiefly cultivated in Jersey, which shoots up into a long woody stalk from 10 to 15 feet in height, fit for walking-sticks or palisades. Grapes and peaches come to perfection in green-houses without artificial heat; and not only apples and pears but oranges and figs can be reared in the open air. The arbutus ripens its fruit, and the camellia clothes itself with blossom, as in more southerly climates; the fuchsia reaches a height of 15 or 20 feet, and the magnolia attains the dimensions of a tree. Of the flowers, both indigenous and exotic, that abound throughout the islands, it is sufficient to mention the Guernsey lily with its rich red petals, which is supposed to have been brought from Japan.

The number of the species of the mammalia is little over twenty, and several of these have been introduced by man. There is a special breed of horned cattle, and each island has its own variety, which is carefully kept from all intermixture. The animals are small and delicate, and marked by a peculiar yellow colour round the eyes and within the ears. The red deer was once indigenous, and the black rat is still common in Alderney and Herm. Nearly 300 species of birds have been found, or more than half the whole British list. There are few localities in the northern seas which are visited by a greater variety of fish, and the coasts abound in crustacea, shell-fish, and zoophytes.

Owing to the Norman system of land-tenure being still in force, the land is parcelled out among a great number of small proprietors, and in Alderney, for example, five or eight acres of arable land is accounted a fair estate. The results of this arrangement seem to be favourable in the extreme. Every corner of ground is carefully and intelligently cultivated, and a considerable proportion is allotted to market-gardening. The cottages are neat and comfortable, the hedges well trimmed, and the roads kept in excellent repair. Wealth is for the most part pretty equally distributed, and poverty or pauperism is comparatively unknown. There is a very considerable export and import trade, the value of the produce and manufactures of the islands dispatched to England in 1874 amounting to £459,639, or between £9 and £10 for every acre of land;

Channel Islands.

while the total importation of British and foreign articles reached the sum of £982,656. The population of the whole group has largely increased during the present century, though, on account of exceptional causes, the numbers in Alderney, Sark, and a few of the smaller islands are not so great as they were a few years ago. In 1821 Jersey had 28,600 inhabitants, as compared with 56,627 in 1871; and Guernsey and the dependent islands, inclusive of Alderney, Sark, &c., had 20,827, as compared with 33,699. For further details on the economical condition of the islands the reader may consult the separate articles ALDERNEY, JERSEY, &c.

The language spoken in ordinary life by the inhabitants of the islands is in great measure the same as the Old Norman French, though modern French is used in the law courts, and English is taught in all the parochial schools, and is familiar to a gradually increasing proportion of the population, especially in Jersey and Alderney. The several islands have each its own dialect, differing from that of the others at once in vocabulary and idiom; and a very marked difference is observable between the pronunciation in the north and the south of Guernsey. It has even been asserted that every parish in that island has some recognizable peculiarity of speech; but if this is the case, it is probably only in the same way in which it could be asserted of neighbouring parishes throughout the country. None of the dialects have received much literary cultivation, though Jersey is proud of being the birthplace of one of the principal Norman poets, R. Wace, and has given a number of writers to English literature. The Guernsey patois is rendered pretty well known to the philologist by the *Rimes Guernésaises* of George Métivier, who has since published a *Dictionnaire Franco-Normand, ou Recueil des mots particuliers au dialecte de Guernesey*, 1870; and a fair idea of that of Jersey is obtainable from the *Rimes et Poésies Jersiaises de divers auteurs*, by A. Mourant, 1865.

The original ethnology and pre-Christian history of the Channel Islands are largely matters of conjecture and debate. Of early inhabitants abundant proof is afforded by the numerous megalithic monuments—cromlechs, kistvaens, and menhirs—still extant in various quarters, and it is well known that the number of these memorials was much greater in recent centuries. One of the most important, indeed—a cromlech near St Helier's—was only removed in 1788. But little trace has been left of Roman occupation, and such remains as have been discovered are mainly of the portable description that affords little proof of actual settlement. According to tradition St Mareon or Mareulfus visited the islands as a Christian missionary in 540, and in 568 he was followed by St Magloire (a friend and fellow-evangelist of St Samson of Dol), who founded monasteries at Sark and at Jersey. In 933 the islands were made over by Rodolph of Brittany to William of Normandy, the son of Rollo; and after the Norman conquest of England, their allegiance shifted between the English crown and the Norman coronet according to the vicissitudes of war and policy. During the purely Norman period, they had been enriched with numerous ecclesiastical buildings, some of which are still extant, in a more or less perfect condition. In the reign of John of England, the future of the islands was decided by their attachment to the English crown, in spite of the separation of the duchy of Normandy. To John it has been usual to ascribe a document, at one time regarded by the islanders as their Magna Charta; but modern criticism leaves little doubt that it is not genuine. An unauthenticated "copy" of uncertain origin alone has been discovered, and there is little proof of there ever having been an original; while it is plain that the islands were in possession of several of the privileges which it professes to accord previous to the supposed date. The reign of Edward I. was full of disturbance and trouble; and in 1279 Jersey and Guernsey received from the king, by letters patent, a public seal as a remedy for the dangers and losses which they had incurred by lack of such a certificate. Edward II. found it necessary to instruct his collectors not to treat the islanders as foreigners; his successor, Edward III., fully confirmed their privileges, immunities, and customs in 1341; and his charter was recognized by Richard II. in 1378. In 1343 there was a descent of the French in Guernsey; the governor was beaten, and Castle Cornet besieged. In 1380 Pius IV. issued a bull of anathema against all who molested the islands; it was formally registered in Brittany in 1384, and in France in 1386; and in this way they

acquired the right of neutrality, which they retained till 1689. Henry V. confiscated the alien priories which had kept up the same connection with Normandy as before the Conquest, and conferred them along with the regalities of the islands on the duke of Bedford. During the Wars of the Roses, Queen Margaret, the consort of Henry VI. made an agreement with Maulevrier, the seneschal of Normandy, that if he afforded assistance to the king he should hold the islands independently of the Crown. A force was accordingly sent to take possession of Jersey Castle. Orgueil was captured and a small part of the island subjugated, but the rest held out under Philip de Carteret, and in 1467 the vice-admiral of England, Sir Richard Horbiston, recaptured the castle and brought the foreign occupation to an end. By a charter of 1494, the duties of the governors of Jersey were defined and their power restricted; and the educational interests of the island were furthered in the same reign, by the foundation of two grammar schools by John Neal. The Reformation was heartily welcomed in the islands; and under the influence of French pastors, the form of worship adopted was the Presbyterian. The greatest severity was exercised in the maintenance of the new ecclesiastical discipline. In 1554 one Richard Girard was flogged through the town of St Helier's for defending the doctrine of the mass; in 1576 several persons were thrown into prison by the royal court for not having taken the communion, and they were not to be liberated till they could repeat the commandments and the Lord's prayer; and in 1592 it was enacted that all persons should attend divine service morning and evening under the penalty of a fine.

The Presbyterian form of church government was formally sanctioned in Jersey and Guernsey by Queen Elizabeth; and in 1603 King James enacted that "they should quietly enjoy their said liberty." During the governorship of Sir John Poyton, however, disputes arose between him and the Presbyterian "colloquy" or synod about nomination to benefices, and both parties appealed to the king. A commission was appointed in 1609, but peace was not established. An Episcopal party had been formed in Jersey, and in 1619 David Bandinal was declared Dean of the island. A body of canons which he drew up agreeable to the discipline of the Church of England was accepted after considerable modification by the people of his charge; but the inhabitants of Guernsey maintained their Presbyterian practices. Of the hold which this form of Protestantism had got on the minds of the people even in Jersey abundant proof is afforded by the general character of the worship at the present day. Having taken different courses in religion the two islands naturally attached themselves to different sides in the great struggle between king and parliament. Jersey was for Charles and Guernsey for the Commons. The former island maintained its loyalty till 1651, when the royal cause became hopeless, and even Sir George Carteret, who had been its principal support, was obliged to surrender. Both islands had suffered severely from the struggle, and the people of Guernsey complained that two-thirds of the land was out of cultivation, and that they had lost "their ships, their traffic, and their trading." After the Restoration there was considerable improvement, and in the reign of James the islanders got a grant of wool for the manufacture of stockings—4000 tods of wool being annually allowed to Jersey, and 2000 to Alderney. By William of Orange the neutrality was abolished in 1689, and during the first American War there were two unsuccessful attacks on Jersey. In 1767 an attempt was made to introduce the English custom-house system; but it proved practically a failure, and the islands thrived on smuggling and privateering down to 1800. Since then their history has been one of quiet progress, with no more serious disturbance than can arise from local rivalries.

Heylin, *Relation of two Journeys, 1656*; Philip Falle, *Cæsarea, or an Account of Jersey*, London, 1694, revised edition, 1734; Dicey, *An Hist. Account of Guernsey*, 1750; E. Allen, *Argument to His Majesty's Royal Commissioners in the Island of Jersey*, 1812; Berry, *Hist. of Island of Guernsey*, 1815; Pless, *Account of Jersey*, 1817; Inglis, *Channel Islands*, 1835; Duncan, *Hist. of Guernsey*, 1842; F. B. Tupper, *Chronicles of Castle Cornet, Guernsey*, 1851; Hoskins, *Charles II. in Channel Islands*, 1854; Le Quesne, *Constit. Hist. of Jersey*, 1856; Girardin and Morière, *Rapport d'une Excursion Agricole à Jersey en 1856, 1857*; De la Croix, *Jersey, ses antiquités, ses institutions, &c.*, 1859; D. T. Ansted and R. G. Latham, *The Channel Islands*, 1865. The last work is an interesting compilation, and treats of the islands in their geographical, botanical, zoological, and historical relations. See also a paper in the *Fortnightly Review* (1876) by the Rev. F. Barham Zincke.

CHANNING, WILLIAM ELLERY (1780–1842), was the son of William Channing and Lucy Ellery, and was born at Newport, Rhode Island, U.S., on the 7th of April 1780. The place of his birth is situated amidst scenery of great and varied beauty, the influence of which upon his mind may be traced in many allusions in his writings, and in the vivid admiration which he ever expressed for it in after-

life. To the society of the town of Newport he owed but little; it was a bustling, crowded seaport, where a certain Puritanic strictness, inherited by tradition from the founders of the State, was kept up, not only in connection with, but too much as a salvo for, a considerable amount of laxity both of speech and practice. As a bathing-place it was a resort for strangers from other parts, and the interfusion of French and British officers tended to modify the peculiarities which the unmixed influence of retired sea captains, West Indian traders, and keen New England lawyers might have rendered too strong.

As a child, Channing was remarkable for a refined delicacy of feature and temperament, which made him an object of admiration and affection in the household. From his father he inherited a fine person, simple and elegant tastes, sweetness of temper, and warmth of affection; from his mother (who appears to have been a remarkable woman) he derived the higher benefits of that strong moral discernment and straightforward rectitude of purpose and action which formed so striking a feature of his character. By both parents he was carefully instructed in those strict religious principles which were characteristic of the people of New England; and by both, but especially by his mother, was his moral training most sedulously cared for. Other influences, however, were in the meantime operating upon him. The excitement of the revolutionary war was inspiring him with a profound and ardent love of freedom. The sick chamber of an aunt of his father, who was a woman of much piety and sweetness, was the source of many serious and hallowed lessons of gentleness and goodness. An amateur Baptist preacher, who was by trade a cooper, by refusing, though very poor, to manufacture any of the articles of his trade used for containing ardent spirits, gave him an impulse which he never lost in favour of temperance. A female servant, whose religious views were of a more cheerful cast than those prevalent in his circle, used to talk to him in a way that greatly engaged him, and probably sowed the germ of not a few of the ideas which afterwards regulated his modes of religious sentiment. Able and free-minded men, like Dr Stiles and Dr Hopkins, frequented his father's house, and the quiet and thoughtful boy listened to their conversations, and laid many suggestive words that fell from them to heart. While but a child he had begun to draw inferences from what he heard from the pulpit and elsewhere that were not quite such as his guardians would have wished him to draw; and he "was even then quite a theologian, and would chop logic with his elders according to the fashion of that controversial time," as he himself tells us.

Whilst very young, he was sent to a dame's school, who exacted from the ineipient republicans the title of *Madam*, and enforced her authority and her lessons by means of "a long round stiek." From this he passed under the care of two excellent women, by whose instructions he profited greatly. His next step was to the school of a Mr Rogers, considered the best at that time in the town; and in his twelfth year he was sent to New London to prepare for college, under the care of his uncle the Rev. Henry Channing. His career at school does not appear to have been marked by any remarkable aptitude for letters; on the contrary, his progress was at first somewhat slow, though after the few initiatory difficulties were overcome, he advanced rapidly, both in a knowledge of the classics and an appreciation of their excellencies. His disposition was thoughtful and retiring, though among his companions he showed no absence of relish for lively conversation or hearty amusement. A certain mingled dignity and sweetness gave him a commanding influence in the school, where he went by the name of "the Peacemaker," and "Little V. — 5c

King Pipin," and where he was obeyed, though "small and delicate," with more readiness than mere physical strength could ever have commanded.

Shortly after he went to reside with his uncle, his father died. This event, however, though it produced a great change in the circumstances of the family, was not allowed to interrupt the course of his studies. After the funeral he returned to the house of his uncle, where he remained till he had reached his fifteenth year, when he was removed to Cambridge, Massachusetts, and entered at Harvard College as freshman in 1794. Before leaving New London he came under the influence of a religious revival which took place there, a circumstance to which he was accustomed to trace the commencement of a decidedly religious life.

The four years he remained at college seem to have been most profitably spent. Besides acquiring an extensive acquaintance with classical and general literature, he read largely and thought earnestly in the department of psychology and ethics. The books which appear to have exerted most influence upon his mind and opinions were Price's *Dissertations*, Hutcheson on *Beauty and Virtue*, and Ferguson on *Civil Society*. To the study of Shakespeare also (the interest in whose works was then newly awakened in that quarter) he owed much; and so deep was the impression made on him by the genius of the poet, that to the close of his life one of the greatest of his intellectual treats was furnished by recitations from his writings. By patient and well-directed assiduity he trained himself to the mastery of that copious and vigorous style of composition to which his subsequent position in the world of letters is in no small measure due, and at the same time also laid the basis of his success as a public speaker, by the formal study of rhetoric, and by frequent practice in addressing assemblies of his fellow-students.

For a year and a half after leaving college in 1798, Channing was resident at Richmond, in Virginia, as tutor in the family of Mr David Meade Randolph. Here he had time for study, which he employed chiefly on theological subjects. In regard to many points, touching both the evidences of Christianity and its doctrines, his mind was burdened with doubt and anxiety; and so earnestly did he labour to attain satisfaction, that his constitution sank under the incessant toil. When, in 1800, he returned to Newport, his friends were shocked to find him changed to "a thin and pallid invalid;" and unhappily, at this time were sown the seeds of that depressed condition of health which continued through life his severest trial. He remained in the bosom of his family for another year and a half, engaged in the pursuit of his studies, and in preparing himself, by physical and moral as well as intellectual training, for the work to which he was looking forward—that of the ministry. In 1802 he returned to Cambridge, having been elected to the office of regent in Harvard University, a situation which, without exacting from him any large amount of service, secured to him the advantage of independence, and an opportunity of prosecuting his studies within reach of a valuable library, and under influences favourable to success. In the autumn of 1802 he began to preach, having received approbation to do so from the Cambridge Association; and in the beginning of the following year he accepted the invitation of the Congregational Church, Federal Street, Boston, to be their pastor. To this office he was ordained in June 1803.

Channing entered on his ministry with a deep and almost painful sense of the responsibility of the office he had assumed, and with an earnest desire to acquit himself faithfully of its obligations. His theological views were at this time probably not definitely fixed. We have his own assurance that he was not a Trinitarian, but he had not at this time severed himself from those holding orthodox views.

In 1808 he took part in the ordination of the Rev. J. Codman, a well-known minister of the Congregational order, when he delivered a sermon which was afterwards published. In this sermon, though the language and sentiments are such as any evangelical divine might use, there is nothing that certainly indicates that the author held any of the views peculiarly distinctive of evangelical orthodoxy unless it be the application of the title "Divine Master" to Jesus Christ, and the use of such expressions as that the blood of Christ was "shed for souls," and that for man's salvation "the Son of God himself left the abodes of glory and expired a victim on the cross." It is not thus that Unitarians, in England at least, are wont to speak of Christ and his death. But Channing never identified himself with any theological party. He called himself a Unitarian, and so in a sense he was, but his views were Arian rather than what are commonly known as Unitarian. He revered in Jesus Christ not only a sublimely perfect character, but a nature higher than that of man. He believed in His pre-existence in heaven, and that He came down from heaven for man's salvation; and he taught that "the Scriptures ascribe the remission of sins to Christ's death with an emphasis so peculiar that we ought to consider this event as having a special influence in removing punishment, as a condition or method of pardon, without which repentance would not avail us, at least to that extent which is now promised by the gospel" (*Sermon at the ordination of Rev. Jared Sparks*). The truth is, that Channing was too much a lover of free thought, and too desirous to hold only what he saw to be true, to allow himself to be bound by any party ties. "I wish," he says, "to regard myself as belonging not to a sect but to the community of free minds, of lovers of truth, and followers of Christ, both on earth and in heaven. I desire to escape the narrow walls of a particular church, and to stand under the open sky in the broad light, looking far and wide, seeing with my own eyes, hearing with my own ears, and following Truth meekly but resolutely, however arduous or solitary be the path in which she leads" (*Sermon at Installation of Rev. M. J. Motte*). Thus refusing to be enclosed within the limits of party, and acting freely as respected religious association, he may be claimed as one whom men of all parties honour for his abilities, his integrity, and his work.

In 1814 Channing married his cousin, Ruth Gibbs, a union which brought him an increase of worldly substance, as well as a rich addition to his personal happiness. "Inwardly and outwardly," his biographer tells us, "his lot henceforward was singularly serene." He was now fast rising in reputation, both as a preacher and as a public man. Interested in all that concerned his country and the cause of humanity, his voice was heard on most of the questions that came before the American public, and always with marked and growing effect. He had begun also to command attention as a writer for the press. His *Address on War*, some of his sermons, and especially his able tract on *The Evidences of Christianity*, had given him a position of eminence among the writers of his country. In 1821 he received the title of D.D. from Harvard University. In 1822 he undertook a journey to Europe, in the course of which he visited Great Britain and some parts of the Continent. When in England he made the acquaintance of some distinguished men of letters, especially Wordsworth and Coleridge, on both of whom he appears to have left a most favourable impression. Coleridge wrote of him, "He has the love of wisdom and the wisdom of love." On his return Dr Channing resumed his duties as a minister, but with a more decided attention than before to literature and public affairs. In 1824 he received as colleague the Rev. Ezra Stiles Gannett, at

whose ordination he preached one of his published discourses. From this time forward his energies were devoted, in addition to his pulpit labours, chiefly to the furtherance of great schemes of social reform. Of the anti-slavery cause he was throughout the firm, eloquent, and uncompromising advocate; and in every question that bore upon the happiness of the people he took a lively interest. Of his publications, the most extensively read are his *Remarks on the Life and Character of Napoleon Bonaparte*, his *Remarks on the Character and Writings of John Milton*, his *Essay on the Character and Writings of Fénelon*, his *Essay on Self-Culture*, and his *Essay on the Importance and Means of a National Literature*. He died in the sixty-third year of his age, on Sunday, the 2d of October 1842, whilst on a journey, at Bennington, Vermont, and was buried at Boston, on the 7th of that month. An extended memoir of him by his nephew, William Henry Channing, appeared in 1848 (republished in 1870). His *Complete Works* were published in 2 vols., London, 1865. (W. L. A.)

CHANTIBAN, a large town of Siam, the capital of a province of the same name, on the south bank of a small river near its mouth in the Gulf of Siam, 150 miles S.E. of Bangkok, in 12° 45' N. lat. and 102° 18' E. long. It is the seat of one of the Siamese arsenals, and has a considerable export trade in pepper, cardamoms, rosewood, dyewoods, ship-timber, hides, horns, and ivory. In the vicinity there are mines of precious stones. The population, which is estimated at 30,000, contains a large proportion of Chinese traders.

CHANTILLY, a small town of France, in the department of Oise, 25 miles north of Paris by the main line of the great northern railway. It is finely situated near the River Nonette, and is one of the favourite Parisian resorts. Its name has long been associated with the manufacture of lace and blonde, and it is still more celebrated for its châteaux and pleasure grounds, and as the scene of the great annual races of the French Jockey Club. The old castle must have been in existence in the 13th century, and in the reign of Charles VI. the lordship belonged to Pierre d'Orgemont, Chancellor of France. In 1484 it was transferred by his grandson to the house of Montmorency, and in 1632 it passed from that family to the house of Condé. The Prince de Condé, surnamed the Great, was specially attached to the spot, and did a great deal to enhance its beauty and splendour. Here he enjoyed the society of La Bruyère, Racine, Molière, La Fontaine, Boileau, and other great men of his time; and here his steward Vatel killed himself in despair, because something had gone wrong with the preparations for the reception of his majesty Louis XIV. Of the two splendid mansions that then existed, and were known as the Grand Château and the Petit Château, the former was destroyed about the time of the Revolution, but the latter still remains as one of the finest specimens of the Renaissance architecture in France. On the death of the duke of Bourbon, the last representative of the house of Condé, the estate passed into the hands of the Duc d'Aumale, fourth son of Louis Philippe. In 1853 the house of Orleans was declared incapable of possessing property in France, and Chantilly was accordingly sold by auction. Purchased by the English bankers Coutts & Co. for the sum of 11,000,000 francs, it has since passed back into the hands of the duke. There is a hospital in the town, built and endowed by the last Prince de Condé, and the parish church contains the grave of the Admiral Coligny, who perished in the massacre of St Bartholomew. Among the modern buildings is an Episcopalian church, erected for the English residents, who are mainly jockeys or grooms. Population in 1872, 3461. See Du Cerceau-Perelle; Mérimé, *Promenade des Jardins de Chantilly*, 1791; and Fauquemprez, *Histoire de Chantilly*, 1840.

CHANTREY, SIR FRANCIS (1782-1841), a sculptor of repute, was born on 7th April 1782, at Norton, near Sheffield, where his father cultivated a small property of his own. His father died when he was eight years of age; and, his mother having married again, his profession was left to be chosen by his friends. In his sixteenth year he was on the point of being apprenticed to a lawyer in Sheffield, when, having seen some wood-carving in a shop-window, he requested to be made a carver instead of a solicitor, and was accordingly placed with a Mr Ramsay, wood-carver in Sheffield. When in this situation, he became acquainted with Mr Raphael Smith, a distinguished draftsman in crayon, who gave him lessons in painting; and Chantrey, eager to commence his course as an artist, procured the cancelling of his indentures, and went to try his fortune in Dublin and Edinburgh, and finally in London. Here he first obtained employment as an assistant wood-carver, but at the same time devoted himself to portrait-painting, bust-sculpture, and modelling in clay. The sculptor Nollekens showed particular zeal in recognizing his merits. His first imaginative work was the model of the head of Satan, which was exhibited at the Royal Academy in 1808. He afterwards executed for Greenwich Hospital four colossal busts of the admirals Duncan, Howe, Vincent, and Nelson; and so rapidly did his reputation spread that the next bust which he executed, that of Horne Tooke, procured him commissions to the extent of £12,000. From this period he was almost uninterruptedly engaged in professional labour. In 1819 he visited Italy, and became acquainted with the most distinguished sculptors of Florence and Rome. He was chosen an associate, and afterwards a member, of the Royal Academy (1816 and 1818), received the degree of M.A. from Cambridge, and that of D.C.L. from Oxford, and in 1837 was knighted. He died after an illness of only two hours' duration, on the 25th November 1841, having for some years suffered from disease of the heart, and was buried in a tomb constructed by himself in the church of his native village. The works of Chantrey are extremely numerous. The principal are the statues of Washington in the State-house of Boston, of George III. in London, of George IV. at Brighton, of Pitt in Hanover Square, London, of Watt in Westminster Abbey and at Glasgow, of Roscoe and Canning at Liverpool, of Dalton at Manchester, of Lord-President Blair and Lord Melville in Edinburgh, &c. Of his equestrian statues the most famous are those of Sir Thomas Munro at Calcutta, and the Duke of Wellington in front of the London Exchange. But the finest of Chantrey's works are his busts, and his delineations of children. The figures of two children asleep in each other's arms, which form a monumental design in Lichfield Cathedral, have always been lauded for beauty, simplicity, and grace. So is also the statue of the girlish Lady Louisa Russell, represented as standing on tiptoe and fondling a dove in her bosom. Both these works, it should, however, be explained, were executed from designs by Stothard; for Chantrey knew his own scantiness of ideal invention or composition, and on system sought aid from others for such attempts. In busts, his leading excellence is facility—a ready unconstrained air of life, a prompt vivacity of ordinary expression. Allan Cunningham and Weekes were his chief assistants, and were indeed the active executors of many works that pass under Chantrey's name. Chantrey was a man of warm and genial temperament, and is said to have borne a noticeable though commonplace resemblance to the usual portraits of Shakespeare. He bequeathed his valuable collection, and his whole fortune, after the death of Lady Chantrey, to the Royal Academy, for the encouragement of British sculpture and painting. It is but very recently that this bequest has taken actual

effect; and the precise form in which the Academy mean to administer the trust still (1876) remains indefinite.

CHAPELAIN, JEAN (1595–1674), a French poet and man of letters, was the son of a notary, and was born in Paris. His father destined him for his own profession; but his mother, who had known Ronsard (she was the daughter of a certain Michel Corbière, an intimate friend of the great poet), had determined otherwise. At an early age Chapelain began to qualify himself for literature, acquiring by his own unaided efforts, not only Greek and Latin, but also Italian and Spanish, and even applying himself to medicine. Having finished his studies, he was engaged for a while in teaching Spanish to a young nobleman. He was then appointed tutor to the two sons of a M. de la Trousse, grand provost of France. Attached for the next seventeen years to the family of this gentleman, the administration of whose fortune was wholly in his hands, he seems to have published nothing during this period, yet to have acquired a great reputation as a probability. His first work given to the public was a preface for the *Adone* of Marini, who printed and published that notorious poem at Paris. This was followed by an excellent translation of Mateo Aleman's novel, *Guzman de Alfarache*, and by four extremely indifferent odes, one of them addressed to the great Richelieu, whom Chapelain had the honour of grounding in the dramatic unities. Rewarded with a pension of a thousand crowns, and appointed from the first a member of the newly-constituted Academy, Chapelain drew up the plan of the grammar and dictionary, the compilation of which was to be a principal function of the young institution, and at Richelieu's command prepared a criticism of the *Cid*. In 1756 he published, in a magnificent form, the first twelve cantos of his celebrated epic *La Pucelle*, on which he had been engaged during twenty years. His reputation at this time was so great that six editions of the poem were disposed of in eighteen months. But this was the end of Chapelain, "the legist of Parnassus." The epigrams of Montдор and Furetière, the slashing satire of Boileau (in this case fairly master of his subject), had done their work, and Chapelain ("le plus grand poète-Français qu'ait jamais été et du plus solide jugement," as he is called in Colbert's list) had taken his place among the failures of modern art. The last twelve cantos of *La Pucelle* were never published. A complete manuscript of it exists, with corrections and a preface in the author's autograph, in the *Bibliothèque Nationale*; but its readers, it may be presumed, are few.

In 1662 Chapelain was employed by Colbert to draw up an account of contemporary men of letters, destined to guide the king in his distribution of pensions. In this pamphlet, as in the extracts from his letters published by Camusat in 1726 (*Mélanges de Littérature tirés des Lettres manuscrites de Chapelain*), he shows to far greater advantage than in his unfortunate epic. His prose is said to be incomparably better than his verse; his criticisms are remarkable for their justice and generosity; his erudition and kindliness of heart are everywhere apparent; the royal attention is directed alike towards the author's firmest friends and bitterest enemies. The man, indeed, appears to have been as excellent as the poet was worthless. He does not seem to have known jealousy; Corneille was the object of his warmest praises; and to him the young Racine was indebted not only for kindly and seasonable counsel, but also for that pension of six hundred livres which was so useful to him. Moving in the best society, polite and literary, and loaded with honours and pensions, in his old age Chapelain is reported to have become a miser of the most sordid type, the clothes he wore being so patched and clouted as to procure for him the nickname of the Chevalier de l'Araignée; while Ménage relates that,

calling upon the old man after a long estrangement, he found on the hearth the same cinders that he had remarked thereon twelve years before. His avarice, moreover, is said to have been indirectly the cause of his death, which happened in his seventy-ninth year. Some 50,000 crowns, a large fortune for those days, were found in his apartments.

As a poet, Chapelain seems to occupy on the French side of Parnassus a place analogous to that one filled on the English side by Sir Richard Blackmore. *La Pucelle* is an enormous allegorical nightmare, towards a correct appreciation of which the satire of Boileau is said to be the best guide. As a prose-writer and critic, Chapelain seems to have had real merit; in a passage of his, concerning the legendary epic of the Middle Ages, quoted by Sainte-Beuve (who calls him "homme instruit, sinon poète"), he would appear to have anticipated much of what modern criticism has had to say on the subject.

CHAPEL-HILL, a village of the United States, in Orange County, North Carolina, 27 miles north-west of Raleigh. It is the seat of the North Carolina university, founded in 1789, and has about 2800 permanent inhabitants.

CHAPMAN, GEORGE, translator of Homer, dramatist, and gnostic poet, was born in 1559, and died in 1634. At fifteen, according to Anthony Wood, "he being well grounded in school learning, was sent to the university" of Oxford; at thirty-five he published his first poem, *The Shadow of Night*. Between these dates, though no fact has been unearthed concerning his career, it is not improbable that he may have travelled in Germany. At thirty-nine he was reckoned "among the best of our tragic writers for the stage;" but his only play published at that age was a crude and formless attempt at romantic comedy, which had been acted three years before it passed from the stage to the press; and his first tragedy now extant in print, without name of author, did not solicit the suffrage of a reader till the poet was forty-eight. At thirty-nine he had also published the first instalment of his celebrated translation of the *Iliad*, in a form afterwards much remodelled; at sixty-five he crowned the lofty structure of his labour by the issue of an English version of the *Hymns* and other minor Homeric poems. The former he dedicated to Robert Devereux, Earl of Essex, the hapless favourite of Elizabeth; the latter to Robert Carr, Earl of Somerset, the infamous minion of James. Six years earlier he had inscribed to Bacon, then Lord Chancellor, a translation of Hesiod's *Works and Days*. His only other versions of classic poems are from the fifth satire of Juvenal and the *Hero and Leander* which goes under the name of Musæus, the latter dedicated to Inigo Jones. His revised and completed version of the *Iliad* had been inscribed in a noble and memorable poem of dedication to Henry Prince of Wales, after whose death he and his *Odyssey* fell under the patronage of Carr. Of the manner of his death at seventy-five we know nothing more than may be gathered from the note appended to a manuscript fragment, which intimates that the remainder of the poem, a lame and awkward piece of satire on his old friend Jonson, had been "lost in his sickness."

Chapman, his first biographer is careful to let us know, "was a person of most reverend aspect, religious and temperate, qualities rarely meeting in a poet;" he had also certain other merits at least as necessary to the exercise of that profession. He had a singular force and solidity of thought, an admirable ardour of ambitious devotion to the service of poetry, a deep and burning sense at once of the duty implied and of the dignity inherent in his office; a vigour, opulence, and loftiness of phrase, remarkable even in that age of spiritual strength, wealth, and exaltation of thought and style; a robust eloquence, touched not un-

frequently with flashes of fancy, and kindled at times into heat of imagination. The main fault of his style is one more commonly found in the prose than in the verse of his time,—a quaint and florid obscurity, rigid with elaborate rhetoric and tortuous with labyrinthine illustration; not dark only to the rapid reader through closeness and subtlety of thought, like Donne, whose mis-called obscurity is so often "all glorious within," but thick and slab as a witch's gruel with forced and barbarous eccentricities of articulation. As his language in the higher forms of comedy is always pure and clear, and sometimes exquisite in the simplicity of its earnest and natural grace, the stiffness and density of his more ambitious style may perhaps be attributed to some pernicious theory or conceit of the dignity proper to a moral and philosophic poet. Nevertheless, many of the gnomic passages in his tragedies and allegoric poems are of singular weight and beauty; the best of these, indeed, would not discredit the fame of the very greatest poets for sublimity of equal thought and expression: witness the lines chosen by Shelley as the motto for a poem, and fit to have been chosen as the motto for his life.

The romantic and sometimes barbaric grandeur of Chapman's Homer remains attested by the praise of Keats, of Coleridge, and of Lamb; it is written at a pitch of strenuous and laborious exaltation, which never flags or breaks down, but never flies with the ease and smoothness of an eagle native to Homeric air. From his occasional poems an expert and careful hand might easily gather a noble anthology of excerpts, chiefly gnomic or meditative, allegoric or descriptive. The most notable examples of his tragic work are comprised in the series of plays taken, and adapted sometimes with singular licence, from the records of such part of French history as lies between the reign of Francis I. and the reign of Henry IV., ranging in date of subject from the trial and death of Admiral Chabot to the treason and execution of Marshal Biron. The two plays bearing as epigraph the name of that famous soldier and conspirator are a storehouse of lofty thought and splendid verse, with scarcely a flash or sparkle of dramatic action. The one play of Chapman's whose popularity on the stage survived the Restoration is *Bussy d'Ambois* (d'Amboise),—a tragedy not lacking in violence of action or emotion, and abounding even more in sweet and sublime interludes than in crabbéd and bombastic passages. His rarest jewels of thought and verse detachable from the context lie embedded in the tragedy of *Cæsar and Pompey*, whence the finest of them were first extracted by the unerring and unequalled critical genius of Charles Lamb. In most of his tragedies the lofty and labouring spirit of Chapman may be said rather to shine fitfully through parts than steadily to pervade the whole; they show nobly altogether as they stand, but even better by help of excerpts and selections. But the excellence of his best comedies can only be appreciated by a student who reads them fairly and fearlessly through, and, having made some small deductions on the score of occasional pedantry and occasional indecency, finds in *All Fools*, *Monsieur d'Olive*, *The Gentleman Usher*, and *The Widow's Tears* a wealth and vigour of humorous invention, a tender and earnest grace of romantic poetry, which may atone alike for these passing blemishes and for the lack of such clear-cut perfection of character and such dramatic progression of interest as we find only in the yet higher poets of our heroic age.

So much it may here suffice to say of Chapman as an original poet, one who held of no man and acknowledged no master, but throughout the whole generation of our greatest men, from the birth of Marlowe well-nigh to the death of Jonson, held on his own hard and haughty way of austere and sublime ambition, not without kindly and

graceful inclination of his high grey head to salute such younger and still nobler compeers as Jonson and Fletcher. With Shakespeare we should never have guessed that he had come at all in contact, had not the keen intelligence of a living critic, Mr Minto, divined or rather discerned him to be the rival poet referred to in Shakespeare's sonnets with a grave note of passionate satire, hitherto as enigmatic as almost all questions connected with those divine and dangerous poems. This conjecture the critic has fortified by such apt collocation and confrontation of passages that we may now reasonably accept it as an ascertained and memorable fact.

The objections which a just and adequate judgment may bring against Chapman's master-work, his translation of Homer, may be summed up in three epithets: it is romantic, laborious, Elizabethan. The qualities implied by these epithets are the reverse of those which should distinguish a translator of Homer; but setting this apart, and considering the poems as in the main original works, the superstructure of a romantic poet on the submerged foundations of Greek verse, no praise can be too warm or high for the power, the freshness, the indefatigable strength and inextinguishable fire which animate this exalted work, and secure for all time that shall take cognizance of English poetry an honoured place in its highest annals for the memory of Chapman. (A. C. S.)

CHAPPE, CLAUDE (1763–1805), a French engineer, and the inventor of the simple French telegraph, was born in Normandy in 1763. His invention consisted of an upright post, on the top of which was fastened a transverse bar, while at the ends of the latter two smaller arms moved on pivots. The positions of these four bars represented words or letters; and by means of machines placed at intervals such that each was distinctly visible from the next, messages could be conveyed through 50 leagues in a quarter of an hour. It was said that Chappe borrowed the design from Hooke and Amontons, and the charge so deeply affected him that, notwithstanding the success of his machine, which had been adopted by the Legislative Assembly in 1792, he was seized with deep melancholia, under which he committed suicide in 1805.

CHAPTAL, JEAN ANTOINE (1756–1832), count of Chanteloup, an eminent French chemist and statesman, born at Nogaret, Lozère, 4th June 1756. At Montpellier, where he first studied chemistry, he obtained his doctor's diploma in 1777, when he repaired to Paris. In 1781, the States of Languedoc founded a chair of chemistry for him at the school of medicine in Montpellier, where he taught with success the doctrines of Lavoisier, in opposition to those of Stahl. The capital he acquired by the death of a wealthy uncle he employed in the establishment of chemical works for the manufacture of mineral acids, alum, white-lead, soda, and other substances. His labours in the cause of applied science were at length recognized by the French Government, which presented him with letters of nobility, and the eordon of the order of Saint Michel. A publication by Chaptal, entitled *Dialogue entre un Montagnard et un Girondin*, caused him to be arrested; but being speedily set at liberty through the intermission of his friends, he undertook, in 1793, the management of the saltpetre works at Grenelle. In the following year he went to Montpellier, where he remained till 1797, when he returned to Paris. After the revolution of the 18th of Brumaire (9th November 1799) he was made a councillor of state by the first consul, and succeeded Lucien Bonaparte as minister of the interior, in which capacity he established a chemical manufactory near Paris, a school of arts, and a society of industries; he also reorganized the hospitals, introduced the metrical system of weights and measures, and otherwise greatly encouraged the arts and sciences. A

misunderstanding between him and Napoleon occasioned Chaptal's retirement from office in 1804; but before the end of that year he was again received into favour by the emperor, who bestowed on him the grand cross of the legion of honour, and made him treasurer to the conservatoire seuate. On Napoleon's return from Elba, Chaptal was made director-general of commerce and manufactures and a minister of state. He was obliged after the downfall of the emperor to withdraw into private life; and his name was for a time removed from the list of the peers of France. In 1816, however, he was nominated a member of the Academy of Sciences by Louis XVIII. Notwithstanding the many vicissitudes of fortune which he underwent, Chaptal continued to promote the interests of science until his death, which took place at Paris, 30th July 1832.

His literary works exhibit both vigour and perspicuity of style; he wrote, in addition to various articles for chemical journals, *Elémens de Chimie*, 3 vols. 8vo, 1790; *Traité sur le Salpêtre*, 8vo, 1796; *Essai sur le Perfectionnement des Arts Chimiques en France*, 8vo, 1800; *Art de faire, de gouverner, et de perfectionner les Vins*, 1 vol. 8vo, 1801; *Traité Théorique et Pratique sur la Culture de la Vigne*, &c., 2 vols. 8vo, 1801; *Essai sur le Blanchiment*, 1801; *Chimie appliquée aux Arts*, 4 vols. 8vo, 1807; *Art de la Teinture du Coton en rouge*, 8vo, 1807; *Art du Teinturier et du Dégraisseur*, 8vo, 1800; *De l'Industrie Française*, 2 vols. 8vo, 1819; *Mémoire sur le Sucre de Betteraves*, 8vo; *Chimie appliquée à l'Agriculture*, 2 vols. 8vo, 1823.

CHAPTER, the community of clergyman connected with a cathedral or collegiate church. See **CATHEDRAL** and **DEAN**.

CHAPU, an important maritime town of China, in the province of Che-keang, 50 miles N.W. of Chinmai, situated in one of the richest and best cultivated districts in the country. It is the port of Hang-chow, with which it has good canal communication, and it was formerly the only Chinese port trading with Japan. The town has a circuit of about five miles, exclusive of the suburbs that lie along the beach; and the Tatar quarter is separated from the rest by a wall. It was attacked and much injured by the British force in 1842, but was abandoned immediately after the engagement.

CHARADE, a trifling species of composition, or quasi-literary form of amusement, which may perhaps be best defined as a punning enigma propounded in a series of descriptions. A word is taken of two or more syllables, each forming a distinct word; each of these is described in verso or prose, as aptly and enigmatically as possible; and the same process is applied to the whole word. The neater and briefer the descriptive parts of the problem, the better the charade will be. In selecting words for charades, special attention should be paid to the absolute quality of the syllables composing them, inaccuracy in trifles of this sort depriving them of what little claim to merit they may possess. The brilliant rhythmic trifles of W. Mackworth Praed are well known. Of representative prose charades, the following specimens are perhaps as good as could be selected:—"My *first*, with the most rooted antipathy to a Frenchman, prides himself, whenever they meet, upon sticking close to his jacket; my *second* has many virtues, nor is its least that it gives its name to my first; my *whole* may I never catch!" "My *first* is company; my *second* shuns company; my *third* collects company; and my *whole* amuses company." The solutions are *Tar-tar* and *Co-nun-drum*. "Acting charades" are simply punning enigmas described dramatically. A brilliant description of this variety of the species will be found in Thackeray's *Vanity Fair*.

CHARCAS. See **SUCRE**.

CHARCOAL, the more or less impure form of carbon obtained from various vegetable and animal materials by their ignition out of contact with air.

Wood Charcoal is a hard and brittle black substance, that retains the form and external structure of the wood from which it is made. It rings when struck, and has a conchoidal fracture; it is infusible, and is not dissolved by water or acids; at ordinary temperatures it is a bad conductor of heat and electricity. Charcoal varies much in degree of compactness, box-wood giving a very solid, and willow a porous variety. Exclusive of its pores, it has a specific gravity of 1.5, or, if made at a high temperature, of 2.0. Charcoal from Scotch fir weighs from 10.3 to 10.9 lb per cubic foot; that made from oak is heavier. Very light charcoal is prepared from dogwood, alderwood, and willow. Charcoal contains, besides carbon, varying (but small) quantities of hydrogen, oxygen, and nitrogen; and when consumed, it yields from 1 to 5 per cent. of ash, or the greater part of the mineral matter contained in the original wood. Charcoal burns without flame, and has in air a calorific intensity of about 2700° C.; its specific heat, according to Regnault, is 0.2411. The higher the temperature to which it has been exposed, the higher is the igniting point of charcoal; and that made at the melting point of platinum requires a temperature of 1250° C. to kindle it.

Fresh-burnt charcoal rapidly absorbs from 9.6 to 18 per cent. of its weight of atmospheric moisture, of which the commercial article usually contains about 12 per cent. It has also a remarkable absorptive action on gases, condensing them within its pores. To the heat thus developed has been attributed the occasional spontaneous ignition of charcoal that has been stacked too soon after manufacture. Recently-made box-wood charcoal absorbs, at 12° C. and 28.5 in. pressure, 90 volumes of ammonia, 85 of hydrochloric acid, 65 of sulphurous anhydride, 55 of sulphuretted hydrogen, 35 of carbonic anhydride, 9½ of oxygen, and 6½ of nitrogen; only 1½ vols., however, of hydrogen (Saussure). The absorptive power for gases is nearly in the ratio of the pressures to which the charcoal is exposed, the temperature being constant.

Charcoal can be made at a temperature as low as 300° C. It is produced in greatest quantity at a heat just sufficient thoroughly to char the wood. The charcoal so made contains a larger percentage of hydrogen, oxygen, and nitrogen than that formed at higher temperatures, and, being readily inflammable, is adapted for the manufacture of gunpowder. The quantity of charcoal obtainable from wood varies according to the nature of the wood employed and the method of manufacture. By distillation 25 to 27 per cent. of the weight of the wood can be obtained. Ordinarily, beech yields about 15 per cent. of its weight, box 20½ per cent. Mr Mushet obtained in his experiments the following percentage composition of various kinds of wood, the amount of each kind taken being 1 lbavoirdupois:—

	Volatile Matter.	Charcoal.	Ashes.
Oak.....	76.895	22.682	0.423
Ash.....	81.260	17.972	0.768
Birch.....	80.717	17.491	1.792
Norway Pine.....	80.441	19.204	0.355
Mahogany.....	73.528	25.492	0.980
Sycamore.....	79.20	19.734	1.066

Chestnut.....	76.804	23.280	0.416

Rumford, who employed a long-continued moderate heat, obtained a much larger quantity of charcoal from wood. During the charring of the wood, pyroligneous or acetic acid, creosote, pyroxylic spirit, and empyreumatic oils are produced, and much carbolic oxide, carbonic anhydride, hydrogen, and water are evolved.

Charcoal can be prepared in a variety of ways. In its purest form it is obtained by the ignition of organic substances such as starch and sugar. That made for powder-mills, as also that produced in acetic acid factories, is the product of the distillation of wood in iron cylinders. In China charcoal is prepared in pits, preferably in a clayey soil. In some parts of Sweden it is made from rectangular piles of wood, the process being regulated by the careful admission of air through holes in the covering of the wood. In Foucauld's process, a portable shroud or *abri* of wood coated with a mixture of loam and grass is used to cover the heap to be charred. In most countries where wood is abundant, charcoal-burning is carried on by firing conical piles of billets of wood, about 12 feet in height, and 10 to 40 feet in diameter, from the top of a central hole or chimney. The wood is felled in winter, and must be tolerably dry; it is built up with the bark outermost, the largest billets being placed in the interior of the pile; over the whole is laid a covering of turf, or of charcoal-dust ("breeze") and soil. The combustion of the wood is conducted from above downwards, and from the exterior towards the centre; so that the charcoal in a half-burnt heap forms an inverted cone. At the sides of the heap are holes for the admission of air, the number and size of which are a matter of importance. The first or "sweating" process lasts three or four days, during which the cover becomes moist with condensed water. The openings round about the base of the pile are then covered, and a series of holes is made about half-way from the top of the heap; as the smoke ceases to issue from these they are closed, and other series of holes are made below, as required. The tarry products which collect towards the close of the operation are removed from the heap by means of gutters or pipes.

Sometimes the base of the heap is made in the shape of a flat funnel, from which proceeds a channel for the tar and acid. When the air-holes of the burning heap no longer emit smoke and flame, they are carefully stopped, and the pile is allowed to cool for two or three days. The charcoal is then drawn, and any pieces which may still be glowing are quenched by plunging them into water or sand. By the above-described method, 128 cubic feet (one cord) of wood yield about 30 bushels of charcoal.

Besides being employed as a fuel, and as a reducing agent in metallurgy, wood-charcoal is applied to a variety of purposes. It is much used in the manufacture of filters, and as a medicine it may be administered in some cases of dyspepsia. On account of the resistance of charcoal to the action of water, stakes for wet soils and the insides of casks are charred previous to use. Charcoal is valuable as an absorbent of noxious effluvia, which it decomposes by bringing them into contact with condensed oxygen within its pores. Its absorbent power is greater than that of spongy platinum, but its efficacy as a promoter of chemical union is not so great. Dr Stenhouse has been able to unite the properties of charcoal and spongy platinum in what he calls "platinized charcoal," which is made by boiling charcoal in a solution of platinic chloride, and then heating it to redness in a closed vessel. This preparation may be employed in ventilators and respirators, and, on account of its oxidizing properties, has been proposed for use as a mild caustic.

Coal-Gas Charcoal, or *Gas-Carbon*, is a dense and pure variety of charcoal, of a greyish black colour, which is

deposited in the inside of gas-retorts. It is used for making the negative poles of Bunsen's batteries.

Lamp Black is a finely-divided form of charcoal, obtained by condensing the smoke of burning resinous and oily substances in cylindrical chambers hung with sackings or sheep-skins. The crude lamp black is purified by heating to redness in closed vessels.

Peat Charcoal.—This variety of charcoal is produced by the carbonization of peat in kilns or circular shafts of brick and stone-work. The ignition is made to proceed from above downwards. Peat may also be economically charred by means of the waste-gas of smelting-furnaces, or of heated gases produced by the combustion of wood. In Bohemia a muffle-like chamber, heated at the sides and end by peat-fires, has been successfully employed,—8 to 9 cubic metres of charcoal being produced from 20 cubic metres of peat, by the consumption of 10 cubic metres of the same, and at a cost of 5s. 2½d. per cubic metro of charcoal. According to Stöckhardt, 100 lb of wood-charcoal will by their combustion evaporate as much water as 113 lb of peat-charcoal. The use of charred peat in some metallurgical operations must depend upon the cost of its preparation. Its friability renders it unfit for the blast-furnace; but it may be advantageously used on blacksmiths' hearths. Hitherto, it has not been employed on an extensive scale, the large amount of ash it produces (45 per cent.) being one objection to its consumption.

Animal Charcoal, or *Bone-Black*, is prepared by igniting fresh and coarsely comminuted bones, which have been previously boiled to remove fat, in closed vessels of iron or earthenware. The bone-black so produced, which weighs about half as much as the bones employed, is hermetically sealed, as soon as made, in iron canisters. Animal charcoal contains of carbon about 14 per cent. in a state of fine division, of calcic phosphate 80 per cent., of calcic carbonate 5 per cent., with nitrogen and minor impurities. It is largely employed as a decolorizing, deodorizing, and filtering agent. It removes many organic substances from their solutions; thus it has been found that whilst the colour of ale can be made paler by its means, the bitterness is at the same time wholly removed. This action of animal charcoal is due to the separation of the particles of carbon by the earthy matter present in it. The precipitant action of bone-black on matters in solution is much greater than that of wood-charcoal. Its decolorizing properties are found to be greatly enhanced by washing with hydrochloric acid and subsequent calcination with potash. A good decolorizing charcoal is made by igniting nitrogenous animal matter, such as horn and clippings of hides, in contact with pearl-ash, and washing the product with water. Animal charcoal can be re-purified after use by treating it with acids; or by putrefying and dissolving out organic impurities, washing, and finally igniting it. Animal charcoal is used as a pigment, more especially in the form of *ivory black*, and also as a manure for vegetable soils; and it has been recommended by Drs Eulenberg and Wohl as an antidote in cases of phosphorus poisoning.

Soc.*, 1871, p. 76; Percy, *Metallurgy*, Lond. 1875; Wanklyn, "On the Process of Combustion which takes place in the Interior of certain Porous Filters," *Chem. News*, vol. xxxiii. p. 243, and vol. xxxiv.

CHARD, a municipal borough and market-town of England, in Somersetshire, with a railway junction, 18 miles south of Bridgewater, and 139 miles from London. It was allowed to return two members to parliament by Edward I., but was deprived of that privilege in the reign of Edward III. The town stands upon an eminence on the south border of the county, is well built, and has a town-

house and market-hall of recent erection. It manufactures lace and woollen goods, and iron and brass wares. Population in 1871, 2400.

CHARDIN, SIR JOHN (1643–1713), a celebrated traveller, was born at Paris in 1643. His father, a wealthy jeweller, gave him an excellent education and trained him in his own art; but instead of settling down in the ordinary routine of the craft, he set out in company with a Lyons merchant named Raisin in 1665 for Persia and India, partly on business and partly to gratify his own inclination. After a highly successful journey, during which he had received the patronage of Shah Abbas II. of Persia, he returned to France in 1670, and there published in the following year *Récit du Couronnement du Roi de Perse Soliman III.* Finding, however, that his Protestant profession cut him off from all hope of honours or advancement in his native country, he set out again for Persia in August 1671. This second journey was much more adventurous than the first, as instead of going directly to his destination, he passed by Smyrna, Constantinople, the Crimea, Caucasia, Mingrelia, and Georgia, and did not reach Ispahan till June 1673. After four years spent in researches throughout Persia, he again visited India, and returned to Europe by the Cape of Good Hope in 1677. The persecution going on in France led him, in 1681, to settle in London, where he was appointed jeweller to the Court, and received from Charles II. the honour of knighthood. In 1683 he was sent to Holland as representative of the English East India Company; and in 1686 he published the first part of his great narrative—*The Travels of Sir John Chardin into Persia and the East Indies, &c.* (London). It was not till 1711, however, that the complete account of his travels appeared, under the title of *Journal du Voyage du Chevalier Chardin*, at Amsterdam. The Persian portion is to be found in vol. ii. of Harris's *Collection*, and extracts are reprinted by Pinkerton in vol. ix. The best complete reprint is by Langlès, Paris, 1811. Sir John Chardin's narrative has received the highest praise from the most competent authorities for its fulness, comprehensiveness, and fidelity; and it furnished Montesquieu, Rousseau, Gibbon, and Helvétius with most important material. Sir John died in London in 1713 and was buried in Westminster Abbey, where his monument bears the inscription *Nomen sibi fecit eundo*.

CHARENTE, an inland department in the south-west of France, comprehending the ancient division of Angoumois, and inconsiderable portions of Saintonge, Poitou, and Limousin. It is bounded N. by the departments of Deux-Sèvres and Haute-Vienne, E. by those of Vienne and Dordogne, and S. and W. by Dordogne and Charente-Inférieure. The greater part of its area of 2295 square miles consists of the valley of the River Charente, which rises in Haute-Vienne, and after a circuitous course passes into the department of Charente-Inférieure, where it falls into the sea opposite Isle-Madame, having received in its progress the waters of the Tardoire, Touvres, Né, Antoine, and Boutonne. The Charente, though rapid, has been artificially rendered navigable, and steamers ply between Angoulême and Saintes, although the tide ascends no higher than the latter town. The surface of the department is comparatively level, and subject to frequent inundations; and in the arrondissement of Confolens alone there are upwards of sixty small lakes. The hills, which belong to the Limousin range, are generally uniform in height, and abound in marine deposits; some of them are covered with chestnut forests, which supply the district with a large amount of fruit. The climate is temperate, and the prevailing winds are the west and south-west. The principal productions are wine, corn, hemp, flax, and potatoes, the wine being largely distilled into brandy, for which the

town of Cognac is famous. Pigs, sheep, and poultry are extensively reared for the consumption of the capital; and the value of the truffles annually brought to market is estimated at several millions francs. The mineral productions consist chiefly of iron, lead, antimony, and gypsum, of which iron and gypsum only are worked to any extent. Among the manufactures paper occupies the foremost place; but canvas, linen cloth, hats, cordage, hoops, and pottery are also made. Charente is divided into five arrondissements, which derive their names from the five principal towns of Angoulême, Cognac, Ruffec, Barbézieux, and Confolens. Angoulême is the chief town. The population in 1872 amounted to 367,520.

CHARENTE-INFÉRIEURE, or LOWER CHARENTE, a maritime department of France, comprehending the old provinces of Saintonge and Aunis, and including the islands of Ré, Oléron, Aix, and Madame. It has an area of 2636 square miles, and is bounded N. by Vendée and Deux-Sèvres, E. by Charente, S. by Gironde, and W. by the Bay of Biscay. The surface is exceedingly flat throughout the whole department, and along the coast-line it is so far depressed as to require in many places the erection of sea-dikes and extensive artificial draining. The facilities of the department for internal communication are greatly increased by the number of navigable streams, the formation of two canals (from La Rochelle to the Sèvre-Niortaise, and from Brouage to Rochefort), and the development of an extensive railway system in the hands of a company known as the Company of the Charentes. The productions very nearly coincide with those of Charente, with this difference—that its wines and brandy are greatly inferior, but its fruits and vegetables greatly superior to those of the upper province. It has also more extensive pasturage, and considerable revenue accruing from the pilchard and oyster fisheries on the coast, but its mineral wealth and manufactures are neither so various nor so productive. The former is confined to iron pyrites and the salt supplied by the marshes along the coast; the latter includes coarse woollen stuffs, leather, soap, earthenware, staves, timber, and chemicals. It has several sheltered bays on the coast, and several good harbours, such as Rochefort, Tonnay-Charente, Royan, and Marais, at which a brisk coasting trade is carried on. There is considerable trade in colonial produce, and ship-building is prosecuted to some extent. The climate is salubrious except along the coast, where fevers and ague prevail. There are six arrondissements, cognominal with the towns of La Rochelle, Rochefort, Marennes, Saintes, Jonzac, and St Jean d'Angély,—La Rochelle being the chief town of the department. The total population in 1872 was 465,653.

CHARENTON-LE-PONT, a town of France in the department of Seine, situated on the right bank of the Marne, near its confluence with the Seine, a short distance south-east of Paris, of which it may almost be regarded as a suburb. It derives the distinctive part of its name from the stone bridge of ten arches which crosses the Marne and unites the town with the village of Alfort, famous for its veterinary school. It has always been regarded as a point of great importance for the defence of the capital, and has frequently been the scene of sanguinary conflicts. Of its fortifications the most important is the Fort de Charenton, which lies on the left bank of the river near Alfort. In the 16th and 17th centuries Charenton was the scene of the ecclesiastical councils of the Protestant party, which had its principal church in the town. At present its most remarkable institution is the lunatic asylum, or Maison de Santé, which was originally founded by Le Blanc in 1664 as a general hospital, and only received its present appropriation by a decree of the tenth year of the Republic. In 1814 the bridge was gallantly defended by

the pupils of the veterinary school against the Austrians and Würtembergers. Population in 1872, 7141.

CHARIOT, in antiquity, was a conveyance used in battle, for the chase, in public processions, and in games. It had two wheels, and was made to be drawn by two horses; if a third or, more commonly, two reserve horses were added, they were attached on each side of the main pair by a single trace fastened to the front of the chariot, as may be seen on two prize vases in the British Museum from the Panathenaic games at Athens, on which *quadrigæ* are represented. On the monuments there is no other sign of traces, from the want of which wheeling round must have been difficult. Immediately on the axle, without springs of any kind, rested the basket or body of the chariot, which consisted of a floor to stand on, and a semicircular guard round the front about half the height of the driver. It was entirely open at the back, so that the combatant might readily leap to the ground and up again as was necessary. There was no seat, and generally only room for the combatant and his charioteer to stand in. The pole was probably attached to the middle of the axle, though it appears to spring from the front of the basket; at the end of the pole was the yoke, which consisted of two small saddles fitting the necks of the horses, and fastened by broad bands round the chest. Besides this the harness of each horse consisted of a bridle and a pair of reins, mostly the same as in use now, made of leather and ornamented with studs of ivory or metal. The reins were passed through rings attached to the collar bands or yoke, and were long enough to be tied round the waist of the charioteer in case of his having to defend himself. The wheels and body of the chariot were usually of wood, strengthened in places with bronze or iron; the wheels had from four to eight spokes and tires of bronze or iron. This description applies generally to the chariots of all the nations of antiquity; the differences consisted chiefly in the mountings. The chariots of the Egyptians and Assyrians, with whom the bow was the principal arm of attack, were richly mounted with quivers full of arrows, while those of the Greeks, whose characteristic weapon was the spear, were plain except as regards mere decoration. Among the Persians, again, and more remarkably among the ancient Britons, there was a class of chariot having the wheels mounted with sharp sickle-shaped blades, which cut to pieces whatever came in their way. This was probably an invention of the Persians; Cyrus the younger employed these chariots in large numbers. Among the Greeks and Romans, on the other hand, the chariot had passed out of use in war before historical times, and was retained only for races in the public games, or for processions, without undergoing any alteration apparently, its form continuing to correspond with the descriptions of Homer, though it was lighter in build, having to carry only the charioteer. On two Panathenaic prize vases in the British Museum are figures of racing *bigæ*, in which, contrary to the description given above, the driver is seated with his feet resting on a board hanging down in front close to the legs of his horses. The *biga* itself consists of a seat resting on the axle, with a rail at each side to protect the driver from the wheels. The chariot was unsuited to the uneven soil of Greece and Italy, and it is not improbable that these nations had brought it with them as part of their original habits from their former seats in the East. In the remains of Egyptian and Assyrian art there are numerous representations of chariots, from which it may be seen with what richness they were sometimes ornamented. The "iron" chariots in use among the Jews appear to have been chariots strengthened or plated with metal, and no doubt were of the form above described, which prevailed generally among the other ancient nations.

CHARITIES. There are few features of English society more remarkable than the strength of its charitable organization. It is not merely that the voluntary contributions of individuals to the purposes usually described as charitable are on the largest scale, but that endowments in aid of every variety of public use abound in all parts of the country. These endowments are mostly of private foundation, and but for comparatively recent legislation, would be almost entirely beyond the cognizance or control of the state. So far, indeed, as real property is concerned, the state has for various reasons discouraged its application to such purposes. During the feudal period of English law, the rights of the lords of the soil were continually being invaded by the alienation of land to ecclesiastical corporations. These societies had perpetual succession, whereby the rights of the superior incidental to the tenancy of individuals were destroyed. It was to prevent such alienations that the Mortmain Acts were passed. The statute De Religiosis, 7 Edward I. st. 2, c. 1, and the statute of Westminster 2d enacted that if any body politic, ecclesiastical or lay, sole or aggregate, should buy or sell lands or by any engine or craft appropriate lauds in such a way that they should in anywise come into mortmain, the lord of the fee might enter within a year of the alienation, and in default of the mesne lord, the land should go to the king. The 15 Ric. II. c. 5 extended this statute to all lands, &c., purchased to the use of guilds and fraternities, &c. When testamentary power over freehold lands was established in the reign of Henry VIII., bodies politic and corporate were expressly excepted from the benefit of the statute. Alienations in mortmain, as they were called, were not absolutely void, but voidable only at the option of the intermediate lords or the king, and the licence of the lords and the king confirmed the alienation. A devise of realty to a corporation was ineffectual, and the land descended to the heir, either for his own use or charged with the trust imposed on it by the intended devise. The preamble to the important statute 43 Eliz. c. 4 gives us an idea of the number and variety of the public objects on which testators and other donors were in the habit of expending their wealth:—"Whereas land, tenements, rents, annuities, profits, hereditaments, goods, chattels, money, and stocks of money have been heretofore given, limited, appointed, and assigned, as well by the Queen and her progenitors as by sundry other well-disposed persons; some for relief of aged, impotent, and poor people; some for maintenance of sick and maimed soldiers and mariners, schools for learning, for schools and scholars in universities; some for repair of bridges, ports, havens, causeways, churches, sea-banks, and highways; some for education and preferment of orphans; some for or towards relief, stock, or maintenance of houses of correction; some for marriages of poor maids; some for supportation, aid, and help for young tradesmen, handicraftsmen, and persons decayed; and others for relief or redemption of prisoners or captives, and for aid or ease of any poor inhabitants, concerning payments of fifteens, setting out of soldiers, and other taxes, which lauds, tenements, &c., have not been employed according to the charitable intent of the givers and founders thereof, by reason of frauds, breaches of trust, &c." The statute gives the Lord Chancellor power to appoint commissioners to inquire into such cases. A charity under the statute has been defined to be a gift to a general public use, which extends to the rich as well as to the poor. By a series of judicial interpretations, the power of devising lands to corporations for charitable uses was established, and the subject of the Mortmain Acts was to a certain extent frustrated.

The Act 9 Geo. II. c. 36 takes notice of the public mischief caused by alienations or dispositions made by languishing or dying persons to uses called charitable uses.

to the disherison of their lawful heirs. It is accordingly enacted that no real property, or money to be laid out in the purchase of real property, shall be transferred in any way in trust for the benefit of any charitable use whatsoever, unless such gift be executed by deed at least twelve months before the donor's death, and enrolled in the Court of Chancery within six months of its execution. Gifts to the universities and colleges are excepted under the Act. Gifts to uses which are superstitious within the Acts of Henry VIII. and Edward VI. are still held to be void.

Many Acts have been passed within the present century for the better regulation of charities. The Lord Chancellor was always understood to have a prerogative jurisdiction, as representing the king, who is *parens patrie*, over these public trusts. The Act of Elizabeth, as we have seen, gave him authority to appoint commissioners of inquiry, and under that Act the Court of Chancery developed some very important doctrines regarding charities. The chancellor's commissions fell into disuse, and it was found more convenient to proceed by way of information on the part of the Attorney-General. It will be easily understood that great abuses must have sprung up under a system of control which was by its very nature casual, litigious, and intermittent. In the case of charitable corporations with visitors of their own, the power of the court to interfere was to a certain extent restricted by the visitatorial jurisdiction. In 1818 began a series of public investigations into charitable funds, which has by no means yet come to an end. At the instance of Lord Brougham, a commission was appointed to inquire into the educational charities, but the universities and large schools were exempted from its operation. A second commission with further powers was appointed under the 59 Geo. III. c. 81, and continued until 1830. Charities under special visitors were still exempted, but this exemption was discontinued when the third commission, under 1 and 2 Will. IV. c. 34, was appointed. In the reports of the commission it is stated that the worst cases of abuse and maladministration were found in charities having special visitors. Grammar schools in that position are described as being especially deplorable. A fourth commission was appointed in 1835. The reports of these various commissions, and of a House of Commons committee on the same subject, called public attention to the abuses of charity administration. After many efforts the Charitable Trusts Act of 1853 was passed. By this and the amending Acts, permanent commissioners were appointed with extensive powers. It is their duty to inquire into the management of charities, and to insist on accounts being laid before them, and they are now enabled to undertake the administrative business in respect of charities which belonged to the Court of Chancery. Contentious business is still remitted into court, but the rest is carried through in the office of the commissioners. In cases requiring such intervention, they send a certificate to the Attorney-General, who takes such proceedings thereon as he may think proper. The universities and their colleges, cathedrals, and generally all charities connected with religious worship, or supported solely by voluntary contributions, are exempted from the jurisdiction of the commissioners. Endowed schools were, by the Endowed Schools Act 1869, handed over to a separate commission, and the powers of the Court of Chancery and Charity Commissioners were restricted with respect to them. More recently the Endowed Schools Commission has been allowed to expire, and its duties have been assigned to the Charity Commission. There are still many charities in England which the powers of the Charity Commissioners do not seem to be able to reach.

CHARITON, of Aphrodisias in Caria, probably one of the last of the Greek erotic writers, lived about the 5th

century A.D., and was the author of a romance entitled *The Loves of Chereas and Callirrhoe*. It has been translated into German and French. The best edition is that by D'Orville, reprinted by Beck, Lips., 1783.

CHARLEMAGNE, or CHARLES THE GREAT, was born in 742, succeeded his father Pepin as king of the Franks in 768, was crowned emperor of the Romans in 800, and died in 814 after an eventful and beneficent reign of forty-six years. His father had divided the Frankish kingdom between him and his younger brother Carloman, but the latter dying in 771, Charlemagne was proclaimed sole ruler. The monarchy he thus inherited was a very extensive one; for, in addition to the Frankish territory, stretching from the Loire to the east of the Rhine, there were Burgundy and Allemannia, which had been incorporated by his ancestors, while almost all round the direct empire of the Franks stretched a group of vassal nations. Aquitaine, Brittany, Frisia, Thuringia, and Bavaria were in more or less close subjection to them. They were, moreover, the protectors of the popes against the Greeks and Lombards, and the champions of Christianity against the Saracens on the south-west and the heathen Saxons of the north-east. In fact, before the accession of Charlemagne the Franks had attained to a real supremacy over most of the Germanic nations, and were the bulwark of the Christianity of the West. This many-sided and lofty position imposed a corresponding complexity of duty on the new king, which he fulfilled with an energy and success almost unexampled in the history of the world, maintaining and extending on all hands the influence of Christian culture, and taking the first steps towards converting the military monarchy of the Franks into an organized polity. His first task was to suppress a rising in Aquitaine. In 772 commenced the great mission of his life, the conquest and conversion of the Saxons, a work which could be effected only after thirty-two years of the fiercest and most passionate warfare. With the doubtful exception of the Frisians, the Saxons were the last remnant of the old Germanic resistance to the military supremacy of the Franks, and the last Germanic champions of the religion of Odin against the onward progress of Christianity. Charlemagne never had much difficulty in vanquishing the badly-organized Saxon forces, and in compelling a temporary or partial submission; but with a loose confederation like the Saxons, which had no definite organization and no properly recognized representative, it was difficult to make a fixed and universally accepted arrangement. Hence the incessant renewal of an apparently decided conflict, and the outcry of the Franks against the treachery of their enemies. The encroachments of the Saxons on his eastern frontier was the occasion of his first expedition, which was directed into the ancient forest of Teutoburg, famous as the scene of the old Germanic resistance to the Romans. Here he stormed the fortress of Ehresburg, overthrew the Irminsul, a mysterious column-shaped idol much revered among the Saxons, destroyed the sanctuary of Odin, and compelled the Westphalian Saxons to submit. Events in Italy now summoned Charlemagne to the other side of the Alps, in order to chastise the Lombards who were invading the possessions of the Pope. The Frankish king was victorious, dethroned Desiderius the Lombard king, and placed the Lombard crown on his own head (774). Meanwhile, the Saxons had profited by his absence to expel the Frankish garrisons, and even to renew their old ravages. Charlemagne immediately set out against them, and in two campaigns enforced the submission of the entire Saxon confederation. In a great Champ-de-Mai at Paderborn the Frankish king, surrounded by his chiefs and by ambassadors from distant nations, received the homage of the Saxon warriors, many thousands of whom submitted to be baptized (777). The Saxons apparently

subdued, Charles crossed the Pyrenees, and received the submission of the country as far as the Ebro. On his return, however, the rear-guard was assailed and cut off by the mountaineers in the pass of Roncesvalles; Roland their leader was slain, and the overthrow of the Franks, transformed and wrought up in every possible way, became one of the great themes of song and romance (778). His march home from Spain had been unseasonably hastened by a general revolt of the Saxons, this time assisted by the Danes. Charles was again easily victorious, but no sooner had he left the country than the Saxons, mad with revenge, and animated by the fiercest national and religious hate, resumed the struggle. Even the massacre of Verden (782), in which 4500 Saxon prisoners were slain in cold blood, served only to intensify the spirit of resistance; but their rude courage was no match for the large and well-disciplined armies of the Frankish king. They were again completely defeated; even Wittikind, the hero of the whole war, was compelled to confess the superiority of the God of Charlemagne, and at Attigny received the rite of baptism (785). His example was generally followed; and the Frankish organization, political and ecclesiastical, was systematically introduced. Germany had become Christian; it was now the Northmen, among whom thousands of Saxons had found refuge, that took up the task of supporting a gradually declining cause. But though this may be looked upon as the deciding act in the drama of old Germanic resistance, there were still many bloody and almost general revolts of the Saxons. To punish these Charles adopted even a more effective method than the planting of Frankish garrisons; thousands of Saxon families were deported into other provinces of the empire, and more loyal subjects introduced to fill the vacant space. It was not till 804 that the last sparks of resistance were quenched.

In the year 788, Bavaria was incorporated with the Frankish empire. Its duke, Thassilo, had more than once incurred the displeasure of Charles by too pronounced measures towards the recovery of his independence, and had even alienated his subjects by schemes of alliance with the heathen Avars and the heretic Greeks. Consequently Charles had no difficulty in dethroning him. This was followed in 791 by a vast and well-organized expedition against the Avars, a savage robber nation of Mongols inhabiting the modern Hungary. The Franks were again victorious everywhere; but other work of a more pressing kind prevented Charles from completing their reduction, which was afterwards effected chiefly by his lieutenants. Their immense circular encampments, or rings, from which they had issued to carry havoc into all the surrounding countries, were forced, and their treasures became the spoil of the Christian armies (798). They submitted; and German colonists were introduced into many of those regions. In this way Pannonia was added to the empire of Charles. Other campaigns carried on at various times by Charlemagne or his lieutenants, on the Elbe and even in Bohemia, against the Danes, the Wends, and the Czechs, still further increased the prestige of the Frankish armies, and enlarged the empire of their great monarch against Slavish and Scandinavian heathendom, while his troops maintained the Spanish march against his south-western enemies, Moslem and Christian, and the duke of Beneventum in Southern Italy was obliged to become his vassal. Thus from the Riber to Sicily, and from the Ebro to the Theiss, the will of Charles was supreme; while over the Slavonic tribes, as far as the Oder or even the Vistula, his influence was felt in no feeble way. The genius and energy of one man had succeeded in arresting the progress of political disintegration, and, in the interest of culture and constructive order, in welding into one great monarchy all the races of continental Germany. It was no wonder that

men who associated the ideas of imperial order and constructive civilization with the name of Rome should have recognized in the monarchy of Charles the restoration of the power of the Cæsars. When, therefore, at Rome, on Christmas eve of the year 800, he was crowned emperor of the Romans, it seemed the natural consummation of his whole career. And when in 801 an embassy arrived with curious presents from Harun-al-Rashid, the great caliph who held in the East the same place as Charles in the West, men recognized it as a becoming testimony to the world-wide reputation of the Frankish emperor.

Charles was far more than an ordinary conqueror. He displayed not less energy in the internal organization and administration of his kingdom than in foreign affairs. The whole empire was divided into districts, presided over by counts, who were responsible for their good government; while in the exposed frontiers or marches, other counts (*Markgrafen*) were stationed with forces capable of defending them. In order to superintend these provincial authorities, to give effect to the royal will, to preserve the due subordination of the outlying portions of the empire to the central power, and in this way to complete and secure the organization of the empire, the *missi dominici*, experienced men both of the laity and clergy, were despatched in all directions. Two great assemblies were held every year,—the Champ-de-Mai, which was a kind of national muster, essentially military, and another in autumn, of the high officials, of a deliberative and advisory nature. In the capitularies (edicts issued as the necessities of the empire required), in his endeavours to promote education, in his organization of the church and the definitive institution of tithes, in the unsuccessful attempt to join the Danube and the Rhine by a canal, he gave proof of the noblest desire to conserve and propagate the culture of former times. Learned men—Eginhard, Paul Warnefried, and, above all, Alcuin—were his intimate friends and teachers; Guizot calls Alcuin his intellectual prime minister.

Charlemagne died on 28th January 814, at Aix-la-Chapelle, and was buried there. The empire created and organized by his genius gradually fell to pieces after his death. His endeavour to resuscitate an old civilization, to engraft the Christian Roman culture on the vigorous stem of the Teutonic races, and to unite all the Germanic tribes in one empire, before the long action of historic influences had stamped upon them a distinct national character—this was to a great extent a failure, because one life-time was too short for its accomplishment. His greatness lies in the nobility of his aim, in the energy and wisdom with which he carried it out during his life, and also in the enduring traces of valuable work which remained notwithstanding the general wreck of his empire; for, though the central organization was swept away, the provincial authorities remained, to be transformed into the new feudal organization of Western Europe, whilst the idea of the revival of the Christian Roman Empire was to be taken up by other sections of the Germanic race. Though the circumstances of his time prevented him from being the founder of a new epoch in history, like Cæsar or Alexander, yet, in the greatness of his character, in his marvellous many-sided activity, and in the magic influence of his name on subsequent generations, he was equal to either.

The works of Charlemagne are—1. His *Capitularies*, first collected by Ansegise, abbot of St Wandrille, the best edition of which is that of Etienne Baluze, Paris, 1677, 2 vols. folio; 2. *Letters*, contained in the collection of D. Bouquet; 3. A *Grammar*, of which fragments are to be found in the *Polygraphia* of Tritheim; 4. His *Testament*, contained in Bouchel's *Bibliothèque du Droit Français*, tom. iii., printed at Paris, 1667, folio; 5. Some Latin poems, e.g., the *Epitaph of Pope Adrian* and the *Song of Roland*; 6. The *Caroline Books*. The great contemporary authority for the

life of Charlemagne is the *Vita Caroli Magni*, by Eginhard, who also writes *Annales*. There is a good *Life*, in English, by G. P. R. James. Sketches of Charlemagne in histories of a more general kind are innumerable; probably the best recent one is to be found in Martin's *Histoire de France*. (T. K.)

CHARLEMAGNE, JEAN ARMAND (1759-1838), a French dramatic author, was born at Bourget in 1759. He was intended for the church, but only remained a few months at the theological seminary. He first became a solicitor's clerk, and then entered the army, and served in the American war of independence. At the age of twenty-four he returned to France, and commenced publishing tracts on social subjects, but it was ten years later before he began to write for the stage. He is the author of a large number of comedies and poems and romances, and of an essay, published in 1794, and entitled *Observations de quelques patriotes sur la nécessité de conserver les monuments de la littérature et des arts*.

CHARLEMONT, a great fortress on the Franco-Belgian frontier, on a rock above the town of Givet. See GIVET.

CHARLEROI, a town of Belgium, in the province of Hainault, about 33 miles south of Brussels, on the Sambre, a navigable tributary of the Meuse. It is the seat of a court of primary instance, and possesses a gymnasium, an academy of painting, a hospital, a parish church dating from the time of Louis XIV., and a prison erected in 1852 in the style of a feudal castle. Situated in the midst of an extensive mining district, it has developed into one of the most important industrial centres in the country, carrying on a large manufacture of glass, iron, cutlery, cotton cloth, and woollen yarn. Several thousand persons are engaged in the nail trade alone; and the forges of Couillet, about two miles from the town, supply a third of the whole quantity of cast-iron produced in the kingdom. In 1870 upwards of 24,000 people were employed in the coal mines of the district; and 3,832,850 tons of coal were brought to the surface. Abundant means of transit are afforded by the railways, which form a junction at the town, and by the Brussels and Charleroi canal, which was opened in 1832, and forms a connection at the capital with the Willebroek canal to Antwerp. In 1866 the population of the town was 12,150.

Charleroi was founded in 1666 by Charles II. of Spain, on the site of the village of Charnoy, which changed its name to the present form in honour of the king. The fortifications, however, which the Spaniards had commenced, were interrupted by the approach of the French, and their completion was due to the genius of Vauban. During the rest of the century it passed more than once from French to Spanish, and from Spanish to French possession; in 1746 it was captured by the prince of Conti, but in 1749 it was restored to the house of Austria. During the Revolutionary War in 1794 it was four times besieged by the French, to whom it was ultimately compelled to surrender on the 25th of June. The following year saw the destruction of the fortifications, but they were restored in 1815.

CHARLES I. (1600-1649), king of England, born at Dunfermline on the 19th November 1600, was the second and favourite son of James I. By the death of his brother Henry, he became Prince of Wales in 1612, but the first public matter of importance in which he was concerned was the Spanish marriage. At first he was quite indifferent to the affair, and in 1622 he was full of a dream that he would lead an army into the Palatinate, and set his dear sister upon her throne. But, by the beginning of the next year, Buckingham had filled him with the romantic notion of setting off, in defiance of all policy, on a private visit to Spain. His conduct while at Madrid displays the weakest side of his character. He took a violent fancy for the Infanta, whom he seriously alarmed by leaping over the wall of the garden in which she was walking, in order that he might enjoy the private conversation which Spanish etiquette refused to permit. With a mixture of infatuation and duplicity, he bore with repeated insults; he allowed his

chaplains to be excluded from the palace, and his retinue to be sent back to England, and gave way to each of the ever-growing demands of the Spanish favourite Olivarez. He promised what he knew he had no power to fulfil, the abrogation of the penal laws against the Catholics within three years; he listened respectfully to the arguments of the Spanish theologians, and promised to listen whenever the princess should require it; he addressed to the Pope a disgraceful letter, which, while binding him to nothing, gave rise to the greatest expectations; and thus he held out hopes of a conversion which, according to his own subsequent declaration, he believed would never take place. At last the Spaniards made up their minds to the match; but, though immediately before leaving Spain Charles swore to carry out the marriage, his ardour had cooled, and Buckingham was throwing cold water on the dying embers. James was persuaded to demand the restoration of the Palatinate to the elector Frederick as an essential preliminary; the match was broken off; and in 1624 Buckingham had arranged a marriage with Henrietta Maria of France. Not the least dishonourable part of Charles's conduct in connection with this affair was his treatment of the earl of Bristol, the English ambassador to Spain. This only too faithful servant of the Crown he was mean enough to subject, at the instigation of his favourite, to a persistent and illegal persecution. On the summons of the second parliament of his reign he commanded that Bristol's writ should be withheld; he sought to punish him in an underhand way by forbidding his attendance; and when the earl continued to insist on his rights, and, after two years of confinement to his house, laid the king's letter before the Lords with a request for leave to impeach the duke, he even accused him of high treason, and employed his personal influence against him. The reason of all this was that Bristol had offended Buckingham; and the faults which were laid against him were really chargeable to his accusers. In the first place, he had been too well deceived by Charles's acting, had imagined that he was really inclined to Catholicism, and had offered, if this were so, to keep the matter secret; and, secondly, he had sought to preserve his country's honour by striving to prevent the capricious rupture of the treaty which had been completed with Spain.

In March 1625 Charles came to the throne. The excited joy with which he had been welcomed home from Spain had given way to suspicion as fuller reports of his conduct spread abroad, and there was now prevalent an anxious dread of the growth of Catholicism. The first Parliament sent Montagu to the Tower for preaching the doctrines of divine right and the real presence; and, as difficulties arose concerning the old method of levying tonnage and poundage, it refused to grant the impost for more than a year. From a paper of Sir John Eliot's,¹ it would seem that this was intended merely as a temporary measure; but to please the duke of Buckingham, Charles dissolved the Parliament, and took a pitiful revenge by making Montagu royal chaplain.

The king was now at the disposal of his favourite, who was full of great and warlike schemes. All were, however, doomed to failure. The English sailors refused to fight against the Huguenots of Rochelle; the expedition against Cadiz was mismanaged from first to last; and, worst of all, the pawning of the crown jewels brought in but a very small sum. It was necessary to summon another Parliament.

But this Parliament was not less determined than the first. The House of Lords vindicated its independence by acquitting the earl of Bristol. The Commons, led by the ardent and eloquent Sir John Eliot, ventured on the bold step of exhibiting eight articles of impeachment

¹ See Forster's *Sir John Eliot*, vol. i. p. 214.

against the duke of Buckingham. His majesty replied with a haughty message that the duke had acted only at his direction, threw Eliot and Sir Dudley Digges into prison, and finally dissolved the Parliament again, without any improvement of his finances. Forced loans were resorted to; the common people who refused to pay were pressed for the navy; the gentlemen were summoned before the council, or committed to prison *per speciale mandatum regis*. At this inopportune moment Buckingham provoked a war with France, and led an expedition against Rhé, which proved an utter failure. In 1628 Charles was compelled to call a third Parliament.

The House of Commons which now assembled was remarkable alike for the social standing of its members and for their wealth, which was three times that of the House of Lords. But equally with the other two which had met in this reign, it was determined to obtain redress of grievances. Its first act was to draw up the Petition of Right, which declares the illegality of forced loans, of martial law in time of peace, and of the billeting of soldiers on private houses. Characteristically, Charles at first attempted an evasive reply—"The king willeth that right be done according to the laws and customs of the realm." When, however, the Commons proceeded to censure Buckingham, he gave the regular formal assent. Yet such was his insincerity that he caused 1500 copies of the Petition to be distributed with the first answer attached. The Commons now made known their readiness to vote tonnage and poundage, provided that the king would admit that his arbitrary levy had been illegal; and Hollis and Valentine held the speaker in the chair while Eliot read a protest against Arminians and Papists, and against the irregular levy of tonnage and poundage. A few weeks before, Buckingham had fallen by the dagger of a disappointed officer. But the king's policy was unchanged. The usual plan of dissolution was resorted to; and Eliot, Hollis, and Valentine were heavily fined, and so strictly imprisoned that, though Eliot's health gave way, his petitions for a temporary release were repeatedly refused by Charles, and he was allowed to die in the Tower.

From this time there was no Parliament for eleven years (March 1629 to April 1640). Every year made the people better acquainted with the character of their king, who showed an unhappy ignorance both of the history and the temper of the nation; and taught them to feel more and more deeply that stronger safeguards were needed to withstand the arbitrary power of the sovereign. The London merchant who compared the rule of Charles to that of the sultan of Turkey was not altogether unjust. A paternal government was his *beau-ideal*; and Parliament was to be summoned only to give advice to the king, and to acquaint him with the needs of the people. The Petition of Right, to which he had recently given his assent, he utterly disregarded. He descended to a puerile exercise of authority. His proclamations forbade the country people to come up to the metropolis, commanded all the shops in Cheapside, except those of the goldsmiths, to be shut, and prohibited the building of more houses in London, unless special leave (to be well paid for) were first obtained. But the great necessity was to procure money. The Council of the North was directed to compound with recusants. Monopolies were granted to companies in defiance of the spirit of the law. Neglect of the knight-hood which was no longer an honour was punished by a fine, which was often extremely severe. Pretensions to forest-lands, which prescription had long made unjust, were revived. And, lastly, the famous ship-money was levied. Besides, Charles must also be held personally responsible for other tyranny than that which was executed at his direct command. During these years Strafford was

maturing his policy of "Thorough," by which England was to be made subject to a standing army; and if Charles did not carry out this scheme as far as might have been possible, it was not because it was too bad, but only because it was too great for him. Though he had no love for its inventor he showed his respect for his absolute policy by making him president of the Council of the North, and sending him to govern Ireland with an iron sternness, which, though it certainly added to the prosperity of some parts of the island, as certainly helped to arouse in others the feeling which resulted in the horrors of the Irish massacre. He allowed the Star Chamber to sentence a clergyman to perpetual imprisonment, mutilation, and whipping for a libel against the bishops, and to reduce a gentleman to poverty for merely sneering at the badge of a nobleman. He sanctioned the inquisitorial Court of High Commission. He supported Land's oppression of the Puritans, his inculcation of celibacy among the clergy, of auricular confession, of prayers for the dead, and of the doctrine of purgatory, and he advanced men like Montagu, whom he knew to be desirous of a reunion of the English Church with Rome, confirming by all this the suspicions which the disclosures of Bristol had awakened.

At length, on his own sole authority, he commanded Scotland to receive a liturgy and a book of canons. The fatal results of this act belong to the history of Scotland. Unable to meet the Scottish army with a sufficient force, Charles summoned the Short Parliament; but as it refused to vote supplies till it made inquiry into the causes of the imprisonment of Eliot and his two companions, into ship-money, and other matters of that kind, it was speedily dissolved. A great council of the peers would not act alone; and in November 1640 he was compelled to summon the Long Parliament. The Commons were now happy in a leader magnificently fitted for the times. His fiery energy was repressed, not quenched, by the ripeness of his age; his courage and determination were too firm to be shaken; his respect for law and order was deep and strong; but deeper still and stronger were his love of liberty, and his resolve that nothing should serve as a bulwark against despotism. With the sagacity of the true statesman, Pym struck the first blow at the strongest pillar of the hateful structure. He exhibited articles of impeachment against the earl of Strafford. The impeachment was allowed to drop (against his wish), but it was only in favour of a bill of attainder. The preachers preached and the mob yelled against the great delinquent. The king went in person to the House of Lords, and tried to buy him off by promising never to employ him again; and then listened to a scheme, hatched by certain hot-headed officers and some of the fiercer of the courtiers, to bring up the army of the north and overawe the Parliament. But his entreaty was voted irregular; the plot was discovered, and the earl was condemned to death. Charles's weakness was now fatal to himself. A few months later the splendid ability of Strafford would have been invaluable to him. But he had no affection for the stern, haughty "dark earl," and, when the Lords refused his humiliating request that they would suggest to the Commons some milder punishment, he sacrificed his greatest servant. At the same time, Charles, who never knew the true place for firmness, yielded on another fatal point by confirming a bill, according to which the Parliament then sitting was not to be dissolved without its own consent. Before the triumphant course of the Commons everything had now to give way. The Triennial Bill was passed, ship-money, the Star Chamber, the High Commission, the Council of the North, the Council of Wales, the Council of Lancaster and Cheshire, the whole system of illegal exaction and injustice, were swept away. The religious passion of the

Houses manifested itself in an impeachment of Laud, and a proposal to abolish Episcopacy.

Charles once more resorted to the crooked policy which he usually employed in extremity. He visited Edinburgh, attended the Presbyterian worship, and loaded Argyll, Hamilton, and the other Presbyterian leaders with marks of favour, while all the time he was intriguing with the earl of Montrose, Argyll's open enemy. There was a darker suspicion at the time that an attempt, known as the "Incident," had been made by Montrose, with the king's knowledge, to assassinate Argyll; but this worse treachery is by no means proved. At this moment, while men's minds were full of excitement and apprehension, a massacre of thousands of Protestants took place in Ireland. It was known that O'Neale, the leader of the butchery, professed to have the king's written warrant and the ardent support of the queen; and many believed the hideous charge. They would have been more strongly convinced had they seen the letter in which his majesty coldly remarked that he trusted this trouble in Ireland would help to cure the folly at home. Other plots were also being discovered, of which men more naturally ascribed some knowledge to the king. Pym's life was in constant danger. An attempt was made to convey plague infection to him in a letter, and a gentleman was stabbed by mistake for him in Westminster Hall.

But Pym and the Parliament yielded not one step. On the 1st December 1641 the Grand Remonstrance was presented to the king, who received the committee which presented it in the highest spirits. He had returned from Scotland but a few days before, had been entertained at a great banquet by the Lord Mayor, and had made up his mind to show the Parliament that he was not to be trifled with. He had already appointed Colonel Lunsford, a disreputable scapegrace, to the command of the Tower. He now replaced the guard, which had protected Parliament since the news of the Army Plot, by a company under the earl of Dorset, who did not pass his first day of duty without firing on the people. Mobs far from orderly began to assemble round Westminster Hall, and a petition against the bishops was presented to the Commons. The bishops themselves were mobbed on their way to the House, and when they protested against the legality of what should be done in their absence, were summarily silenced by an impeachment. The excitement in the city grew dangerously intense, and Charles fanned the flame by accepting a company of armed soldier-adventurers as guard, and allowing them to quarrel with the unarmed crowd.

It was on the 3d of January 1642 that the final breach was made. Pym was not to be gained over, for only a few days before he had refused office. The king now practically declared war against the Parliament. How far he acted alone is disputed; but Clarendon is very likely right in saying that he was goaded on by the queen, who had retained from the political theory in which she had been educated some very lofty notions about the rights of kings and the duties of parliaments. On the morning of the 3d, he commanded Attorney-General Herbert to impeach Lord Kimbolton (against whom, however, the matter was not pressed), Pym, Hampden, Haslerig, Hollis, and Strode on a charge of high treason, founded upon their parliamentary conduct. The rooms, drawers, and trunks of the five members were illegally sealed at the king's command, and the king's sergeant-at-arms was illegally sent to demand their persons. The Commons behaved with the greatest dignity. The sergeant was commanded to show his respect for the House by laying aside his mace, and four members, of whom two were privy-councillors, were sent with a message to the king that the House would give him an answer as speedily as the greatness of the business would

allow, and that the members should meet any legal charge against them. But Charles had determined to crush the Parliament by force, and to make it for ever subservient to the Crown. He sent orders to the lord mayor that the guard sought by the Parliament should be employed to disperse all crowds, and to "shoot with bullets" all who resisted. On the morning of the 4th, at the head of his attendants, his pensioners, and the Whitehall guard, armed with partisans, swords, and pistols, to the number of three or four hundred men, he entered the House of Commons, and demanded the persons of the five members, declaring that treason has no privilege. But, with the formal consent of the House, they had taken refuge in the city; to the king's demands the sole reply was that given by the speaker, bravely, though tremblingly, and on his knees, that he could speak only as he was commanded by the House; and Charles was obliged to retire with undignified threats upon his lips. The consequence of this act was the most terrible excitement. Some members of the Commons cried "Privilege" in the very presence of his majesty. In London the shops were shut; there was a report that the cavaliers, with the king at their head, were about to fire the city, and it became known that a seizure of the arms of the citizens was contemplated. When the king visited the city next day, in the streets and in the court-room of the common council, he was met by cries of "Privilege of Parliament!" The panic still grew; the streets were thronged with almost frenzied crowds; the train bands were collected. Other crowds poured in from the country, one with a petition signed by thousands for the protection of Pym, another, from Buckinghamshire, eager to live and die with Hampden, to serve the Commons, respectfully to petition the king. The very sailors in the river caught the enthusiasm, and offered their assistance. And the House of Commons, declaring itself no longer safe at Westminster, adjourned first to Guildhall and then to Grocers' Hall. On the 10th Charles, seeing that the true magnitude of his attempt had been understood, and that he was met with his own weapons, retired in alarm to Hampton Court. On the following morning the five members returned to their seats in triumph, amid salutes from the river, the shouts of the crowd, and a parade of the train bands.

The Parliament retaliated the king's attack by passing a bill assuming the command of the militia, and appointing the lieutenants of counties. But the king on his journey from Dover, where the queen had embarked with the crown jewels, had met with so many expressions of loyalty that he refused his consent. He requested, however, that all requirements should be drawn up in one document, and submitted to him. Accordingly, in June 1642, Parliament presented "The Nineteen Propositions." They were such as would have entirely altered the constitution. Constitutional concessions could no longer avail the king; fifteen years of unconstitutional rule had made that impossible. He had striven to obtain the tyranny; he had appealed to force; and the Civil War had already begun with the Westminster tumults. On the 22d August 1642, it was formally commenced by the erection of the royal standard at Nottingham. At first success was on the side of the king, and the Parliament suffered so severely in the west that they began to discuss terms of peace, while several defections to the royalist party took place. But Charles was too highly elated; having summoned a parliament of his own at Oxford, he declared that which met at Westminster to be none; and when the earls of Holland, Bristol, and Clare came over to his party, he treated them with so much neglect and insult that after three months they turned back, and no others risked the treatment they had received. But as the troops of the Parliament became accustomed to the use of arms, and its officers to the tactics of war, the inferiority of the royalists

became apparent. In the beginning of 1645 the Parliament was in a position to demand, in the treaty of Uxbridge, that Presbyterianism should be established, and that it should have the command of the army and navy and the direction of the war with Ireland.

In the same year, after the decisive victory at Naseby, the king's cabinet, containing a number of letters which proved that he was promising toleration to the Catholics and seeking aid from several foreign powers, fell into the hands of the Parliament, and the letters were published. Soon after a still more important discovery was made,—that of a treaty entered into, by means of the earl of Glamorgan, with the Irish Catholics, whose aid was to be bought at the price of great religious concessions. Charles denied all knowledge of the affair, and Glamorgan was imprisoned for a short time; but subsequent evidence gives strong reason for believing that he was deeply implicated in the matter. Owing to the anti-popish bigotry which they offended, and the insincerity which they manifested, these disclosures were extremely damaging to the king.

In May of the next year Charles had fled to the Scots at Newark; and in January 1647 he was delivered by them into the hands of the English Parliament, who placed him in Holmby House, six miles from Northampton. Terms similar to those offered at Uxbridge were again tendered at Newcastle; but Charles, being sincerely attached to Episcopacy, was most unwilling to yield concerning church affairs, and, holding himself necessary to any settlement, believed that he had only to insist upon more favourable offers. In June the army took possession of his person, and finally brought him to his palace at Hampton Court. He was treated with respect and kindness; Cromwell and Ireton sought to bring about a secure peace; and the latter, on behalf of the Agitators or Adjutors, who formed the parliament of the army, drew up most favourable terms. But unable to see that the army was now supreme, and hoping, contrary to his whole experience, to obtain something more from the Parliament or the Scots, with whom he was treating, Charles haughtily broke with the officers, and scornfully refused their offers. To many it was now apparent that it was vain to hope for a settlement by means of compromise.

From this moment the ascendancy was taken by a party of enthusiasts, who held that a crown should not excuse the crime of treason against the country, and sternly called for justice on the grand delinquent. Fearing assassination, Charles fled to the Isle of Wight, where, however, he was captured. But trusting in the Scots, who now prepared to protect him by force, he still rejected the offers of the Parliament, which were again tendered to him at Carisbrook and at Newport. At length the army impatiently seized him once more, removed him to Hurst Castle, and thence to Windsor and St James's, purged the Parliament by excluding some hundred and forty members, and resolved to bring him to trial. On the 1st of January 1649, though the Peers adjourned refusing to consider the question, the Commons voted the appointment of a High Court of Justice "to the end no chief officer or magistrate might presume for the future to contrive the enslaving and destruction of the nation with impunity." One hundred and thirty-two commissioners were elected, of whom about half took part in the trial. Bradshaw was elected Lord President, and Cook solicitor against the king. On the 20th, the 22d, and the 23d, Charles was brought before this court; but with a calm and admirable dignity, due to a sincere belief in his own pretension, he proudly refused to acknowledge the court, declaring that obedience to kings is commanded by Scripture, that by the law the king can do no wrong, that the Commons have no authority of themselves to erect a court of judicature, and that they had

not received such authority from the people, whose power to confer it he, besides, declined to admit. On the 26th the court went through the form of listening to evidence that he had appeared in arms against the Parliament, which was declared to represent the nation. On the 27th Bradshaw pronounced sentence of death against Charles Stuart, as a tyrant, a murderer, and a traitor to his country; and on the afternoon of the 30th of January 1649, Charles was beheaded in front of the Banqueting House at Whitehall. His body was conveyed to Windsor, and on the 8th of February was buried in St George's Chapel without any service.

In person and in demeanour Charles presented a most favourable contrast to his ungainly, babbling father. A somewhat painful stammer was his only physical defect. His manner, also, was grave and reserved; his scrupulous observance of the ordinances of religion was accompanied by strict decorum of conduct; and he possessed considerable taste for literature and art. Yet of almost all the essential kingly qualities he was utterly destitute. He had, indeed, a strong sense of personal and royal dignity, but this very feeling was fatal to him. It rendered intolerable the least limitation of the prerogative which he believed to be his divinely-appointed birthright; and thus it placed him in obstinate opposition to the strongest tendency of his time,—that tendency which had already resulted in the Reformation, and which now manifested itself in the development of Puritanism and the growth of the English constitution. Nor did he possess the qualities which might have given him a chance of success in the contest. Affectionate toward his intimate friends to a degree of weakness which often arouses contempt, he had no magnanimity for an enemy, nor even fidelity to a servant, however great, who did not awaken his fondness. In political sagacity he was utterly wanting; and so completely did he identify political skill with duplicity that, in public matters, he could never be trusted, and compromise with him was impossible.

About the time of Charles's death several works appeared purporting to be by his hand. Of these the chief is the *Eikon Basilike: The Portraiture of his Sacred Majesty in his solitude and sufferings*. After the Restoration Bishop Gauden declared himself its author, and his claim was not disputed either by Clarendon or by Charles II., who, on the contrary, gave him ecclesiastical preferments. The controversy as to its authorship has left little doubt that it is a forgery. A collection of the works was published at the Hague in 1651, under the title of *Reliquiæ Sacre Carolinæ: The works of that Great Monarch and glorious Martyr, King Charles I.*

The chief contemporary authorities for the history of this reign are:—Rushworth, a barrister, and a member of the Long Parliament, who gives an account of the proceedings of the Parliament from 1645 to 1649, and also relates the trial of Strafford; Whitelocke, a moderate Parliamentarian, whose *Memorials* extend from the accession of Charles to the Restoration; Sir Ralph Verney and Sir Symonds D'Ewes, members of the Long Parliament; and May, author of the *History of the Long Parliament*. The *Hordwicke and Clarendon State Papers*; the recently published *Calendars of State Papers*; Carte's *History*, *Irish Massacre set in a clear light*, and *Life of Ormond*; Laud's *Diary*; Clarendon's *History of the Great Rebellion*, the work of a royalist partisan, whose great talents did not include political insight; and *The Letters and Speeches of Oliver Cromwell*, by Thomas Carlyle, also contain original information. As it deserves, this period has been more frequently treated by modern historians than any other in English history. In 1822 appeared Brodie's careful *History of the British Empire from the Accession of Charles I. to the Restoration*; in 1824–25 Godwin's republican *History of the Commonwealth*; in 1830 Isaac Disraeli's *Commentaries on the Reign of Charles I.* See also Hallam's *Constitutional History*; Forster's *Sir John Eliot, The Grand Remonstrance, The Imprachment of the Five Members, and Statesmen of the Commonwealth*; S. R. Gardiner's *Prince Charles and the Spanish Marriage*; Sanford's *Illustrations of the Great Rebellion*; Burton's *History of Scotland*. Especially on account of the analogy of this portion of English history with the French Revolution, it has been carefully studied by several French historians, among whom the most important is Guizot, who has published a *Histoire de la Révolution d'Angleterre*, and a *Histoire d'Oliver Cromwell*. It has also been treated in German by Dahlmann. See ENGLAND. (T. M. W.)

CHARLES II. (1630–1685), king of England, born in 1630, though the second son of Charles I., was Prince of Wales from his birth. In the earlier and more important campaigns of the Civil War he held a nominal command in the west, but he was too young to take any real part in the conflict. After the battle of Naseby he passed by way of Seilly and Jersey to join his mother at St Germain. Till 1649 he spent his time either at Paris or at the Hague, without interfering in public affairs, except when he attempted to save his father's life by forwarding a signed *carte blanche* to the Parliament to be filled up with any terms which they would accept as the price of his safety. On the execution of Charles I., he immediately assumed the title of king. The Scotch Government offered to place him on the throne by force, and sent a deputation to the Hague. For a time Charles protracted the negotiations, meanwhile urging Montrose to make him independent of the Presbyterians. But when the rising was crushed, and Montrose himself executed, he accepted their invitation. In June 1650 he landed in Scotland; and he was crowned at Scone on the 1st January 1651. But as he had been obliged to sign the Covenant, and conform to the austere manners of the Covenanters, he soon began to feel the price of their assistance intolerably heavy. The secret efforts which, during the whole time he was treating with the Presbyterians, he had been making to bring together a sufficient force of Highlanders proved unsuccessful; and, on the defeat of Leslie at Dunbar, he was glad to march south, with the hope of arousing the loyalty of the English. The appeal failed; and the royalist forces were again routed by Cromwell at Worcester (1651). Thanks to his own great coolness and address, and the fidelity of those in whom he confided, Charles contrived to reach France. Here he remained till 1654, when, having received a pension from the French king, he retired to Cologne. Thence he removed to Bruges, where he principally resided till the death of Cromwell. For the most part, notwithstanding the smallness of his means and the wretchedness of his circumstances, he passed his time in careless dissipation, surrounded by a little court in which the few old cavaliers, like Clarendon, who maintained the dignified manners which had adorned the court of Charles I., were lost in a crowd of gay young libertines and sprightly women of disreputable character. His applications for assistance to France and Rome were all unheeded; and he was equally unsuccessful in his attempts to contract an advantageous marriage. At length, through the contrivance of General Monk, but still more through the open and enthusiastic wish of a large portion of the people, he was recalled to England; his conciliatory declaration from Breda was well received; and he entered London amid sincere public rejoicings on his thirtieth birthday, May 29, 1660.

Charles's course was at first attended by no difficulty. The loyalty of the Convention summoned by Monk was sufficient for the time. It sympathized in the one desire for vengeance in which he was earnest; it was resolved on the punishment of the regicides. Thirteen were executed, some in direct opposition to the apparent intention of the king's declaration of oblivion; the bodies of Cromwell and Ireton were hung in chains; and even the coffin which contained the ashes of Blake was cast out of Westminster Abbey, and thrown into a common churchyard. And, finally, though some of the measures of the Convention prove that it had not lost all the spirit of the Long Parliament which preceded it, it showed its enthusiastic loyalty in a manner very agreeable to Charles, viz., by granting him the dangerous gift of £1,200,000 a year for life. But if the Convention was sufficiently loyal, the royalism of the first regular Parliament of the reign was extravagant. It insisted on the prerogative of the sovereign, and abased itself before

him. At his express request it repealed the Triennial Act; and it allowed him to declare that he would not be forced by that Act to summon frequent parliaments, if he believed that they would be disadvantageous to the Crown. It showed much reluctance to confirm the Act of Indemnity. It assisted him to complete his revenge by the sacrifice of Vane and Lambert, whom he had pledged his word to spare. But its royalism was equalled by its attachment to the Church of England; and thus commenced its opposition to the sovereign it professed to worship. Charles desired to tolerate the Catholics, and accordingly issued a General Declaration of Indulgence. Its illegality, however, raised so much opposition, even among the Protestant dissenters whom it benefited, that he prudently recalled it, and even published a proclamation banishing all Roman Catholic priests.

It was, indeed, the Protestant temper of the nation which was the most powerful influence against which Charles's policy had to contend. Fortunately for himself he was able to estimate its strength. Himself a Roman Catholic, he made several attempts to grant toleration to his co-religionists; but he always gave way when the anti-popish passion seized the people. Twice he yielded to a degree which more than any other of his acts displays the utter selfishness of his character. In order to blind the people, and prepare the way for the trial of Shaftesbury, he sacrificed the Catholic Archbishop Plunkett, the accusation against whom was supported only by the most worthless witnesses. But the basest compliance of which he was guilty was in the case of the pretended Popish plot. He did nothing to allay the popular frenzy; he allowed Oates to be handsomely pensioned, and located at Whitehall; the only case in which he is reported to have interfered was that of his wife, who was not, indeed, seriously threatened; and he calmly signed the death-warrants of men whom he must have regarded as martyrs.

It is remarkable that the matter in regard to which Charles most firmly withstood opposition was one in which he was not personally concerned—the exclusion of his brother, the duke of York, from the succession. This is the more remarkable as there is good reason to believe that his affection was much stronger for the duke of Monmouth, his own son by Lucy Walters. He treated him like a legitimate prince, and permitted him to wear the royal arms without the bar sinister, and to make progresses through the kingdom, on which he was received as if he had been heir to the throne. Towards the end of his life (in 1682), however, he was so seriously displeased with one of these progresses as to banish the duke to Holland; possibly the licence which Monmouth assumed was only permitted by the king; and we may, perhaps, give him credit for having all along unselfishly desired that his brother and a Catholic king should succeed him.

Concerning the character of Charles historians are in general agreement. His selfishness, which was of the sensual, indolent, good-humoured type, was such that he was incapable of understanding motives different from his own. His chief aim was to support, without trouble or censure, his own gay and dissipated life, and his troop of mistresses. This was no easy matter; his mistresses were numerous, and he was fond of indulging them to the utmost of his power. One was raised to the rank of duchess of Portsmouth, another to that of duchess of Cleveland; six of the sons they brought him were created dukes;¹ and means were supplied to maintain their lofty dignity. They occupied a recognized position at court; and the queen was obliged to humiliate herself, and to treat them without

scorn, and even with familiarity. In short, the court of Charles was the most scandalous which England has seen. Yet, being affable and witty, and free from all vindictiveness, Charles enjoyed a good deal of popularity, if nothing of respect.

In 1662 Charles married Catherine, princess of Portugal, who brought him half a million of money, Bombay, and the fortress of Tangiers. He died, probably of apoplexy, without legitimate issue—for there is no evidence to support the popular belief in the legitimacy of Monmouth—on the 6th February 1685, after receiving extreme unction from a Roman Catholic priest named Huddleston.

Throughout his whole reign, and especially by his secret negotiations with Louis XIV. of France, whose pensioner he was not ashamed to be, Charles exerted a powerful and harmful influence on English politics; but his political action is matter of history, and is treated elsewhere.

See the *Diaries* of Pepys and Evelyn; *The Mémoires de Gramont*; the *English histories* of Burnet, Hallam, and Macanlay; *Kennet's Register*; and *The Calendar of State Papers of the Reign of Charles II.*, edited by Mary Anne Everett Green (1860-66).

CHARLES I., the Bald (823-877), king of France and emperor of the Romans, was son of Louis le Debonnaire, by his second wife Judith. To furnish him with a kingdom, his father deprived his elder brothers of some of the territory he had previously assigned to them, and war ensued, at the end of which, after many failures and successes, Charles was left in possession of a great kingdom in the west of the empire. On the death of his father in 840, Charles sought to succeed as emperor, and allied himself with his brother, Louis the German. In 841, in a battle at Fontenai, remarkable for the number of the slain and the fierceness with which it was contested, Charles's rival and eldest brother Lothaire was defeated; but such had been the loss even of the victor that it was impossible to follow up the victory. The alliance between Louis and Charles was renewed, the former taking his oath in words which form one of the earliest specimens of the Romance language; and in 843 the treaty of Verdun confirmed to Charles the possession of his kingdom, which comprised France to the west of the Meuse, Saône, and Rhone, and Spain from the Ebro to the Pyrenees. The weakness of Charles's government was, however, extreme. The Normans, sailing up the rivers in small companies of a few hundreds, pillaged the country almost without resistance; at length in 858 the people in despair, calling in the aid of his brother Louis, drove the king from the country for a time. Charles was entirely under the control of the bishops, and his submission did not go without reward; in 875 he was crowned emperor by the Pope. But Louis attacked him with great success; and his power was far from stable when, having been summoned into Italy by the Pope against the Saracens, he died in 877 near Mont Cenis. The last and perhaps most important act of his reign was the decree of Chiersi, by which the tenure of the counties was made hereditary.

CHARLES II., the Fat (832-888), king of France and emperor of the Romans, was the third son of Louis the German. Swabia he inherited from his father; the death of his brother Carloman of Bavaria made him king of Italy in 880; in 881 he was crowned emperor; the death of another brother, Louis of Saxony, gave him possession of all Germany in 882; and that of Carloman the French king in 885 left him the kingdom of France. Thus, by no effort of his own, he became sovereign of all the dominions of Charlemagne. But he was soon found to be utterly incapable of ruling. He was, in fact, given up to pleasure, especially to the pleasures of the table. When the Northmen besieged Paris, he made not the least attempt to repulse them by means of the vast army which

he led against them, but bought them off with disgraceful presents. He was, therefore, justly rejected by the people, in 887 he was deposed at Tribur; and he died in the cloister during the following year.

CHARLES III., the Simple (879-929), king of France, was a posthumous son of Louis the Stammerer. On the deposition of Charles the Fat in 887, he was excluded from the throne by his youth; but during the reign of Eudes, who had succeeded Charles, he obtained the alliance of the emperor, and forced the former to cede Neustria. In 898, by the death of his rival he obtained possession of the whole kingdom. His most important act was the treaty which he made with the Normans in 911. They were baptized; the territory which was afterwards known as the duchy of Normandy was ceded to them; and their chief, Rollo, married the sister of the king, and was created duke. In 922 the barons, jealous of the growth of the royal authority, rebelled and elected Robert, brother of the late king, in place of Charles. Robert was killed in the battle of Soissons by Charles's own hand, but the victory remained with his party, who elected Raoul, duke of Burgundy, king. In his extremity Charles trusted himself to Herbert, count of Vermandois, who deceived him, and threw him into confinement. Released by his old enemy, Raoul, he died at Peronne in 929.

CHARLES IV., the Fair (1294-1328), king of France and Navarre, was the third son of Philip the Fair. In 1322 he succeeded his brother Philip V. on the throne of France and Navarre. The chief aim of his domestic policy was to free the country from the Lombards and from the exactions of the barons and the judges; and he did something to improve the condition of the Jews. He assisted his sister Isabella in her contest with her husband, Edward II. of England. In 1325, being supported by the Pope, Charles sought the imperial crown, but without the least success.

CHARLES V. (1337-1380), king of France, born in 1337, was the son of John II. His physical weakness, precluding him from the usual ambitions of his rank, led him to cultivate the taste for literature and the political ability which gained for him the title of "the Wise." From the age of nineteen to that of twenty-three, during the exile of his father, a period of great disturbance and difficulty, he ruled as lieutenant of the kingdom. The first States-General which he summoned, led by Stephen Mareel, president of the tiers-état, and Robert le Coq, president of the clergy, refused to raise levies or subsidies, and demanded, first, the trial before judges nominated by themselves of the ministers of justice and of finance, whom they accused of corruption; secondly, the establishment of a council chosen from the three chambers to be consulted in all cases by the dauphin; and lastly, the release of the king of Navarre. Next year (1357) they were equally determined; they forced the dauphin to give his assent to an ordinance which greatly extended the authority of the States, and the commission appointed to carry it out ruled for some time with dictatorial power. The authority of Mareel also was such that he was bold enough to enter the palace of the dauphin, and slay two of his chief officers,—the marshals of Champagne and Normandy. At the same time another enemy, Charles, the king of Navarre, was enjoying unbounded popularity among the people of Paris, and maintaining their cause. France, indeed, seemed ripe for revolution, for its condition was wretched in the extreme. The heartless ravages of the English, of the free companies, and of the French nobles themselves had laid waste the country, and maddened the peasantry till, under the name of *La Jacquerie*, they burst into hideous revolts, in which they committed the most brutal outrages against the hated nobility. But after a few months, by the assass-

situation of Marcel, and the support of the nobles and of the provincial States, Charles regained the supremacy. When he again appealed to the States-General, in order to obtain the rejection of the ruinous treaty of London, which John had signed in his eagerness to procure his own release, he also received from them troops and money to carry on the war in Picardy. But he never again convoked them, except on one occasion (in 1369), when they are said to have proved extremely submissive. Ever after he had recourse to assemblies of notables, or to the provincial States, which never ventured to offer him serious opposition.

From 1360 to 1364 John, ransomed by the treaty of Breigny, ruled in person; but in the latter year, to save his honour, he returned to London, and in April he died there, leaving the crown to Charles.

Charles at once set himself vigorously to the task of binding up the wounds of the kingdom, and preparing to expel the English. He employed Duguesclin, an able soldier of Brittany, to lead 30,000 men of the free companies into Spain, and to set Henry of Transtamare upon the throne. Thus he not only freed the country from a grievous scourge, but also obtained the friendship of the Spanish king. He had already made alliances with the king of Castile, with the count of Flanders, with Scotland, and even with Charles of Navarre; and after having carefully fortified the principal towns, he provoked a renewal of the war with England. The wise policy on which he had resolved was carried out with great firmness. Pitched battles were avoided, and the enemy, being repulsed by the towns, had nothing left but to ravage the country, with the result of deepening the hatred of the people. The Bretons were gained over, and soon all the land to the north of the Garonne ceased to belong to the English (1373). In 1380 the conquest of Guienne by the French left them only Bayonne, Bordeaux, Brest, and Calais.

At the same time Charles crushed his other great enemy, the king of Navarre. After accusing him of various plots against himself and other members of the royal family, he took his two sons as hostages, executed two of his ministers, and raised up enemies against him who seized great part of his territory, and forced him to give up twenty places as security for peace.

But Charles's last aggressive attempt was not equally successful. He summoned the duke of Brittany before him, and when he failed to appear, declared his dukedom confiscated to the crown. The result, however, was that the people recalled the duke, who had previously been banished, and formed an alliance with England. While affairs were in this condition Charles died at Vincennes, on the 16th September 1380.

His reign had left many important results. The country had been freed for a time—though, unfortunately, only for a time—from its two great scourges, the free companies and the English. The residence of a pope at Avignon under the influence of the king tended to make the Gallican Church more independent. The privileges of the nobility were somewhat invaded by Charles's favour to the burgesses of Paris. Something was done to increase the purity of the administration of justice, and the parliament of Paris was allowed to become self-elective,—a reform which, however, was only temporary, a retrogressive change being made under Charles VII. On the other hand, the States-General were silenced; the personal power of the king was increased; and the weight of taxes, often from their nature peculiarly oppressive, was greatly multiplied, for, notwithstanding the grievous war expenses, Charles set no limit to the free indulgence of his tastes. He left several costly specimens of the expensive art of architecture, including the splendid palace of Saint Paul and the

strong walls of the Bastille; and he distinguished himself still more honourably by founding the royal library at Paris.

See Froissart, *Roy's Histoire de Charles V.* (1849), and *The Chronicle of St Denis*.

CHARLES VI. (1368–1422), king of France, was the son of Charles V., whom he succeeded in 1380, at the age of twelve. The treasure left him by his father was at once seized by his four uncles, the dukes of Berry, Burgundy, Anjou, and Bourbon, whose tyranny and rapacity aroused a general rebellion throughout France. It gained the supremacy in Paris (where the insurgents, from the weapon with which they armed themselves, took the name of *Maillotins*), in Rouen, and in many other French towns, and also in the Flemish cities, of which the foremost was Ghent, now led by Philip van Artevelde. At first the union of the popular parties in the various towns was successful against the nobility, but in 1382 the latter won a great victory at Roosebeke, in which Artevelde was killed, and after which many of the rebels were punished by death or by heavy fines. In 1385 immense and costly preparations were made for an invasion of England, in which the king was to take part in person, but on account of various obstacles, over which he had not sufficient resolution to triumph, nothing was done. In 1388, with the advice and support of the cardinal of Laon, Charles, who had six years before reached the age fixed for his majority by his father, threw off the control of his uncles, the dukes of Berry and Burgundy. But in 1392, on his march against the duke of Brittany, who had seized and then attempted to assassinate the constable, De Clisson, the appearance of a rough-looking man, who declared that the king was betrayed, so affected him that, in a fit of madness, he killed four of his attendants, and was for some time after insane. During the next year another accident, by which he was nearly burnt to death, brought on a second fit, from which he never completely recovered. By these unfortunate events a field was opened for the ambition of the dukes of Burgundy and Orleans. The latter first obtained the government; but the former, John Sans Peur, as champion of the people of Paris, gradually became so powerful that, in 1407, he ventured to assassinate his rival and allow the mob to massacre his adherents. But a confederacy was formed against him, the duke of Orleans who succeeded his victim being joined by the dukes of Berry, Bourbon, and Brittany, and the powerful and able count of Armagnac. The Parisians opened their gates to the Armagnacs (as the party was now called), but they in turn treated Paris as if it had been a hostile city conquered by force. In 1415 Henry V. of England, the fulfilment of the treaty of Breigny being refused, landed in France, and gained the victory of Agincourt. In 1418 the gates of Paris were opened to the duke of Burgundy, and another massacre of the Armagnacs took place. Famine and plague carried off thousands of others. Charles died, deprived of almost every sign of royal dignity, in 1422.

See *The Chronicle of St Denis*, Monstrelet, Juvénal des Ursins, Le Laboureur, De Choisy, Saint-Remy.

CHARLES VII. (1403–1461), king of France, the son of Charles VI., was betrothed at ten to Mary of Anjou, daughter of Louis, king of Sicily, whom he married nine years after. He became dauphin at the age of thirteen; and while only fourteen, on account of the insanity of his father, he held the position of lord-lieutenant of the kingdom. At first the strong hand of Bernard of Armagnac, the constable, guided the government; but the triumph of the Armagnacs, crowned by the murder of John of Burgundy in the very presence of the dauphin, brought the most serious trouble upon France. Aided by the Burgundians,

the English soon gained a mastery so complete that in 1420 the treaty of Troyes conferred the succession upon their king, Henry V., who had married Catherine, the daughter of Charles VI. In August 1422, however, Henry died, and Charles VI. a few weeks after. Bedford became English regent of France; and the ability of his administration resisted all hostile attempts. The defeats of the French at Crevant (1423) and Verneuil (1424) were disastrous, and their successes were few and unimportant. It was plain that Charles, intent upon nothing but a round of frivolous dissipation, would never effect the independence of the country. Though he was capable of being roused to energy, the weakness of his character was conspicuous. He was dependent upon a succession of advisers, which included both the worst and the greatest men and women of his day. No king was ever cursed by more worthless favourites than Charles during his youth, and no French court was ever in a state of more miserable anarchy than that of the first years of his reign; but yet to none could the title of "Well-Served" have been more fitly applied, for none has borrowed more undeserved glory from the great men who surrounded him. Favourite at first rapidly followed favourite,—Tannequi Dûchatel, the lawyer Louvet, Pierre de Giac, the haughty Lecamus de Beaulieu, and La Trémouille.

But France was not entirely left to these selfish courtiers. A national spirit was rising, and she possessed many bold soldiers who were willing to fight her battles. The constable Richemont, though violent, and though he unfortunately laboured under a superstitious terror of heresy and sorcery, was honest and capable. Under him fought Dunois the bastard of Orleans, La Hire, Xaintrailles, Brézé, Jean and Gaspard Bureau, and the three brothers Chabannes. But the greatest impulse was given to the French arms by the noble country maiden, Joan of Arc, who, after placing the king firmly on the throne, received from him as reward nothing but jealousy and the most heartless desertion (see JOAN OF ARC). The benefit which she wrought for France did not end with her life. The English were still forced to give way. In 1435, by the treaty of Arras, Philip the Good of Burgundy broke with them, and joined the French; the death of Bedford in the same year left them no chance of rallying, and soon Paris received its rightful sovereign.

In the meantime a great change had come over the court and the king. Charles had fallen into better hands. A most beneficial influence has been ascribed to Yolande of Aragon, his mother-in-law, Isabel of Lorraine, his sister-in-law, and Agnes Sorel, his mistress. And, more important still, a great revolution had taken place in the royal council, a large part of which now consisted, not of nobles, but of commoners. The greatest of these was Jacques Cœur, who, having amassed a vast fortune by financial speculations and commerce, had become the *argentier* of the king, and gradually acquired power in all the branches of administration. Surrounded by men of energy and patriotism, Charles's facile nature reflected both these virtues, and he appeared in the battle-field among his troops. Normandy was recovered by Dunois and Richemont (1449); the English were driven out of Guienne; and in 1453 there remained to them nothing but the single fortress of Calais. Among the other important events that had meanwhile taken place may be mentioned the ratification in 1438 of the "Pragmatic Sanction," and extensive army reforms whereby both privates and officers became immediately dependent upon the sovereign.

In 1450 Agnes Sorel died. Soon after, and in connection with her death, occurred Charles's second great act of ingratitude. Jacques Cœur, by aid of whose abilities and money much of the success of the reign had been achieved,

was accused of intrigues with the dauphin, and charged with poisoning Agnes at his instigation. He cleared himself of these charges, but others were immediately substituted, which, so far as they were true, afford no excuse for Charles. He was condemned to death; and though his life was spared, his property was confiscated, and himself banished from the country (1453).

Towards the close of Charles's life his condition became even more scandalous and wretched than it had been in the troublous times of his youth. With the death of Agnes all show of dignity and decency was cast aside, and the king at length died, the miserable victim of his own faults. Bitter ill feeling had arisen between him and the dauphin; the latter had fled; his father's repeated entreaties could not induce him to return; and Charles, insane through his fear that his son would seek to get rid of him by means of poison, refused to eat, and on the 22d July 1461 died at Mehun of starvation.

During this reign there had taken place three events of the first importance to France,—the expulsion of the English and of the free companies, the establishment of a standing army, supported by a large permanent tax, and the enactment of the Pragmatic Sanction. Besides these, the university of Paris has been brought under the jurisdiction of the Parliament, and other reforms, such as the shortening of the legal processes, and the strict prohibition of all presents to members of the court, had been effected. In case of vacancies it was decreed that the Parliament should nominate two or three persons, from whom the king should select one. The Court of Aids was also instituted, to decide all cases connected with the levying of taxes; but its constitution was extremely faulty, as it gave to the same persons, viz., the treasurers, the power of extortion and of trying for extortion.

See Vallet de Viriville, *Charles VII. et son époque* (1862-5), and Clément, *Jacques Cœur et Charles VII.* (1873).

CHARLES VIII. (1470-1498), king of France, born in 1470, succeeded in 1483 to the power acquired by the astute policy of his father Louis XI. His sister, Anne of Beaujeu, though only twenty-two, by the firmness and craft which she inherited from her father, gained the supreme authority as regent. She was opposed by the duke of Orleans and Count Dunois, who were supported by the duke of Brittany and the emperor Maximilian; but Dunois was defeated in Guienne; and in the battle of St Aubin the duke of Orleans was routed and taken prisoner. One important internal reform took place under the government of Anne,—a change was made in the mode of election of the States-General. In the first place, members were no longer called as feudatories of the king, even barons and bishops appearing not by right of title but as representatives of the gentry and the clergy; and secondly, the right of voting for members of the tiers-état was given even to the peasantry. In 1490 Anne's authority came to an end, for the king released Orleans, and entered into the most familiar friendship with him, and also took Dunois as his chief adviser. Under his influence he broke off the contract of marriage with the daughter of Maximilian, and took as his wife Anne of Brittany, to whom Maximilian had been betrothed. In consequence a war broke out, in which England and Spain took part against France; but Henry VII. was bought off by a gift of money, and in the treaty of Senlis, Spain was persuaded to make peace by the surrender of Roussillon and Cerdagne, and Maximilian by the restoration of Franche-Comté and Artois.

Charles was now at liberty to attempt the realization of his dream of founding an Eastern empire. His father had purchased the claim of the House of Anjou to the throne of Naples, and he himself bought the title of Andrew

Palæologus, the nephew of the emperor of Constantinople. Having made a treaty with the Pope, Charles in 1495 entered Naples unresisted. But he showed no favour to the Neapolitan nobility, and gave all offices to his own soldiers. In consequence much discontent arose, and a league was formed against him by the Pope, the emperor, Spain, and Venice. With 5000 men he defeated at Fornova an army greatly outnumbering his own; but the victory merely enabled him to reach France. Naples soon fell into the hands of Ferdinand of Spain; and Charles died at Amboise, through an accident, at the age of twenty-eight, before he could carry out his intention of returning to Italy (1498).

CHARLES IX. (1550-1574), king of France, was the second son of Henry II. and Catherine de' Medici. At the age of ten he succeeded his brother Francis II. His mother became regent, and Anthony of Navarre lieutenant of the kingdom. During Charles's youth there was fierce and continual war between the Huguenots, under Condé and Coligny, and the duke of Guise and his adherents. In the second period of the contest Catherine opposed the former party; but in 1570 Charles, declaring himself convinced that conformity in religion is impossible, and avowedly acting on his own judgment and in opposition to his mother, brought about a reconciliation with the Huguenots. His sister was married to the young Huguenot king of Navarre, Charles protesting that their union should not be prevented even by the Pope. Admiral Coligny was received into familiar friendship, made one of the council, and treated as the chief adviser of the king, while on the attempt to assassinate him Charles expressed deep regret and an earnest intention to punish the crime. His sincerity in this course of conduct has been questioned; we are reminded that he was neither scrupulous nor merciful, and it is said that his restless and apparently open manner concealed a long-conceived and terrible treachery. According to another and more probable account, he was not acquainted with the plots of his mother till their fulfilment was almost at hand, and it was on the ground that the Huguenots were conspiring against the throne that he was prevailed upon not to interfere in preventing the massacre of St Bartholomew's day 1572. His consent was wrung from him, it is said, in an agony of passion, and the memory of the event tortured him till his death, which occurred at Vincennes only two years later. But there is no doubt that his consent was given, for next day he avowed the act, declaring that it had proved necessary in order to check a dangerous rebellion. Charles left a work on hunting, entitled *La Chasse Royale*, an edition of which, published in 1857, contains also several poems by him.

Contemporary accounts of this reign were published by Des Portes, Sainte-Foy, and Favier in 1574, the year of Charles's death, and by Varillas in 1584.

CHARLES X (1757-1836), king of France, a younger brother of Louis XVI., known before his accession as Charles Philippe, Count of Artois, was born in 1757. At the age of sixteen he married Maria Theresa of Savoy. His youth was passed in a course of scandalous dissipation; but for a short time he joined the French army at Gibraltar, and during the disturbances immediately prior to the Revolution he took a minor part in politics. In July 1789 he left France, and visited several of the European courts, in order to procure assistance for the royalist cause. On the execution of Louis XVI., he assumed the title of Monsieur, and in the campaign of 1792 he commanded a regiment of French gentlemen; but in February 1793 he retired to Russia, where he was warmly welcomed by Catherine. In August 1795 he led an expedition, fitted out by the English, to assist the revolt in La Vendée but he displayed no energy, and

effected nothing. Retiring after this to England, he resided for a time at Holyrood Palace, and afterwards with his brother Louis at Hartwell. In April 1814 he was cordially welcomed back to Paris by the Provisional Government. During the reign of his brother, Louis XVIII., he was the leader of the extreme royalist party, who aimed at bringing back the state of affairs which had existed before the Revolution; and on succeeding to the throne in September 1824 he continued to follow the same policy. His frequent appearances in public, and the dignity of his address, at first avoke considerable enthusiasm; but his popularity was brief. M. Villèle, who had already directed the government for some time, continued to be chief minister. A bill was passed by which a thousand millions of francs were devoted to recompense the losses of the emigrés (March 1825). The Jesuits were, it was believed, encouraged to return to France. Severe laws were made against sacrilege, death being assigned as the penalty for theft from consecrated ground, and profanation of the consecrated elements being regarded as a crime equal to parricide; and the censorship of the press, which he had abolished at his accession, was re-imposed. At length, in January 1828, Charles made a compromise by replacing the unpopular ministry of Villèle by a ministry headed by the Marquis of Martignac. But the change was temporary; soon after he called to the head of affairs Prince Polignac, a personal friend, whose views exactly coincided with his own, and the choice of whom consequently aroused the deepest dissatisfaction. But Charles refused to give way, and the address of the Chambers requesting the dismissal of the prince was answered with a dissolution. His foreign policy, meanwhile, was popular, for his troops gave assistance to Greece and conquered Algiers. But this could not save a king who so little understood the temper of his people. On the 25th June 1830 he issued ordinances, of which one forbade the publication of any periodical without Government permission, another dissolved the new House of Deputies which had not yet met, and a third placed the elections under the power of the prefects. This excited a spirit of resistance which spread rapidly through Paris; barricades were thrown up; the troops were repulsed; and in three days the revolution was completed, Charles meantime doing absolutely nothing. At length he recalled his edicts; and he afterwards resigned in favour of his grandson, the duke of Bordeaux. But all was now in vain. Louis Philippe was elected king; and Charles retreated from St Cloud to Trianon, from Trianon to Rambouillet, and finally returned to Holyrood, where he lived four years. He died at Görtz in 1836. The close of his life was spent in religious austerities, which were intended to atone for his former dissoluteness.

CHARLES I., emperor. See CHARLEMAGNE.

CHARLES II., emperor. See CHARLES I. of France.

CHARLES III., emperor. See CHARLES II. of France.

CHARLES IV. (1316-1378), emperor of the Romans, was the son of John of Luxembourg, king of Bohemia. As a child he spent five years at Paris, but at the age of twelve he returned to his father's court. While only sixteen he was appointed vicerey of Italy,—a post of the greatest difficulty, from which it was not long before he was obliged to retire. He next took part in the Carinthian war against the Emperor Louis of Bavaria, the great enemy of the Pope. In 1346, on the death of his father at Crécy, he became king of Bohemia; and in the same year he was elected emperor in place of Louis, through the influence of Pope Clement VI. But Charles only gained this dignity at the cost of many humiliating concessions, which made him appear the mere tool of the Pope and robbed him of the respect of the electors. On the death of Louis in the next year, they refused to recognize him, and chose first

Edward III. of England, then the Marquis of Meissen, and lastly, when both of these refused the honour, Count Günther of Schwarzburg. On the death of the last, however (an event which he was accused of having accelerated by poison), Charles, who had married Anne, daughter of the Elector Palatine, and given his own daughter, with Tyrol as dowry, to the duke of Austria, was unanimously elected. He devoted all his care to the aggrandizement of himself and his family; and the government of the empire was very negligently administered. In 1354 he visited Italy, and was crowned at Milan, Rome, and Ostia; but he received many indignities, being, for example, refused entrance to several cities, and only allowed to remain at Rome a single day. He was obliged to confirm the Viscontis in their usurpation; and he left the country, after amassing a large sum of money,—a mockery to both Guelf and Ghibelline. As third wife Charles took the daughter of the duke of Jauer, to whose dukedom he hoped thus to obtain the succession. He also added Brandenburg, Silesia, and Lower Lusatia to the possessions of the House of Luxembourg; and he obtained from the electors, by means of large bribes, the recognition of Wenceslas as his successor. He allowed the empire meanwhile to be overrun by banditti, and he only once took up arms. This was at the call of the Pope, to whom he was always submissive; but even on this occasion he allowed himself to be bought off by his adversaries, the tyrannous Viscontis. The only important measure which he effected was the publication of the Golden Bull (1356), which determined the method of election for the dignity of emperor. It decreed that the number of the electors should be seven:—three ecclesiastical, viz., those of Mayence, Cologne, and Trèves; and four secular, viz., the king of Bohemia, the Count Palatine, the duke of Saxony, and the margrave of Brandenburg. The king of the Romans, and future emperor, was to be elected by the majority in a meeting to be held at Frankfort. The Pope thus lost all influence over elections; and to escape his anger Charles granted him a title of all ecclesiastical incomes, together with some other concessions. Charles died at Prague in 1378, having immensely enriched the house of Luxembourg, but leaving the empire greatly the worse for his reign.

CHARLES V. (1500–1558), emperor, the ablest and most powerful monarch of the 16th century, was born at Ghent, February 24, 1500. He was the converging point and heir of four great royal lines, which had become united by a series of fortunate matrimonial alliances. His father was Philip of Austria, who being the son of the Emperor Maximilian and of Mary, only daughter and heiress of Charles the Bold, transmitted to him the possession of the Netherlands, and of the hereditary dominions of Austria, as well as a solid claim to the imperial crown of Germany at the next election. His mother was Joanna, second daughter, and finally heiress, of Ferdinand of Aragon and Isabella of Castile, joint rulers of Spain, who handed down to their grandson the united monarchy, increased by the conquest of Granada in 1492, by the addition of the two Sicilies in 1504, by the annexation of the southern part of Navarre in 1512, and by the discovery of the New World. Seldom, if ever, in the history of the world has any one been born to such vast possessions and to such weighty responsibilities. He fell heir to the Netherlands on the death of his father in 1506, to the crown of Spain and Naples on the death of his grandfather Ferdinand in 1516, and to the archdukedom of Austria on the death of his grandfather Maximilian in 1519. Before the future emperor was born, Columbus had been discover-

ing for him territories of unlimited extent and fabulous wealth beyond the pillars of Hercules. When he was only fifteen years of age the first European saw the Pacific Ocean; and while the crown of Charlemagne and Barbarossa was being placed on his head at Aix-la-Chapelle, Magellan was prosecuting the great voyage which was to result in the circumnavigation of the globe, and Cortes was engaged in the arduous conquest of Mexico. Ere he had been twenty years on the throne of Spain, Pizarro had completed the conquest of Peru. This was not all. It must be remembered that two at least of the countries he was destined to rule were approaching the very highest point of their intellectual, moral, and material development. The ingenious and energetic population of the Netherlands were carrying industry to a pitch till that time unexampled in the history of the world, while the vast wealth they accumulated could in the hands of a politic ruler become an almost exhaustless source of revenue. It was the heroic period in the history of Spain, the period of final victory over the Moors, and of the romantic conquest of a new world, when religious and military enthusiasm elevated the national character in such an extraordinary manner; in war, diplomacy, and government the pre-eminence of the Spaniards was acknowledged and dreaded. In fact, the material wealth of great countries and the genius necessary to form it and to guide it were available to an extent which has seldom been surpassed.

On to 1517, when he went to enter upon the government of Spain, Charles lived in the Netherlands. He was carefully educated, though his tastes attracted him more to the active exercises of the chase and of the tilting ground than to the dry and pedantic learning of the time. William of Croy, Lord of Chièvres, was appointed to superintend his education, while under him Adrian of Utrecht, afterwards Pope by the name of Adrian VI., was the teacher of the young prince. The latter was not able to inspire him with any love for the scholastic learning in which he excelled, while the former did not attempt to lay any constraint upon his natural bent. He took care, however, to instruct him in the knowledge more directly useful to a prince, in the study of history and the science of government, and especially sought to interest him in the practical direction of affairs. If we may judge from the result he was perfectly successful, as his pupil grew up to be a great adept in the arts of government, and to be the active and direct moving power in everything that transpired during his reign. Yet his character was late in developing. His excessive deference to his teachers and the undue place he gave them in the government rendered him very unpopular during his first visit to Spain (1517–19).

In 1519 the news arrived of the death of his grandfather Maximilian, and then of his own election to the imperial crown. The contest between him and Francis I. had excited universal attention in Europe. The crown had been first offered to Frederik the Wise, elector of Saxony, but that prince recommended Charles on the plea that the critical state of the empire, especially on account of the alarming progress of the Turks, required for it a powerful protector. And, indeed, now that Charles had attained to the highest position in Christendom, he found that the vast extent of an empire, consisting of nations geographically disconnected and brought under the same head, not through any real affinity, but by the accident of matrimonial alliances, had only increased the number of his rivals and the many-sided complexity of his duties. Between Charles's dominions in Spain and the Netherlands, holding the duchy of Burgundy, which Charles claimed by hereditary right, and the duchy of Milan, over which he was bound to assert the old imperial claims, angry because of the

Spanish conquest of Navarre, and chagrined by his defeat in the contest for the imperial crown, Francis ruled a compact and united kingdom, not capable certainly of matching the vast empire of Charles, yet not easily accessible to attack, and formidable on the battle-field. About the same time that Charles was crowned at Aix-la-Chapelle, the throne of Turkey was ascended by Soliman the Magnificent, who himself the heir of mighty conquests and of well-disciplined armies, carried the Ottoman empire to the very pinnacle of its power (1520-66); his progress through Hungary up to the walls of Vienna was marked by an ever-advancing line of fire and blood; his fleets commanded the Mediterranean, and threatened the coasts of Italy and Spain, while the corsairs of Tunis and Algiers, under the renowned Barbarossa, who was soon to acknowledge his allegiance, infested the seas, and, spreading terror all along the northern shores of the Mediterranean, carried thousands of Christians into slavery. The Pope was a doubtful and suspicious ally or an open enemy, as the interests or passions of the Holy See seemed to dictate, and Henry of England, aspiring to be the arbiter of Europe, pursued an equally capricious course of vacillation. In Spain itself the discontent of the commons broke into open revolt, while the haughty nobles required to be skilfully managed. Above all, on the very year of the coronation, Martin Luther had burned the papal bull which condemned him at the gate of Wittenberg. No one could yet foresee the extent of the chasm opened up in the Christian world by the heroic defiance thus hurled at its spiritual chief; but it soon became clear that the heart of Germany was with the Augustinian monk, and that many powerful influences, in the empire and out of it, religious, social, and national,—science, culture, patriotism, morality, and piety—were working towards the overthrow of priestly domination. On all sides, then, Charles had difficult work to do. In Italy and Navarre, and on the Flemish frontier, he had to make head against the armies of Francis; in Hungary and in the Mediterranean he had to arrest the progress of the Turks; he required to watch the wayward king of England and the crafty popes, to manage the haughty susceptibility of Spanish grandees and the boisterous independent spirit of the Flemish cities, to compose the religious troubles, and to stay the growing spirit of revolt against the old state of things.

From his coronation at Aix-la-Chapelle, Charles proceeded to the Diet of Worms, which opened on the 28th of January 1521. After a council of regency had been appointed, which under the presidency of his brother Ferdinand was to govern during the emperor's absence, and other business had been disposed of, the religious difficulty was taken up. Though political considerations always prevailed with Charles during his active career, he was a Catholic by conviction, and was by no means disposed to encourage the hopes entertained of him by the liberal party in Germany. Besides, the old traditions of the empire, in which he firmly believed, required that he should support the church. At the same time, the Reformation was too strongly supported to admit of the summary measures most congenial to his character and most suitable to his political position. Luther was therefore heard, and his safe-conduct respected; but at the close of the diet Charles had the ban of the empire pronounced upon him and his adherents. This edict, however, which had been obtained by unfair means, remained inoperative. The war with Francis which now broke out, and occupied the emperor for eight years, prevented him from obstructing the Reformation. In the meantime, disturbances had been going on in another part of his dominions (1519-21). The discontent of the commons of Castile at the summary proceedings of Ximenes, at the excessive preference given to Flemish

officials in the government of Spain, and at the other unconstitutional measures of the new Government, broke into open revolt. Toledo was the first to rise, and the insurgent cause soon became powerful in Castile. Even many of the nobles sympathized with the movement; one of their number, Don John de Padilla, placed himself at the head of it; but divisions among the commons, and their alienation from the nobility, weakened their strength. An army was brought up against them, which defeated Padilla, and took Toledo after a hard siege. Like disturbances took place in Valencia. On his return from Germany, Charles treated the insurgents with great clemency, and wisely attached the nobility to his person; but the old liberties of Castile became little more than a dead letter.

After his return from the Diet of Worms, Charles remained in Spain till 1529, directing the war against Francis. The emperor was upon the whole decidedly victorious. The French were foiled in Navarre, and expelled from Milan and from the whole of Italy. The failure of the imperialists in an invasion of Provence and the siege of Marseilles was compensated by the splendid victory of Pavia, in which the French sustained enormous losses, and Francis himself was made prisoner (1525). The triumph was, indeed, too decisive, as it made Charles oblivious of every chivalrous principle in his treatment of the captive king, and alarmed his allies, Henry of England and Clement VII., into espousing the French cause. Francis nominally accepted, but immediately after his liberation repudiated the humiliating peace of Madrid, and with his allies recommenced the war. Thus Charles lost the fruits of his victory; but he was again successful. The mercenary army of Bourbon plundered Rome, and kept the Pope a prisoner in the castle of St Angelo, while the efforts of Francis to maintain himself in Italy proved a failure. At length the rival monarchs composed their differences for a time at the peace of Cambray 1529, by which Francis renounced his pretensions to Milan, and retained the duchy of Burgundy. The superior generalship of the Spaniards, the deeper and more persevering policy of Charles, and the defection of Bourbon (who, grievously injured at the French court, carried over to the enemies of his country his military skill and a thirst for revenge) had given him the foremost place in Christendom, in reality as well as in name, while the peace left him free for other labours. Leaving Spain under the regency of his beloved queen, Isabella of Portugal, whom he had wedded in 1526, he proceeded to Italy. At Bologna, where he had an interview with the Pope, he was crowned emperor and king of Italy; and Florence, which had expelled the Medici, was taken after a long siege, deprived of its republican constitution, and placed under a member of that celebrated family. After having arranged the affairs of Italy, the emperor crossed the Tridentine Alps into Germany to attend the diet which had been summoned to meet at Augsburg (1530). Notwithstanding the Peasants' War, the fanaticism of the Anabaptists, and the strenuous, often threatening, opposition of the powers temporal and spiritual, especially of Southern Germany, the Reformation had made marvellous progress during the nine years which had elapsed since the Edict of Worms, and was rapidly overspreading the whole empire. It was clear that if the influence of the church beyond the Alps was not altogether to be lost, the emperor must interpose with the whole weight of his authority. Accordingly, at Augsburg, Charles made every effort to bring about a peaceful arrangement of the religious differences; but he soon found that he had quite mistaken the strength and firmness of the new movement. The Protestants held resolutely by the confession they had presented; and when Charles proceeded to issue a hostile edict against them, they formed

themselves into a league for mutual defence under the leadership of Saxony and Hesse. This was the famous Smalkald League, which from the end of 1530 continued to be the political bulwark of German Protestantism. The league entered into communication with both France and England; but it was from a much stranger quarter deliverance was to come. As at the Diet of Worms it was Francis, so now it was Soliman that averted an armed collision between the young Protestantism and the imperial power. Foiled in his attack on Vienna in 1529, the sultan was again threatening the south-eastern frontiers of Germany with a terrible army. Charles felt it necessary to unite the empire against him, and so at Nuremberg effected a compromise with the Protestants, by which freedom of worship was secured till the calling of a general council. With all enthusiasm they then armed against the Turk. At the head of one of the most splendid armies ever equipped by Christendom, Charles for the first time took the field in person. Great deeds were expected at this hostile meeting of the Eastern and the Western worlds; but the sultan, reckoning on the religious quarrels of Germany, did not anticipate that he would have to confront the united forces of the empire, and therefore soon withdrew within his own frontier (1532). Not being able to follow the enemy through the wasted kingdom of Hungary, the emperor returned through Italy to Spain. His next expedition was against Tunis, now the stronghold of the great pirate Barbarossa. The emperor defeated Barbarossa, took the city, and released thousands of Christian slaves, who, returning to Europe, spread abroad the fame of their generous deliverer (1535). The same year war was resumed with Francis, who formed an alliance with the Turks, and invaded the territory of the duke of Savoy. Charles failed completely in an invasion of Provence, and the war ended without any important result by the truce of Nice (1538). Next year the emperor lost his wife Isabella, to whom he was deeply attached. Towards the end of the year (1539), when a revolt of the city of Ghent required his presence in Flanders, Charles passed through Paris on the special invitation of the French king, giving to Europe, as was thought, a noble example of chivalrous confidence and forgetfulness of past enmities. The emperor was too much occupied with present emergencies to introduce a systematic despotism into the Netherlands; but when the privileges of the cities came into conflict with his imperial plans they were little respected. The most cruel edicts had been issued against Lutheranism and a bloody persecution carried on. But to Charles the Netherlands were above all things an inexhaustible source of revenue, from which he drew the supplies for his many wars. They paid annually twice as much as Spain and the Indies put together, and were continually called upon for extraordinary contributions. The great city of Ghent, his own birthplace, had lately refused to contribute, and even entered into communication with Francis, who betrayed it to Charles. The emperor entered the city with a numerous army and an imposing retinue, caused the ringleaders to be executed, annulled the constitution of the city, and placed it entirely under the government of persons nominated by himself (1540). In the autumn of next year Charles made another expedition against the corsairs of North Africa, who had now made Algiers their great stronghold and the centre of their nefarious power. But he was unsuccessful; a tremendous tempest so disabled the army and injured the fleet that he was obliged to return before he had in the least accomplished the object of the expedition. He had unwisely persisted in it during a highly unfavourable season; but the bravery with which he exposed himself to danger and hardship of every kind to some extent atoned for his rashness. The reverses sustained by the emperor

at Algiers encouraged the most persevering of his enemies, Francis, to renew the war in alliance with the Turks. Consequently, Charles was once more obliged on every side to make head against his old foes, against the French armies in Piedmont and on the Spanish and Flemish frontiers, against the Turkish armies in Hungary, and against a junction of the French and Turkish fleets in the Mediterranean. At length a fresh compromise with the Protestant princes enabled him to invade Champagne with a powerful German army, which so alarmed the French capital that Francis found it expedient to conclude the peace of Crespy (1544). This was the last war of Charles with his French rival. The emperor had all along maintained his superiority over the king, but except that the French had been expelled from Italy, they remained, territorially, as they had been at the beginning.

This peace with Francis, and a truce subsequently concluded with Soliman, now left Charles free to grapple with his last and most difficult labour, the suppression of the Reformation. The religious question always lay very near to the heart of the emperor. But during the first twenty-five years of his reign, it had only been at short and broken intervals, left him by his wars and other multifarious relations with Francis, Henry, the Pope, and the Turk, that he had been able to take it in hand. Scarcely had he been able to enter on some deliberate method of dealing with it when one or other of those rivals or suspicious friends crossed his path, and called his attention elsewhere. And now, when he could devote seven years of almost uninterrupted leisure to the work, and could concentrate the entire strength of his empire on the execution of it, he was destined to discover that the Reformation had grown too strong to be arrested even by his imperial will. Its progress, great as it had been from the Diet of Worms to that of Augsburg, had been far greater from the Diet of Augsburg to the period at which we have arrived. At Augsburg the elector of Saxony and Philip of Hesse were the only considerable princes that supported the Reformation. By this time Württemberg, Brandenburg, the dukedom of Saxony, and the Palatinate of the Rhine had declared for it. Northern Germany was almost entirely Protestant, whilst in Southern Germany the imperial cities, and even to some extent the nobility of the Austrian hereditary states, were in favour of it. Bohemia was strongly inclined in the same direction; and towards the West the orthodoxy of the Netherlands was threatened by the duke of Cleves, who was going to enter the Smalkald League, when his plans were cut short by the emperor, and still more so by Hermann, archbishop of Cologne, who was engaged in inaugurating a moderate reformation of his province under the advice of Bucer and Melancthon. Thus had the new movement profited by the distractions of an emperor who wished to arrest it. Now it was clearly time for the most strenuous and comprehensive effort. It was to be expected of the politic nature of Charles that he would not have recourse to extreme measures till all means of accommodation had been exhausted. Accordingly, in 1541, at Ratisbon, a great religious conference had been held by some of the most moderate theologians on either side. No little harmony of opinion had been arrived at, but they differed as to transubstantiation and the powers of the church, the more decided heads of both parties were afraid that compromise was being carried too far, and the result was that they separated without any common platform being secured. Towards the end of 1545 another of the methods all along proposed for the arrangement of the religious difficulty, and constantly urged on the popes by the emperor, was at length to be tried. But the Protestants were resolved to have nothing to do with a so-called general council which was

composed almost entirely of Italians and Spaniards, where the Pope and the old party were absolutely predominant, and where, consequently, the Church of Germany had no chance of a fair representation or even of a fair hearing. The calling of the Council of Trent, therefore, had the sole effect of widening the chasm between the old and the new; and the course its deliberations were to take had the same result in signaling the contradiction between the Catholic and the Protestant point of view. Perceiving that milder methods were of no avail, Charles now made preparations to compel the submission of the Protestant princes. The dissensions among them greatly facilitated his plans. Maurice, duke of Saxony, always at feud with his kinsman the elector, was ready, with reasonable prospect of self-aggrandizement, to take the imperial side, and the elector of Brandenburg took no active part in the struggle, so that Electoral Saxony, Hesse, Würtemberg, and the imperial cities alone were to be reckoned with. The counsel of the great general Schärflin, who commanded the troops of the cities, to fall upon Charles at Ratisbon before his forces were assembled, and then to seize the passes of Tyrol, so as to break the communication between Italy and the imperial camp, was set aside by the hesitating and over-scrupulous leaders of the Protestant party. Accordingly, Charles was allowed to concentrate his troops and take the offensive. Maurice thereupon declared himself, and, invading the territories of Electoral Saxony, compelled the elector to withdraw from the Protestant camp, which consequently soon broke up, leaving the emperor to have his own way in South Germany, and to suppress the Reformation in the province of Cologne. Thus, disastrously for the Protestants, ended the campaign of 1546, the result of their own indecision, as their forces were superior to those of the emperor.

In the meantime, the Saxon elector had been chastising Maurice for his treacherous invasion of the electorate. In the spring of 1547 the emperor, hastening to assist his ally, concentrated his forces at Eger on the Bohemian frontier, overtook the electoral forces at Mühlberg on the Elbe, defeated them easily, and took the elector prisoner. He was obliged to submit to a humiliating arrangement, by which he resigned his territory and the electoral hat to his enemy Maurice. Shortly after, Philip of Hesse was likewise compelled to yield, and was detained a prisoner by the emperor, whose dishonourable conduct on this occasion excited the indignation of his Protestant allies, especially of Maurice, who was son-in-law to the landgrave. In a little time Protestantism seemed to be at the feet of the emperor. The city of Magdeburg was the only important seat of resistance remaining. But while the emperor had been beating down the enemies of the church on the field of battle, her representatives at Trent were proceeding in such a way as to render a permanent settlement of the question impossible. The politic Charles was anxious to concede certain points to the Protestants, so as to secure peace while still maintaining the rights of the church. The conclusions arrived at by the council did not admit of compromise; and to make matters worse, the Pope, alarmed at the victorious attitude of Charles, removed it from Trent to Bologna. Elated by his victories to an extent that was not to be expected of an old and experienced statesman, the emperor now adopted some very doubtful measures. Under his auspices, the Augsburg Interim was framed—an attempt to supply a common religious platform for all parties in the empire, and thus by his own imperial authority put an end to the schism. But it pleased neither party, for the Catholics rejected it, and the Protestants accorded it only a limited and enforced obedience. Another plan of the emperor, to induce the German electors to cancel the election of his brother Ferdinand as king of the Romans

and to choose his own son Philip instead, also failed. Thus the ambitious dream of Charles to transmit all his own power to his son, and if possible make it hereditary in his family, could not be realized. Meanwhile, all unknown to himself, a plot was maturing by which he was to be hurled from a position of splendid triumph into the bitterest reverses of his life. The profound and skilful Maurice of Saxony, finding that he had got from the emperor all that was to be expected, and perceiving how deeply he had outraged the national and religious sentiment of Germany, resolved to seize the advantage given him by the high-handed and oppressive measures of his ally in order to retrieve his own lost credit. Accordingly a combination of princes was formed with the greatest secrecy, and an alliance concluded with Henry II. of France. While the French king, marching eastward as the "Protector of the Liberties of Germany," seized Toul, Verdun, and Metz, and threatened Strasburg, and the Turks renewed the war on the Austrian frontiers, Maurice and his confederates advanced suddenly into South Germany, and surprised the emperor at Innsbruck, whence, saved from capture by a mutiny among the German landsknechts, he fled, sick of gout, over the Tyrolean Alps into Carinthia. Weary of the religious divisions of Germany, Charles left to his brother Ferdinand the task of arranging a peace, first at Passau (1552), and finally at Augsburg (1555). But he was doomed ere long to sustain another severe reverse. While renouncing the task of arranging the internal affairs of Germany, he had chosen for himself the duty of chastising her foreign enemies, and winning back an important possession. At the head of a splendid army of 60,000 men, he besieged Metz from the end of October 1552 to the beginning of January; but all his efforts to retake the city availed nothing against the skill of Guise, and the bravery of the French nobles, who had thrown themselves into the city in great numbers. After suffering great losses he was obliged to retreat, and Metz was for three centuries lost to the German empire. Soon after, in a very different quarter, the policy of Charles gained a great triumph, which likewise proved illusory. The frequent changes in the direction of English politics had always been a subject of deep interest to him, and had to some extent affected his own course, though only in a secondary way. Now, however, on the accession of Mary, there was real ground for the hope that England might be drawn into the closest connection with his policy, and most intimately interested in the great struggle against the new movement, which had gradually become the supreme question in European politics. Mary had already been betrothed to Charles, and expressed her willingness to become his second empress; but he transferred the state duty of marrying Mary to his son Philip, who accordingly did so in 1554. The presence of Philip in England contributed greatly to the restoration of Catholicism in the country, and Mary was very glad to fall in with the general policy of Charles. An heir only was wanting to the stability of the union, an heir, too, who was destined by the marriage treaty to rule over England and the possessions of the house of Burgundy, and his birth was expected with many prayers in the Catholic world, and with great anxiety on the part of Charles. Happily for England, the hopes of Mary were not realized. The English alliance continued, but its insecurity was only too apparent.

Long before the period at which we have arrived, Charles had entertained the idea of relinquishing the throne in order to devote the remainder of his life to quiet retirement and preparation for another world. With a feeling of this kind it had been purposed by him and his wife Isabella, who died in 1539, to withdraw, he into a monastery, she into some neighbouring nunnery, and there spend the

evening of their days in religious exercises. On his return from the unhappy expedition against Algiers his suite remarked the impression made on him by the quiet simplicity of the monastic life. In 1542, the secret had been confided to Francisco Berja, afterwards famous in the Society of Jesus. Now when he had been thwarted in his dearest schemes, obliged to renounce all pretension to control the religious movement in Germany, and foiled in a great attempt to recover an imperial city treacherously seized by his bitterest foes, and when the last great effort of his statesmanship depended on the life of a sickly woman, it is no wonder that he proceeded to carry his plan into execution. But beyond a doubt the great reason for finally adopting the resolution to abdicate was his feeble health. The vigour which in his younger days had fitted him so well for the chase, the tournament, and the battle-field, was already completely undermined by incessant labour and anxiety, by repeated attacks of gout, and, it must be added, by the most extraordinary excess at table. In 1554 he transferred the crown of Naples to his son Philip, in order that Philip might marry Mary of England on equal terms. Next year, on the 25th of October, the States of the Netherlands were assembled at Brussels to receive a formal abdication of those provinces. Supported by a crutch on the right hand, the left leaning on the shoulder of the young prince of Orange, afterwards renowned as the liberator of Holland, Charles recounted the many journeys he had made and the long and arduous labours he had undergone in the service of his people; he intimated that the state of his health now required that he should transfer the cares of government to his young son, whom he introduced to the assembly; and, exhorting them to adhere steadfastly to the Catholic faith, requested their forgiveness of all the errors committed during his reign. The assembly, full of the ancient spirit of reverent loyalty, and struck by the marvellous spectacle of the highest earthly power voluntarily divesting itself of its majesty and descending into obscurity before the natural time, burst into tears and sobs. The emperor himself, as he sunk exhausted in his chair, wept like a child. The same year Charles intimated to his brother Ferdinand his determination to resign the imperial dignity; but owing to the tedious formalities of the empire, and the objections of Ferdinand, it was not till 1558 that the process of abdication was completed. In the beginning of 1556 he formally laid down the crown of Spain.

After he had thus relieved himself of the responsibilities of government, Charles sailed from Flushing on the 17th September for a climate better suited to his broken health. He landed at Laredo in Spain on the 28th, and in the beginning of February of next year finally settled at Yuste, a Hieronymite monastery in the north of Estremadura. It stood in a pleasant and genial valley, protected from the north wind by a range of mountains. He had selected the spot some time before, and had caused a house to be built for his reception adjoining the monastery. Here he stayed till his death, a period of one year and eight months nearly. His life in retirement, so erroneously painted by Robertson, has been described with great minuteness by many recent historians of great ability. The romance in which it has been enveloped has been done away, and his character appears in unborrowed and somewhat prosaic reality. It is true that he devoted much of his time to religious exercises; for it was not to be expected that a prince, who had not allowed a single day to pass since the age of twenty-one without spending a portion of it in inward prayer, would intermit the practice in his declining years, and during a retreat chosen for the purpose. He spent much of his leisure in gratifying his mechanical tastes, but so far was he from learning the principle of toleration from

the impossibility of making two watches go exactly alike, that he exhorted his children, in the most urgent manner, to destroy heresy with fire and sword. He still delighted in the converse of learned and experienced men, but instead of entertaining them familiarly at table he maintained the stately Castilian etiquette of dining alone, only once deigning to partake of the meal of the friars, whom he continued to respect as much as ever. The simplicity of his table especially is a mere imagination. So long as he was tolerably well he kept his dependents in continual anxiety to have it well furnished with those pernicious dainties which had contributed to ruin his health, and this was only equalled by the anxiety of his medical and other advisers, when excess had brought about its natural consequences. His retirement certainly delivered him from the necessity of moving in a prescribed line of anxious duty and responsibility, but his own sympathy with public affairs, and the emergencies in which Philip found himself in consequence of a new combination of the French, the Turks, and the Pope, obliged him to come forward with his advice, which was always attended to with the utmost deference, and in financial matters, with his active help. The couriers despatched to Yuste found him keenly alive to all the vicissitudes of good and evil fortune which his empire was still destined to experience. The brilliant, but somewhat barren victories of St Quentin and Gravelines, the extraordinary peace concluded by Philip with the Pope, the loss of Calais and Thionville, the advance of the Turkish fleet to the coast of Spain, and the much-desired but never to-be-fulfilled hope of Mary of England, that God might give her a child for the good of the church—all these matters interested him as much as when he was the moving spirit of European politics. The soft air of Yuste and the easy way of life he led had for some time a most beneficial effect on his health. He became stronger than he had been. But his gout, and above all his injudicious diet, still rendered him an invalid. He could not ride, nor could he walk much, but was usually carried about in a chair, and delighted to enjoy the warm air under the shade of the trees of the monastery. At length, during the month of August 1558, serious symptoms began to show themselves, and it was remarked that his mind dwelt more than ever on the religious ceremonies prescribed by the church for the souls of the dead. The Hieronymite chroniclers relate that he even caused his own obsequies to be performed before his death. There are a good many difficulties in the way of accepting their narrative; but Sir W. Stirling Maxwell and Prescott are both disposed to believe that his funeral service was in some form celebrated during his life. The same day, the 30th August, he felt considerably worse. In a little time his ailment took the form of fever, of which he expired at two o'clock in the morning of the 21st September (1558). He died the death of a good Catholic, earnestly commending his soul to God according to all the forms observed by the church. He was interred in the monastery; but after the completion of the Escorial by Philip, his remains were removed thither, where they were again laid to rest by the side of his dearly beloved and much regretted Isabella.

An important point in the codicil to his will, executed some days before his decease, must be mentioned for the light it throws on the character of Charles and on the subsequent history of Europe. In the very year of his death the most conclusive proof had been given of the influence of Luther's teaching even at the court and round the throne of Spain. At the time of this alarming disclosure Charles had urged the severest measures for the extinction of heresy, and now in this codicil he enjoined his son in the solemnest manner to root it out. Thus the last energies of the emperor were spent in consecrating that

terrible system of religious policy which led the different branches of his house into the fatal crusade against the Reformation, set one-half of Christendom in arms against the other, and permanently arrested the development of Southern Europe. As to Luther and the Diet of Worms he regretted that respect for human engagements had led him to forget his duty to God in permitting the arch-heretic to escape, but congratulated himself that he had never exposed his soul to contamination by hearing the new doctrines defended in his presence, as if ignorance were the only sure safeguard of truth. At the same time, those who would see in this proof of a blood-thirsty disposition entirely mistake the character of Charles or the state of the Spanish conscience. Charles was neither cruel nor cold by nature; he was popular among all classes and nationalities of his subjects, clement to rebels, revered by his immediate attendants, loved by the members of his own family, and deeply attached to his wife. Conscious that he was by divine right the political head of Christendom, he did not evade or depreciate the duties such a position imposed, but exerted himself to the utmost and in a religious spirit to fulfil them, though by no means unwilling to employ all the arts permitted by the statesmanship of the time. In fact he fulfilled better than most men the mission which his experience and position imposed and his education enabled him to comprehend, and of this he considered the suppression of opinion destructive of the church the most indispensable part, quite as obligatory as the defence of Christendom against the Turks and the corsairs, more so than the assertion of his imperial dignity against the Pope, or of the rights of the house of Austria against the French. But his conscientious conviction of the necessity of suppressing heresy neutralized all the excellencies of his character. It was not so much in what he did, as in what he was not permitted to do, that his reign was helpful to the civilization of modern Europe.

The memoirs of Charles, dictated by him in leisure hours while sailing up the Rhine in 1550, were discovered in 1861 by Baron Kervyn de Lettenhove, while making some searches in the Imperial Library at Paris. The manuscript was in Portuguese, and professed to be a translation made from the original at Madrid in 1620. That such memoirs had existed was well known from the testimony of Van Male, literary secretary to Charles, and from other contemporary notices; and their existence was affirmed in 1623 by Gonzalez d'Avila, historiographer of Philip III. They were written in French in a concise and dignified style, and give a brief summary of his life from 1515 to 1548,—very brief at first, somewhat in detail from 1545 to 1548. English translation by L. F. Simpson (Lougmans, 1862).

Stirling Maxwell's *Cloister Life of Charles V.*; Prescott's Appendix to Robertson; Pichot's *Chronique de Charles-Quint*; Gachard's *Retraite et mort de Charles-Quint*, and Mignet's *Charles Quint*, all which works are based on researches into the archives of Simancas, especially on those of Gonzalez. (T. K.)

CHARLES VI. (1685–1740), emperor, was the second son of Leopold I. As the only male representative of the house of Hapsburg, he claimed the throne of Spain, which was left by Charles II. to Philip, duke of Anjou, grandson of Louis XIV.; and in order to prevent the predominance of the house of Bourbon, England, Holland, Prussia, Germany, and Portugal gave him their support. In 1703 he was proclaimed at Vienna; and having, after a visit to England, invaded Spain, with the assistance of an English fleet under Peterborough and an English land-force under the earl of Galway, he was proclaimed king in Madrid in 1706. He himself remained at Barcelona; and the war continued with varying success, till the death of his brother, the Emperor Joseph I., in 1711, produced the most important changes in the policy of the allied European powers. They became as much afraid of the supremacy of the house

of Hapsburg as they had formerly been of that of Bourbon; and in 1713, by the treaty of Utrecht, they made peace with France. In the next year Charles was obliged to follow their example, and by the treaty of Rastadt he gave up all to Philip except the Spanish possessions in the Netherlands and Italy. In 1715 Charles undertook the defence of Venice against the Turks; his general, Prince Eugene, gained some considerable successes, including the victory of Belgrade; and, at the conclusion of peace in 1718, he added Belgrade, and parts of Servia, Slavonia, Bosnia, and Wallachia to the empire. He was next engaged in meeting an attack on his Italian territory made by Spain, whose policy was then directed by Alberoni; and, with the assistance of England, France, and Holland, he was speedily successful. After this for several years all his efforts were spent in endeavouring to obtain the recognition by the European powers of his Pragmatic Sanction of 1713, which settled the succession on his daughter, Maria Theresa, and her heirs. By ceding Parma and Piacenza, Charles purchased the favour of Spain, and he afterwards in a similar manner acquired the alliance of Russia and Prussia. But England, France, Denmark, and Holland united to oppose him; and it was only at the cost of considerable sacrifices that he at length, in a conference held at Vienna in 1731, obtained their recognition of his scheme. One of the promises which he then made was to secure the succession to the crown of Poland to the son of the reigning king; and on the death of the latter he was consequently involved in a war with France, Spain, and Sardinia, which supported a rival claimant. In this struggle he lost Milan, Lorraine, and most of Lombardy, which were seized by the French, together with the two Sicilies, which were conquered by the Spaniards. His last war, against the Turks, was equally unfortunate. He died in 1740, leaving the empire considerably weakened by his reign.

CHARLES VII. (1697–1745), emperor, also known by the name of Charles Albert, was the son of Maximilian Emmanuel, elector of Bavaria. He was taken from home while a child by the Emperor Joseph I., who had outlawed his father, and seized Bavaria; and he was not liberated till the conclusion of the treaty of Rastadt in 1714. He commanded against the Turks in the war which the Emperor Charles VI. undertook in order to protect the Venetians. In 1722 he obtained in marriage the second daughter of the late Emperor Joseph, after renouncing all claims to the imperial crown. But when he succeeded to the electorate of Bavaria (1726), he refused to recognize the Pragmatic Sanction; and on the death of Charles VI. he gained the alliance of France and Spain, proclaimed himself king of Bohemia, and, having obtained his own unanimous election, was crowned as emperor at Frankfurt in 1742. The Hungarians, however, having espoused the cause of Maria Theresa, she was enabled to occupy Upper Austria and Bohemia, and Charles was forced to retire. In the next year his general, Seckendorf, met with some success, and in 1744 Frederick of Prussia invaded Bohemia in his interest. Charles died at Munich in 1745.

CHARLES I. of Spain. See **CHARLES V.**, emperor.

CHARLES II. (1661–1700), king of Spain, son of Philip IV., was only four years old at the death of his father. The regency was left in the hands of the queen, Anna Maria of Austria. She appointed a council, at the head of which she placed Neidhard, her confessor, whom she also made grand inquisitor. But Don John, the illegitimate son of the late king, having gained great popularity by his military successes, marched on Madrid, and forced her to dismiss Neidhard, and give to himself the vice-royalty of Aragon. An unsuccessful war with France, and the loss of Sicily further weakened her power; and in 1675

Charles assumed the government, and took Don John as his chief adviser. Still Spain continued to suffer in the great European contest; and in 1678 she was forced, in the treaty of Nimeguen, to cede Franche-Comté and several considerable towns in the Low Countries to France. In the next year she sustained another serious loss in the death of her ablest minister, Don John. Immediately after the treaty of Nimeguen, Charles espoused Louisa of Orleans, a niece of Louis XIV., who for the next eleven years maintained harmony between Spain and France. The queen-mother now left the retirement of the convent in which she had been placed, and once more, amid the empty folly of the king and the court, assumed considerable authority. After the death of Louisa, Charles married Anne, a sister of the Emperor Leopold I.; and in 1694 he joined the country of his wife and of his mother in declaring war against France. But he effected nothing, and the French troops had reached Barcelona, when Spain was saved by the treaty of Ryswick (1697). As the king was childless, negotiations concerning the succession occupied the last years of his life, and after leaning for a long time to the side of Austria, at last, a month before his death in 1700, greatly through the influence of the Pope, he left the crown to Philip Bourbon, grandson of Louis XIV., who succeeded as Philip V.

See *Spain under Charles II.*; extracts from the correspondence of Alexander Stanhope, British ambassador at Madrid from 1690 to 1700, edited by Mahon (Lond. 1840), and Mignet's *Négociations relatives à la succession d'Espagne*.

CHARLES III. (1716-1788), king of Spain, was the second son of Philip V. Parma, Piacenza, and Tuscany, having fallen into the hands of Spain, were bestowed upon Charles, who at the age of fifteen was furnished with an army, and sent to take possession of his principality. At eighteen he conquered the two Sicilies, and the emperor was obliged to recognize him as king. In 1759, by the death of his brother, Charles succeeded to the throne of his native country. His reign was a useful one; for he was a man of ability and of liberal temper, and he was served by such ministers as Aranda, Grimaldi, and Florida Blanca. The administration of the finances was reformed, and a bank was instituted at the capital. The Jesuits were banished, and an attempt, which was not, however, successful, was made to bring the Inquisition under the power of the civil government. Something was done to abolish brigandage; and on two occasions Charles endeavoured to repress the piracy of the Algerines; he interested himself greatly in the development of commerce, science, and art; and, lastly, he did much to strengthen the army and navy. The wars, however, which he carried on with England, in alliance with the French, brought him little success. In 1763 he ceded Florida to the English in exchange for Cuba. He joined France in sending assistance to the United States during the War of Independence; and in the peace which was concluded after that war, he recovered Florida, and also gained Minorca. But his attack on Gibraltar was unsuccessful, and the English refused to treat for its restoration. Charles died at Madrid in 1788, after a reign of twenty-nine years. See the *Elogio* of Cabarrus, and the accounts of the reign by Beccatini and Roy.

CHARLES IV. (1748-1819), king of Spain, was the son of Charles III., whom he succeeded in 1788. He was married while very young to his cousin, Maria Louisa of Parma, who soon acquired the greatest influence over him. His most remarkable minister was Manuel Godoy, a good looking guardsman, who gained the friendship of both the queen and her husband, rose from the ranks to the position of lieutenant-general, and was made duke of Alendia, and minister of foreign affairs. In 1795 Godoy concluded a treaty of peace with the French Republic at Basel, after

an unsuccessful attempt by the king to aid his relative, Louis XVI. Soon after the peace an offensive and defensive alliance was entered into with France; and Spain was thus involved in a short war with Portugal and a longer struggle with England, during which Nelson shattered the Spanish fleet at the battle of Trafalgar (1805). In 1807 Charles made a secret treaty with Napoleon, according to which Portugal was to be seized by the French and Spaniards, and the greater part divided between Godoy and the queen of Etruria, and Charles was to assume the title of emperor of America. At the same time 16,000 Spanish troops were sent to assist the French in Denmark. Meanwhile Napoleon also carried on intrigues with Don Ferdinand, the heir to the throne, who was soon after discovered in a plot to assassinate his father. Though pardoned, Ferdinand continued to do all that he could to arouse ill feeling against the court; and in 1808 Charles was so alarmed by disturbances in Madrid, that he abdicated in his favour. He declared almost immediately that the act was not voluntary; but the matter was decided by a meeting with Napoleon at Bayonne. Urged by Godoy, who was moved by his fear of Ferdinand, and also by the queen, Charles surrendered the crown to Napoleon, who gave him a pension of 6,000,000 francs with the castle and grounds of Chambord; and from that time he lived in retirement with his wife and the favorite, refusing to return to the throne, even when he might have done so with safety on account of the great unpopularity of his son. He died at Rome, soon after the decease of his wife, in 1819.

CHARLES IX. (1550-1611), king of Sweden, was the fourth son of Gustavus Vasa. His nephew, Sigismund, king of Poland, who inherited the crown in 1592, being a Roman Catholic, Charles was appointed to direct the government, till Sigismund signed a decree establishing Lutheranism as the religion of Sweden. There was also a general feeling against the occupation of the throne of Sweden by a Polish king, and, after several fruitless attempts at accommodation, Sigismund was deposed and Charles elected king in 1604. He carried on a vigorous war with Poland, Russia, and Denmark with varying success; and at the age of sixty he challenged (though without result) Christian IV., the king of the last-named country, to single combat. Many of his domestic measures were very beneficial. He founded the university of Gothenburg, and otherwise furthered the spread of education; and he drew up a new code of laws. He left a rhymed chronicle, and a number of letters addressed to Henry IV. of France and others, on the subject of the war with Poland, which were printed in German at Amsterdam in 1608. He died in 1611.

CHARLES GUSTAVUS X. (1622-1660), king of Sweden, was the son of John Casimir, Elector Palatine of the Rhine, and of Catherine, daughter of Charles IX. of Sweden. He studied at Upsala, and travelled in France and Germany, took part in the Thirty Years' War, and fought at Leipsie and elsewhere. On his return to Sweden he sought the hand of his eccentric cousin, Queen Christina, whom he professed to love sincerely. He was rejected; but in 1654 she voluntarily abdicated the throne, and was succeeded by him. He had now an opportunity of gratifying his passion for war. In 1655 he overran Poland, on the pretext that the king had protested against his accession and desired to supplant him. The kingdom of Poland, and after that the dukedom of Prussia, were compelled to swear allegiance to him, and Charles next seized the continental territory of Denmark. He proposed to Holland and England a plan for dividing Denmark among the three nations, but Cromwell scornfully refused to share in the robbery. Charles was still fighting against Denmark when he died at Gothenburg (1660) in his 38th year.

CHARLES XI. (1655-1697), king of Sweden, was five years old at the death of his father, Charles X., and was left under the regency of his mother and of a council. Brought up without care, he arrived at manhood unable even to read. In 1672 he assumed the government, and, under the influence of France, was speedily engaged in the invasion of the electorate of Brandenburg. The elector was assisted by Denmark and Holland; and Charles's army at first met with serious reverses; but afterwards, taking the command in person, he won several battles, including those of Lund and Landskrona; and in 1679 peace was signed. Charles now devoted his energy to establish the absolute independence of the kingly authority. He diminished the number of senators, and made them mere royal councillors; he reunited to the Crown all the lands which had been divorced from it since 1609; and in December 1682 the States were induced to declare that the king was responsible for the use of his authority to none but God, that he was not bound by forms of government, and that he need only seek the consent of the senate at his own pleasure. The power thus gained was creditably used for purposes of government. Charles paid the public debts, published annual accounts of the finances, travelled through the country that he might be personally acquainted with the needs and circumstances of the people, defended them from the tyranny of the nobles, established a strong and just legal administration, and commenced the drawing up of a general code. He also added largely to the territory of the kingdom. Under his reign no religion was tolerated but Lutheranism; and the king often showed himself stern and rough. He died at Stockholm in 1697.

CHARLES XII., king of Sweden, was born at Stockholm on June 27, 1682. He received an excellent education, and was able to speak German, French, and Latin fluently. In the spring of 1697 his father, Charles XI., died, and the prince, then only in his fifteenth year, was declared of age by the States-General and invested with the royal authority. As might have been expected, the boy-king showed himself but little disposed for state affairs. His time was divided between study and amusement; now he was poring over the exploits of Alexander in the pages of Quintus Curtius, now spending whole hours in gymnastic exercises, or joining a hunting party in the pursuit of the bear; and thus he was rapidly developing the iron strength of constitution which he displayed in his subsequent campaigns. At this juncture Frederick IV., king of Denmark, conceived the idea of wresting the crown from the young king, and adding Sweden to his possessions in the Scandinavian peninsula, and Augustus II., king of Poland and elector of Saxony, and the czar, Peter the Great, agreed to second his enterprise by seizing the continental provinces of Sweden. The Danes struck the first blow by invading the territories of Holstein Gottorp, and the duke, who had married the sister of Charles, fled to Stockholm and begged for assistance to recover his states. Charles proposed immediate operations against Denmark, confident in his own prowess and in promises of substantial aid received from the court of St James's, for William of Orange saw in Sweden a valuable ally for his Continental policy, and was resolved not to allow the balance of power in the north to be destroyed by the triple alliance. Sir George Rooke, with an Anglo-Dutch squadron, formed a junction with the Swedish fleet, and at the head of fifty-four sail of the line swept the Baltic, drove the Danish fleet into Copenhagen, and bombarded the city, doing, however, little damage. Meanwhile Charles had landed in Zealand with a Swedish army, leading his troops to the shore in person, and wading through the water up to his chin in his eagerness to land. The Danes, inferior in numbers, retired before him, and Frederick seeing his capital threatened

with a siege by land and sea, abandoned the triple alliance, and sued for peace, leaving Charles free to turn his arms against Russia and Poland.

From this campaign we may date Charles's assumption of those Spartan manners which distinguished him for the rest of his life. He gave up the use of wine; at night he slept upon his cloak spread upon the floor of his room or on the ground in the open air. His dress was of the plainest, his whole wardrobe consisting of a suit of blue cloth with copper buttons. He seemed to care for no pleasure or amusement; he had an amount of endurance which defied fatigue, and he was alike insensible to the heat of summer and the almost arctic cold of a northern winter. Hardy, brave to the extent of recklessness, capable of inspiring in his followers personal devotion to himself, and with all that astute and sagacious in council, he was the very model of a soldier king. Yet in the end Sweden reaped no advantage even from his victories. He had left Stockholm to defend the country from a pressing danger, but once he had tasted the pleasures of military success, he allowed himself to be allured onward to a career of conquest, and he never saw his capital again.

When Frederick sued for peace, Peter the Great was threatening Narva and the Swedish province of Livonia on the Gulf of Finland, while Augustus II., elector of Saxony and king of Poland, was besieging Riga, then a Swedish town. Charles disembarked in Livonia with 20,000 men. The Russian army, said to have been 50,000 strong, lay before Narva in an entrenched camp. With 10,000 of the splendidly disciplined infantry of Sweden, Charles attacked them there on November 30, 1700. In a quarter of an hour the camp was stormed, and the Russian army, which must have been largely composed of raw troops, was completely routed and dispersed. Turning southward, Charles marched against the Saxons and Poles, defeated them on the banks of the Dwina, and raised the siege of Riga. He might now have dictated a peace which would have given Sweden an undisputed pre-eminence in Northern Europe. But his ambition was aroused; Augustus was by no means a popular king, and while continuing the war against him, Charles intrigued with the party adverse to him in Poland. The Saxon army of Augustus was defeated in the battle of Clissow (1703), and Poland was occupied by the victorious Swedes. Radziejowski, the cardinal primate, declared the throne vacant, and under the influence of Charles, the diet conferred the crown upon his friend Stanislas Leszczynski, the young palatine of Posnania. But even now Charles would not sheath the sword. He carried the war into Saxony, overran the hereditary states of Augustus, and in 1706 dictated to him the peace of Altranstadt, by which Augustus resigned all claim to the throne of Poland, and further agreed to give up to the conqueror John Reginald Patkul, the ambassador of the czar at Dresden. Patkul was by birth a Livonian, and therefore a subject of Sweden, but he had transferred his allegiance to Russia, and it was said that he was the real author of the league between Russia, Poland, and Denmark. It was very doubtful if he could have been adjudged guilty of treason, and in any case his position as ambassador ought to have protected him; but Charles thought only of vengeance, and after the form of a trial had been gone through, Patkul was condemned to be broken on the wheel, and the cruel sentence was executed, the king refusing to mitigate it in the least degree. The whole affair has left an indelible blot upon his memory, and it shows how much of vindictive passion was concealed under a perfectly impassive exterior. Even had Charles been willing now to bring the war to a close, the execution of his ambassador would not have allowed the czar to accept a peace. Twice he invaded Poland, but each

time he had to retire before the Swedes. By the autumn of 1707 Charles had collected 43,000 men in Saxony; a reserve of 20,000 under General Levenhaupt was in Poland, and a third army, 15,000 strong, was upon the frontier of Finland. In the following January, in the midst of the ice and snow, he suddenly broke up his camp, marched against the Russians, surprised and almost captured the czar at Grodno, and then continued his advance, driving the Russians before him, and defeating them in numerous encounters. He had forced the Beresina and won a battle near Smolensko, and the way to Moscow lay almost open before him, when, to the surprise of his army, he turned southward to the district of the Ukraine. The fact was that he had a secret treaty of alliance with the hetmann of the Cossacks of the Ukraine, Mazeppa, whose romantic story has been made so famous by the verse of Byron. The hetmann had promised to join the Swedes with 30,000 Cossacks and abundant supplies. But when, after a difficult march, Charles reached the Ukraine, he found that the Russians had discovered and frustrated Mazeppa's design, and the hetmann brought him only a handful of followers. Nor was this his only disappointment. A reinforcement of 15,000 men under Levenhaupt was intercepted and cut to pieces by the czar, and after wasting the summer in a desultory warfare, the Swedes found themselves overtaken by the severe winter of 1708-1709 in the midst of an enemy's country. Still Charles would not abandon the idea of reaching Moscow. Though his army was reduced by cold and privations to 23,000 men, he maintained himself till spring, and then besieged the fortress of Pultowa. The place held out until July, when the czar approached at the head of a large army. On the 7th Charles was wounded in reconnoitring the enemy. In the famous battle which took place next day he had to be carried in a litter amongst his staff. The battle ended in the complete defeat of the Swedes. Charles, leaving most of his officers prisoners in the hands of the enemy, fled with a few attendants across the Bug into the Turkish territories, and was hospitably received by the Turks at Bender on the Dniester.

Charles resided three years in Turkey, during all which time his expenses, and those of his numerous household, were paid by the Turkish Government, in accordance with a very liberal interpretation of the Eastern law of hospitality. From the day of his arrival at Bender his constant aim was to involve Russia and Turkey in war. He succeeded in producing an outbreak of hostilities; the Turks outmanœuvred and surrounded Peter and his army on the banks of the Pruth, and the czar would have been either killed or taken had not his wife Catherine, by her energy and courage, obtained an armistice for him on favourable terms from the grand vizier. Removing his residence to Vranitza, where his followers formed a little camp around the strongly-built house in which he lived, Charles continued his intrigues to produce another war with Russia, and though once on the point of success, he eventually failed, and the counter-intrigues of the czar began to produce an effect at Constantinople. At this time Charles occupied a very humiliating position, short of money, afraid to leave Turkey for fear of falling into an enemy's hands, dreading at any moment to be betrayed by the Turks, and knowing that all his conquests had been useless, and that the Swedish provinces were being invaded by Danes, Saxons, Poles, and Russians. The Porte displayed a singular amount of patience in treating with him, but at length it became evident that so long as Charles felt himself safe among his Polish and Swedish guards at Vranitza he would not leave Turkey. A fetva of the Sheikh-ul-Islam declared that the rights of hospitality would not now be violated by his forcible removal, and Ismaël Pacha, the governor of the district, received orders to seize him dead or alive.

Charles having persistently refused to come to terms, Ismaël, with several thousand janissaries and Tartars, surprised the little camp and took his 300 guards prisoners; he then attacked the house held by Charles and forty of his suite. The king defended himself desperately; the house was set on fire over his head, and he was retiring, driven out by the flames, when his spurs became entangled, and he fell and was secured and disarmed by the janissaries. His eyebrows were singed and his clothes torn and stained with blood. For a while he was kept in honourable imprisonment, then he was allowed to reside with a few attendants at Demotica, where he still spoke of departing escorted by a Turkish army, and feigned illness in order to gain time for negotiations, which in the end led to nothing. The king of Prussia was desirous of forming a league with him against the czar, and would have secured for him an honourable return to his states, the one condition being that Stanislas should abdicate and Augustus II. be recognized as king of Poland. Stanislas was quite willing to abandon his doubtful claim to the throne, but Charles with characteristic obstinacy refused to listen to the proposal. "If," he said, "my friend Stanislas will not be king, I can find some one else to take his place." At length he saw that there was no chance of the Porte granting his demands, and sending his respectful adieux to Constantinople, he set out suddenly with only two attendants, and travelling unceasingly, riding by day and sleeping in a carriage or cart at night, he passed through the Austrian territories, Bavaria, Westphalia, and Mecklenburg, and thus avoiding the districts held by his enemies, reached his own town of Stralsund, in Swedish Pomerania, late at night, on November 21, 1714, after a journey of sixteen days. He announced himself as a Swedish officer charged with important despatches from Bender. The governor received him at once in his bedroom, and asking for news of the king, recognized Charles by the sound of his voice when he replied, and the tidings of his arrival soon spread through the city, which was illuminated for the rest of the night. The return of Charles only drew more closely the alliance between the powers which had been plotting in his absence the dismemberment of Sweden. Stralsund was besieged by a combined army of Saxons, Danes, Prussians, and Russians. Charles made a protracted defence, but on December 23, 1715, the place was forced to capitulate, the king embarking immediately before the surrender, and taking up his residence at Lund in Scania.

Arrived in Sweden, he took measures to protect the coasts of the kingdom against a descent of his enemies, and with a small army invaded Norway in March 1716; he overran a large part of the country, but was forced to retire for want of supplies. About this time the Baron von Görtz, a German officer, who had during his stay in Turkey become his principal adviser, proposed to him a complete change of policy, and Charles immediately accepted the scheme which Görtz had elaborated, and of which he had already executed some of the preliminaries. He proposed that Charles should make peace with the czar, cede to him the Baltic provinces of Sweden, and gain his alliance. The allies were to replace Stanislas on the throne of Poland and restore the duke of Holstein to his states which had been seized by Denmark. Charles was to invade and conquer Norway, and then land a small army in Scotland, and with the help of the Jacobites, restore the house of Stuart in England, Cardinal Alberoni, then all-powerful in Spain, promising to assist in the accomplishment of this part of the project. The other allies had lately been showing a marked jealousy of the growing power of the czar, and it was no difficult matter for Görtz to detach him from the alliance and negotiate a

peace on the part of Sweden. This first step being successfully accomplished, Charles burst into Norway, speedily occupied several provinces, and in the early winter of 1718 besieged Fredrikshall, a strong fortress, which was regarded as the key of Norway. On Sunday, November 30, accompanied by his staff, and by Signier and Maigret, two French officers in his service, he visited the trenches in the afternoon. Arrived in the foremost trench he found fault with the progress of the work, sent for some more sappers, and leaning on the gabions in front of the trench, himself directed their operations. Night came on rapidly, but still he remained there exposed to the shot of the fortress, for the Danes threw up light-balls, and kept up a continual fire from their batteries. His officers in vain endeavoured to persuade him to retire from his dangerous post, he obstinately refused even to shelter himself behind the gabions, though several of those around him had been struck, and about nine o'clock, when the moon had risen and shining on the snow made the night almost as bright as day, a well-aimed shot struck him on the temple, his head fell forward, his hand instinctively grasped his sword hilt, and his officers running up found him leaning over the gabions dead. A musket ball had passed through his head, destroying his left eye and driving the right out of its orbit. The shot put an end at once to the invasion of Norway, the projects of Görtz, and the power of Sweden in the north of Europe.

Before the end of the following year it began to be whispered that the shot which killed Charles came not from the ramparts of Fredrikshall, but from the Swedish trenches. The two French officers were in turn pointed out as the probable assassins, and Signier in the ravings of fever actually charged himself with the murder. On his recovery he denied it, but his involuntary self-accusation was generally believed in preference to his denial. Others laid the alleged crime upon the Swedish generals Cronstadt and Stieruross, and it was said that they had been bribed to break up the project of Görtz by a successful pistol-shot before Fredrikshall. In 1746 the tomb of Charles XII. was opened and the remains were examined in order to see if in this way the question could be settled. The officials charged with the examination seem to have known very little about surgery. They at first suggested that the hole through the skull was made by a dagger; then apparently misled by their ignorance of the well-known fact that the wound at the point of exit is almost invariably larger than that at the point where the bullet enters, they alleged that the ball had struck the right side of the king's head, which was turned away from the fortress. This naturally confirmed the belief that he had been assassinated, although a great mass of concurrent testimony tended to exonerate every one who had been charged with the crime. To solve the mystery of his death, the body was again examined by Charles XV., so recently as 1859, when a careful examination of the skull by three eminent medical professors led to the conclusion that the fatal shot had been fired from a distance on the king's left, and from a higher level than that on which he stood. Thus it was finally proved that Charles fell, not by the hand of a traitor, but from his recklessly exposing himself to the fire of the fortress.

The character of Charles was a strange mixture of good and evil. In him almost everything was vitiated by a kind of exaggeration. Thus his courage at times degenerated into rashness, his determination into mere obstinacy. While we praise his temperate and simple habits, we cannot be sure that, in despising the ostentation and luxury of his brother kings, he was not actuated by a subtle vanity that made him more proud of the blue coat with copper buttons than another would have been of a richly

embroidered uniform. His victories and conquests are all the more wonderful when we consider how young he was at the time of his greatest achievements. He was only eighteen when he extorted a peace from Frederick of Denmark and defeated the Russians at Narva, and he was only twenty-one when the victory of Clissow made him master of the destinies of Poland. War had not in those days the lightning rapidity of modern times, or Charles might have more than rivalled the victories of the first Napoleon. But he was really little more than a soldier; as a statesman he must be placed below the second rank, and the only result of his reign was the weakening and impoverishment of his kingdom. He found Sweden one of the first powers of Europe, he left her fallen to a secondary place, and she has never recovered her former position.

See the histories written by his chaplain Norberg and by Alderfeld, one of his officers. Voltaire's well-known memoir is useful, but contains several inaccuracies. There are also very full biographies by Fryxell and Lundblad. Among contemporary publications there is a curious account of his wars "by a Scots gentleman in the Swedish service," the first edition of which appeared in London in 1715, before the death of Charles, the second in 1718. The real author was Daniel Defoe. (A. H. A.)

CHARLES XIII. (1748-1818), king of Sweden, was the second son of Adolphus Frederick and of Louisa Ulrica, sister of Frederick the Great. He was educated for the office of high-admiral, and commanded with credit against the Russians. On the accession of his brother Gustavus III., in support of whom he exerted all his influence, he was appointed governor of Stockholm and created duke of Sudermania; and he became regent when Gustavus was assassinated in 1792. In 1796 Gustavus IV. came to his majority, and Charles retired from political life. But when Sweden was threatened by the arms of Napoleon, Gustavus directed his forces with an incapacity so remarkable that the people refused any longer to bear his government. In March 1809 he was obliged to abdicate; and in May the crown was offered to Charles. A year after, Prince Christian, the heir appointed by the States, having died, Charles, yielding to the wish of the nation, nominated Charles Bernadotte prince royal, and gave the government into his hands, though still retaining the title and some of the dignity of king. After occupying this position for eight years, Charles died in February 1818.

CHARLES XIV., king of Sweden. See BERNADOTTE.

CHARLES XV. (1826-1872), king of Sweden and Norway, succeeded to the throne in 1859, on the death of his father, Oscar I., son of Charles XIV. His rule was popular and liberal. The most important event in his reign was the change which was effected in 1866 in the constitution of the Storting, or parliament, which, from that time has consisted not of four but of two chambers—the first being elected by the provincial representatives, the second by the people. In character Charles was generous and kindly, and his disposition is shown in his refusal to sanction capital punishment. He possessed considerable taste for literature and art, and published a volume of poems, which were translated into German by A. Vau Winderfeld (Berlin, 1866). In 1850 he married Louisa, daughter of the king of the Netherlands, by whom he had one daughter, Louisa, who became the wife of Prince Frederick of Denmark. His relations with Denmark were of the most intimate kind, owing to his personal friendship with the king; but during the struggle of that country against the aggressions of Prussia he was obliged to remain neutral, since neither Sweden nor Norway would take up arms. Charles died September 18, 1872.

CHARLES, count of Anjou and Provence, king of Naples and Sicily, born between the years 1220 and 1226, was the ninth son of Louis VIII. of France.

He married Beatrice, heiress of Provence, after scattering his rivals by the aid of an army furnished by his brother, Louis IX. Soon after he accompanied the king on a crusade, during which he fought with bravery, but achieved no permanent success, and he was at last taken prisoner with his brother. During his absence most of the towns of Provence formed themselves into republics; but on his return they were quickly subdued, and, among others, Marseilles lost the independence she had before enjoyed. Charles's power was now very considerable; but his ambition was far from being satisfied. He therefore unscrupulously lent his arms to Margaret of Flanders, who offered him the province of Hainault in return for his assistance in setting aside her husband's children by a former wife in favour of her own; but this scheme was crushed by Louis, who caused him to give up Hainault for a sum of money. Charles had now, besides, conceived a loftier ambition. He had been requested to assume the crown of the two Sicilies by Pope Urban IV., who desired to overthrow the bastard Manfred, the Ghibelline king; and in 1265 he was crowned at Rome. A crusade was preached against Manfred, who was defeated and slain. The legitimate heir, Conradin, was also routed (1268), and being betrayed, was meanly tried and executed; a similar fate befell a large number of Italian nobles; many fiefs were confiscated to reward the French followers of the new king; and the rule of the Provençals was often arbitrary and brutal. Charles's ambition continued to widen. He now designed to make himself the head of the Eastern empire. With this end in view, he again accompanied his brother on a crusade; but the accomplishment of his ultimate design was prevented by a terrible storm, and by the outbreak of the plague. He also incurred the enmity of the Pope, Nicholas III., by haughtily refusing to accept the hand of his niece for his own grandson. Nicholas joined the Ghibellines, and took from Charles, who offered no resistance, his titles of senator of Rome and vicar-general of Italy. But in 1280 Nicholas died, and Charles, by means of many intrigues, and after imprisoning two of the cardinals, effected the election of a Frenchman, Martin IV. In return, he was made senator of Rome, and his rival, the Emperor Michael Palæologus, was excommunicated. Another expedition was already fitted out against the East, when news was brought of the rebellion known as the Sicilian Vespers. Aroused by the rough rule of the French, the people were also stirred by the burning exhortations of John of Procida, a Calabrian doctor, formerly friend of Frederick and of Manfred, who had been travelling in disguise through Italy, Greece, and Spain, seeking assistance against the usurpation of Charles. On Easter Monday, 1282, he collected a large assembly of the Sicilian nobles at Palermo. An opportune pretext for a rising soon occurred. The viceroy had forbidden the bearing of arms; and, on the pretext that weapons were concealed under her dress, a Frenchman insulted a girl of noble family on her very passage to the church where she was about to be married. He was killed on the spot, and every Frenchman in the city soon shared his fate. Some of the other Sicilian towns followed this example; others expelled the French more mildly. Charles at once directed his fleet against Messina. He refused all offers of capitulation, and Messina held out till aid was brought it by Don Pedro of Aragon, and Charles's fleet was burned by the famous sailor, Roger de Loria. Charles, despairing of other means of success, now challenged Pedro to single combat. Pedro accepted the challenge, but Charles alone entered the lists. It is said that the former was dissatisfied with the arrangements, though others regard his acceptance as a mere ruse. Soon after Charles's son was defeated and taken prisoner, and in 1285 Charles himself fell ill, and died at Foggia.

CHARLES II. (1332-1387), king of Navarre and count of Evreux, was a grandson of Louis Hutin, and possessed a title to the French throne inferior to that of John II. only on account of the Salic law, and superior to that of Edward III. of England. Handsome, clever, eloquent, and bold, he yet thoroughly deserved the title of "the Bad" with which he mounted the throne in 1349, at the age of sixteen. The commencement of his notorious career was the assassination of Le Cerda, the favourite of John, who had been appointed to the duchy of Angoulême, which the king had bought from Charles's mother, but of which the price was not yet paid. For this deed,—which Charles openly avowed, declaring it to be a punishment richly deserved,—John was at first unable to retaliate, being indeed obliged to make good his debts; but not long after (1356) Charles was seized and thrown into prison. During the king's exile in England, Charles, aided by the States-General, obtained his release, and by his eloquence and the suavity of his manners gained the hearts of the Parisians, who made him their captain-general. Suspecting him, however, of too great favour for the aristocracy, they deprived him of the office; but he maintained his alliance with Stephen Mareel, and, at the head of companies of banditti he continued to lay waste the country till 1360, when he made peace with the king. This peace was not final, for Charles V. was resolved to crush him. He was accused of various unscrupulous plots, and extravagant stories were circulated against him, as, for example, that the king's weakness was due to poison administered by his contrivance. On the charge of being concerned in these intrigues, two of his ministers were executed, and his two sons were seized as hostages. The duke of Anjou was persuaded to attack Montpellier, the king of Castile to invade Navarre, and Duguesclin was sent to seize his fiefs in Normandy, and Charles was obliged to yield twenty places as security before he regained his territory. According to the popular story, he expired by a divine judgment, through the burning of the clothes steeped in sulphur and spirits in which he had been wrapped as a cure for a loathsome disease caused by his debauchery; but the bishop who attended him affirms that he died placidly and in the odour of sanctity (1387). See Secousse, *Histoire de Charles le Mauvais*.

CHARLES IV. (1421-1461), king of Navarre, was the son of John of Aragon, and of Blanche, daughter and heiress of Charles III., king of Navarre. On her death the throne belonged to Charles, but his father retained it, and took as second wife the ambitious and unscrupulous Jeanne of Castile. Charles did not press his claim, but devoted himself to literature, until his step-mother roused him by repeated indignities. He succeeded in having himself crowned, but soon after was defeated and imprisoned (1452). Next year he was released; the struggle recommenced, and he gained possession of a considerable part of Navarre. He was reconciled to his father, and recognized as king of Barcelona; but Jeanne caused him to be arrested and poisoned. He was a man of gentle disposition, and of considerable learning. He left a Spanish translation of the *Ethics of Aristotle*, a chronicle of the kings of Navarre, and several poems.

CHARLES, or CHARLES LOUIS (1771-1847), archduke of Austria, was the third son of the Emperor Leopold II. He commenced active service against the French at the age of twenty-two, and so distinguished himself that at twenty-five he was intrusted with the supreme command of the army of the Rhine. He defeated Jourdan at Teiningen, Amberg, and Würzburg, and Moreau at Rastadt; and the year after (1797) he was honoured with the command against Napoleon in Italy. In a month, however, peace was concluded; but the war soon recommenced, and in 1799 Charles defeated Jourdan once

more in Swabia, and then checked Masséna in Switzerland. After this he was forced by ill-health to retire from service. He was appointed governor of Bohemia; but it was not long before he had again to oppose his old enemy Moreau, with whom he made terms which were afterwards taken as the basis of the peace of Lunéville. His popularity was now such that the Diet of Ratisbon, which met in 1802, resolved to erect a statue in his honour, and to give him the title of Saviour of his Country; but Charles refused both distinctions. He was for some time president of the council of war, but in 1805 he was once more in Italy, where he won the victory of Caldiero over Masséna. On his return to Austria he became commander-in-chief and again president of the aulic council of war. He employed his time in organizing the army and establishing a strong reserve force, till in 1809 he took the field against the French army commanded by Napoleon in person. He carried on the conflict for five days, and fought with great gallantry; but at last, being wounded and overpowered, he retreated in good order. At the end of the campaign he gave up all his military offices, and spent the rest of his life in retirement, with the exception of a short time, when on the return of Napoleon from Elba, he became governor of Mayence. He published *Grundsätze der Strategie* (1814), and *Geschichte des Feldzugs von 1799 in Deutschland und der Schweiz* (1819).

CHARLES, the Bold (1433-1477), duke of Burgundy, born in 1433, was the son of Philip the Good of Burgundy and Isabella of Portugal. Remarkable both for his personal qualities and also for his position as the leader of the last great struggle of the feudal lords against royalty in France, and as the life-long enemy of crafty Louis XI., Charles was the last great figure of the Middle Ages. His physical strength and energy were extraordinary. He was full of the most lofty ambition, and capable of the most obstinate determination. He never forgot an injury. His passion was terrible and frequent. His boldness amounted to the rashness of fury. He was careless of luxury, though, in imitation of the ancient conquerors about whom he loved to read, he delighted to surround himself with magnificent display; and he presented an example of conjugal fidelity most remarkable in the society in which he lived.

As Charles rose to manhood, he found his father under the control of the Croys, whose usurpation of what he regarded as his own rightful function he deeply resented; and he allowed himself to be banished rather than take one of the family into his household. Soon after—he was at this time count of Charolais—he joined the duke of Brittany in forming a great confederation of the French nobles against King Louis. The confederates, calling themselves the League of the Public Weal, declared that their object was to get rid of bad ministers, to abolish taxes, and relieve the people from oppression. They maintained good discipline, paid for all they consumed, and consequently were opposed neither by the townsmen nor by the country-folk, while the gentry with their dependants flocked to their standard. In 1465 Charles met the royal army in the battle of Montlhéry, which was decided by the retreat of the latter during the following night. Paris was besieged; and Louis was forced to surrender Normandy to the duke of Berry, the towns on the Somme and the counties of Boulogne and Guienne to the count of Charolais, and other territory to other of the nobles. Charles's next exploit was the conquest of Liège, which, hitherto ruled democratically under the constitutional control of its bishop, was now struggling against the encroachments of Burgundy. The town of Dinant alone he excepted from the peace which he granted to the rest of the principality; and a year later he returned to take ven-

geance upon it. Its crime was that some of its apprentices had insulted himself and his mother by burning him in effigy as a bastard, and its punishment was an extravagant revenge. It was burned to the ground; of its men numbers were butchered, and the rest remained the unfortunate prisoners of the rude soldiery. The women were spared to be exposed to the extremes of cold and hunger, but were saved from worse treatment by the stern regard for female honour, which was Charles's most admirable characteristic.

At the age of thirty-four (1467) Charles became duke of Burgundy. Immense changes were at once effected. He permitted none of the gay festivity and wasteful profusion which had been common in his father's time, but the court was directed with a stately and splendid ceremony, in which the duke took his full share. Everything was arranged, though liberally, yet with strict order and economy; the state of the finances was carefully examined, and the amount in the treasury was largely increased by unusual demands from the Estates. Every petitioner, however humble, was heard; the duke shirked no details of business, was present at every council, and sharply rebuked or punished with a fine any absence or inattention on the part of the courtiers. A strict system of administering justice was instituted, and the law was carried out impartially even in the case of the most popular of the nobles.

Soon after his accession Charles increased his political influence by taking as his second wife Margaret the sister of Edward IV. of England. It was not long before he required all his power; for soon Louis again took possession of Normandy, and contrived to detach the duke of Brittany from his alliance with Burgundy. But Charles at once made ready for war, and the king in alarm took the daring step of requesting a meeting, and placing himself in the duke's hands at Peronne. Unfortunately for Louis, he had been for some time inciting the people of Liège to rebellion, and they chose this moment for an outbreak. Charles was mad with indignation, and with great difficulty restrained himself from taking vengeance upon the person of the king. After three days of irrepressible passion his wrath was so far spent that he contented himself with requiring Louis to undergo the ignominy of witnessing the punishment of the revolt which he had himself instigated, and with extracting from him a treaty, which, among other most important concessions, confirmed to the duke the possession of the territory which he then held, sanctioned the alliance with England, and took away the right of appeal from the courts of Flanders to the Parliament of Paris. In case of violation of this compact, the king invoked upon himself the curse of excommunication and the loss of the fealty of Burgundy; and a letter, signed by Louis, was despatched to each of the princes of the blood, requiring them in that event to take up arms against him.

Soon after this Liège was burned, like Dinant, and its inhabitants nearly exterminated, the fighting-men being mostly butchered, and the aged, the women, and the children exposed to the terrible cold; and the powerful city of Ghent, whose mob had forced from the duke the abolition of the hated cueillote and certain other concessions during his passage through the city before his coronation, was fain to avert his anger by giving up all, and allowing its charter to be annulled.

Charles had now reached the height of his power, but his greatness was unsubstantial. His subjects were becoming much estranged from him. The placid trade-loving Netherlanders found it hard to bear his arbitrary and haughty passion. The courtiers became weary of the stiff ceremonial of the court and the constant toil they were

obliged to undergo. Comines (seeing, as he tells us, that his master was madly rushing to destruction, but, as we can perceive, also affected by the promises of Louis) went over to the court of France. The king was now bold enough to reverse his hypocritical policy, and deny the validity of the treaty which he had signed under constraint at Peronne; and the towns on the Somme, never loyal to Burgundy, were reattached to France. The consequent war was, however, carried on by Charles with his usual success and his usual extravagance of severity.

His ambition and his policy were now changed. He cared no longer to make the lords independent of the king, but aimed at erecting a kingdom with himself as independent sovereign. Circumstances enabled him to obtain the reversion of Gueldres; and he entered into negotiations with the Emperor Frederick, to whose son he agreed to marry his daughter on condition that he should himself be elected king of the Romans. The emperor proposed instead to crown him king of Burgundy. A meeting, enlivened by a protracted round of gorgeous jousts and feasts, was held at Trêves (1473), in order to carry out the latter proposal; but the electors made a protest to Frederick, who was not remarkable for decision, and persuaded him to flee secretly by night.

In 1469 Sigismund, duke of Austria, being in great financial difficulty, had sold Alsace to Charles. The governor appointed by the latter was Peter von Hagenbach. His boldness as a soldier, his rough shrewdness, and his capacity for strong government had recommended him; but horrible stories were told of his brutality, his licence, and his blasphemies. He did indeed terrify the country into order, but his severity at length excited people and nobles alike against him, and he was tortured and condemned to death by a court of deputies, representing the Alsatian towns, with Bern, and one or two others. Charles did not fail to take signal vengeance, and the country was given up to indiscriminate slaughter and devastation. But he was now surrounded by powerful and determined enemies. He had himself refused to renew the treaty with Louis, who had on his part purchased the alliance of the Swiss. Sigismund of Austria, now desirous of redeeming Alsace, but having no objection to save his money, had been concerned in the rebellion of that province, and afterwards openly joined the French. But, notwithstanding all this, and in spite of the prohibitions and threats of the emperor, Charles prepared for the invasion of Cologne, in support of its bishop-ruler, by whose means he expected to bring the city under his own control. As a preliminary he attacked the strong town of Neuss. For eleven months it appeared that nothing could tear him from the siege. The Swiss routed his army, and ravaged Franche-Comté; the French army laid waste his territory and pillaged his towns; the emperor opposed him with a large force; the Pope commanded him to desist. At length he came to an understanding with the emperor. Neuss was put under a papal legate, and the fate of Cologne was left in the hands of the Holy Father (June 1475).

Immediately after this the English landed at Calais, but only to sign a treaty of peace with Louis at Picquigny. Yet Charles did not give up heart; and an important acquisition was made in the conquest of Lorraine. Again the Swiss took the aggressive, and possessed themselves of the Pays de Vaud. Notwithstanding his capture of Grandson, Charles was plainly overmatched; and, in 1476, he was utterly routed by them at Morat with immense slaughter. Still with no thought of yielding, he devoted himself with all his energy to raise and organize a fresh army. In a few months he was once more ready for war. René had meanwhile recovered Nancy; but

soon, through the cowardice of the Alsations, he was deserted, and his capital was invested by Charles. But René's triumph was at hand. The assistance of the Swiss was gained, and the Burgundians were attacked by an enemy they could not resist. On the 5th of January 1477 the battle took place. The Burgundians were scattered, and next day the massive body of Charles the Bold was found in a ditch, mutilated by several deadly wounds. It was buried at Nancy, but in 1550 his remains were removed to Bruges by Charles V.

See Comines, *Mémoires*; De Barante, *Histoire des ducs de Bourgogne*; J. Foster Kirk, *Charles the Bold*. (T. M. W.)

CHARLES ALBERT (1798-1849), king of Sardinia, was the son of Charles Emmanuel of Savoy Carignano. In his youth Charles became attached to the national party in Italy, and even formed a connection with the Carbonari. In 1821 Victor Emmanuel, on his abdication, appointed him regent; and he now availed himself of the opportunity for carrying out a liberal policy. He confirmed the constitution which had lately been established on the model of the new Spanish constitution, and which consisted of an assembly of one chamber, with a king deprived of the right of veto and of almost all real power. The approach of the Austrians, however, and the declaration of the new king, Charles Felix, refusing to recognize his acts, caused him to flee secretly from Turin after holding the regency little more than a week, and he was afterwards forbidden to enter the Sardinian court. In 1823 he served as a volunteer in the French army which invaded Spain in order to overthrow its new constitution; and by thus deserting his principles he obtained permission to return to Turin. He was for a few months, in 1829, viceroy of Sardinia; and in 1831 he succeeded Charles Felix on the throne. He felt obliged to resort to severe measures in order to secure his throne against the secret societies, of which the chief at that time was the society of "Young Italy," which had been founded by Mazzini. In 1847 risings took place in Sicily, Rome, Tuscany, and Naples; the Austrians were expelled from Milan, and the people of Piedmont gained the re-establishment of the constitution which Charles had advocated in his youth. At the same time Charles greatly increased the freedom of the press. During the next year he marched against the Austrians, who had already been broken by defeat, and who at once retreated. On the last day of April 1848 he won the victory of Pastrengo, and in the end of May, that of Goito. But two months after he was defeated at Custozza by Marshal Radetsky, and forced to retire to Milan, where he made an armistice with the Austrians, and, contrary to his promise, surrendered the city. On the expiration of the truce Charles again took up arms. A battle ensued with Radetsky at Novara, in which the Piedmontese army was rapidly and completely routed, though the king risked his life bravely, and some thought even desperately. An armistice was again sought, but the terms offered by Austria were such that Charles abdicated in favour of his son Victor Emmanuel II. He died four months later, on 28th July 1849. Charles did what he could to further commerce and to popularize art and science, and appears, notwithstanding apparent inconsistencies, to have sincerely desired the good of his people.

CHARLES AUGUSTUS (1757-1828), grand-duke of Saxe-Weimar, having been early deprived of his father, was educated under the governorship of Count Görtz, and among his tutors were Wieland, Knebel, Seidler, and Hermann. At seventeen he commenced his friendship with Goethe, who afterwards joined Schiller, Wieland, and Herder in forming the company of men of genius that distinguished his court. Charles assumed the direction of the government at the age of eighteen; and in the next year

entered the Prussian army, in which he remained till after the defeat at Jena (1806), when he became a member of the Rhenish confederacy, and furnished aid to the French. In 1813, he joined the coalition against Napoleon, and took the command of an army of Saxons, Hessians, and Russians. He fought among the Allies in 1815; and at the Congress of Vienna he received as reward for his services the enlargement of his principality, and its erection into a grand-duchy. Charles died in 1828. His correspondence with Goethe was published in 1863 at Leipsic.

CHARLES EDWARD, or, in full, CHARLES EDWARD LOUIS PHILIP CASIMIR (1720–1788), was born on the 31st December 1720. He was the elder son of James, known as the Pretender and the Chevalier St George. Grandson of James II. and nephew of Anne, he was heir of line of both these sovereigns; but the hereditary rights of his father and himself had been declared null under the Proclamation of Rights and other parliamentary enactments which followed and completed the Revolution of 1688.

The young prince was educated at Rome, his mother, by blood a Sobieski, superintending his studies for some years. On the whole his education was good; he became conversant with the French, Italian, and Latin languages, and his religious training was watched with interest by the Pope. His father's miniature court was frequented by English and Scottish noblemen of Jacobite sympathies, by foreign enemies of the house of Hanover, and by bigoted supporters of the Romish faith; and the influence of this society is distinctly evident upon his after life. In 1734, the duke of Liria, afterwards duke of Berwick, who was proceeding to join Don Carlos in his struggle for the crown of Naples, passed through Rome. He offered to the Pretender to take charge of his son, should Charles be willing to accompany him in his expedition. This offer was accepted, and the youth of fourteen, having been appointed general of artillery by Don Carlos, shared with credit the dangers of the successful siege of Gaeta.

The handsome and accomplished youth, whose doings were eagerly reported by the English ambassador, was now introduced by his father and the Pope to the highest Italian society, which he fascinated by the frankness of his manner and the grace and dignity of his bearing. To these, more than to any power of his mind or heroism of his career, are to be attributed the successes of his early life. James despatched his son on a tour through the chief Italian cities, that his education as a prince and man of the world might be completed. The distinction with which he was received on his journey, the royal honours paid to him in Venice, and the jealous interference of the English ambassador in regard to his reception by the Grand Duke of Tuscany, show how great was the respect in which the exiled house was held by foreign Catholic powers, as well as the watchful policy of England in regard to its fortunes.

The Pretender himself calculated upon foreign aid in his attempts to restore the monarchy of the Stuarts; and the idea of rebellion unassisted by invasion or by support of any kind from abroad was one which it was left for Charles Edward to endeavour to realize. Of all the European nations France was the one on which Jacobite hopes mainly rested, and the keen sympathy which Cardinal Tenein, who had succeeded Fleury as French minister of war, felt for the Pretender resulted in a definite arrangement for an invasion of England to be timed simultaneously with a pre-arranged Scottish rebellion. Charles was secretly despatched to Paris. A squadron under Admiral Roquefeuille sailed from the coast of France. Transports containing 7000 troops, to be led by Marshal Saxe, accompanied by the young prince, set sail for England. The sight of the English fleet and a severe storm effected, however, a complete disaster without any actual engagement

having taken place. The loss in ships of the line, in transports, and in lives was a crushing blow to the hopes of Charles, who remained in France in a retirement which he keenly felt, and which he resolved to quit by a personal visit to Scotland.

He had at Rome made the acquaintance of Lord Elcho and of Murray of Broughton; at Paris he had seen many supporters of the Stuart cause; he was aware that in every European court the Jacobites were represented in earnest intrigue; and he had now taken a considerable share in correspondence and other actual work connected with the promotion of his own and his father's interests. Although dissuaded by every friend he had, he, on 13th July 1745, sailed for Scotland on board the small brig "La Doutelle," which was accompanied by a French man-of-war, "The Elizabeth," laden with arms and ammunition. "The Elizabeth" fell in with an English man-of-war and had to return to France, while Charles escaped during the engagement, and at length arrived on the 2d of August off Eriska, a little island of the Hebrides. Receiving, however, but a cool reception from Macdonald of Boisdale, he set sail again and arrived at the bay of Lochnahuagh, on the west coast of Inverness-shire.

The Macdonalds of Clanranald and Kinloch Moidart, along with other chieftains, again attempted to dissuade him from the rashness of an unaided rising, but they yielded at last to the enthusiasm of his manner, and Charles landed on Scottish soil in the company of the "Seven Men of Moidart," who had come with him from France. Everywhere, however, he met with discouragement among the chiefs, whose adherence he wished to secure; but at last, by enlisting the support of Cameron of Lochiel, he gained a footing for more than a miniature rebellion. With secrecy and speed communications were entered into with the known leaders of the Highland tribes, and on the 19th of August, in the valley of Glenfinnan, the standard of James III. and VIII. was raised in the midst of a motley but increasing crowd.

On the same day Sir John Cope, at the head of 1500 men, left Edinburgh in search of Charles; but, fearing an attack in the Pass of the Corryarrick, he changed his proposed route to Inverness, and Charles thus had the undefended south country before him. In the beginning of September he entered Perth, having gained numerous accessions to his forces on his march. Passing through Dunblane, Stirling, Falkirk, and Linlithgow he arrived within a few miles of the astonished metropolis, and on the 16th of September a body of his skirmishers defeated the dragoons of Colonel Gardiner in what was known as the "Canter of Coltbrig." His success was still further augmented by his being enabled to enter the city, a few of Cameron's Highlanders having on the following morning, by a happy ruse, secured the Netherbow Port. On the 18th he occupied Holyrood.

Cope had by this time brought his disappointed forces by sea to Dunbar. On the 20th Charles met and defeated him at Prestonpans, and returned to prosecute the siege of Edinburgh Castle, which, however, he raised on General Guest's threatening to lay the city in ruins. In the beginning of November Charles left Edinburgh never to return. He was at the head of at least 6000 men; but the ranks were speedily thinned by the desertion of Highlanders, whose experience had led them to consider war merely as a raid and an immediate return with plunder. Having passed through Kelso, he, on the 9th November, laid siege to Carlisle, which capitulated in a week. On the 4th of December he had reached Derby and was within two days' march of London, whose inhabitants were terror-struck, and where a commercial panic immediately ensued. Two armies under English leadership were now in the field

against him,—the one under Marshal Wade, whom he had evaded by entering England from the west, and the other under the duke of Cumberland, who had returned from the Continent. London was not to be supposed helpless in such an emergency; Manchester, Glasgow, and Dumfries, rid of his presence, had risen against him, and Charles paused. There was division among his advisers and desertion among his men, and on the 6th of December he commenced his retreat.

Closely pursued by Cumberland, he marched across the border, and at last stopped to lay siege to Stirling. At Falkirk, on the 17th of January 1746, he defeated General Hawley, who had marched from Edinburgh to intercept his retreat. A fortnight later, however, Charles raised the siege of Stirling, and after a weary though successful march, rested his troops at Inverness. Having taken Forts George and Augustus, and had varying success against the supporters of the Government in the north, he at last prepared to face the duke of Cumberland, who had passed the early spring at Aberdeen. On the 8th of April the duke marched thence to meet Charles, whose little army, exhausted with a futile night march, half-starving, and broken by desertion, he engaged at Culloden on 16th April 1746. The decisive and cruel defeat sealed the fate of Charles Edward and the house of Stuart.

Charles fled. Accompanied by the faithful Ned Burke, and a few other followers, he gained the western coast. Hunted hither and thither, the prince wandered on foot or cruised restlessly in open boats among the many islands of the west. The barren Benbecula sheltered him for a month. In lack of food, unsightly in appearance, having a strange contentment under his misfortunes, and already betraying his weakness for liquor, Charles, upon whose head a price of £30,000 had a year before been set, was relentlessly pursued by the spies of the Government. Disguised in women's clothes, and aided by a passport obtained by the devoted Flora MacDonald, he passed through Skye, and parted from his conductress at Portree. Shortly afterwards he was again on the mainland, and in the end of July he took refuge with the "Seven men of Glenmoriston," a body of outlawed Jacobite freebooters, with whom for a time he was safe. Having joined Lochiel and Cluny Macpherson, he at last heard that two French ships were in waiting for him at the place of his first arrival in Scotland—Lochnaugh.

He embarked with speed, and sailed for France. Ere long he was again intriguing in Paris, and even in Madrid. So far as political assistance went his efforts were in vain; and he plunged eagerly into the gaieties of Parisian society, of which he was the hero for some years.

The enmity of the English Government to Charles Edward made peace with France an impossibility, so long as she continued to harbour the young prince. A condition of the treaty of Aix-la-Chapelle, concluded in October 1748, was that every member of the house of Stuart should be expelled the French dominions. Charles had forestalled the proclamation of the treaty by an indignant protest against its injustice, and a declaration that he would not be bound by its provisions. But his indignation and persistent refusal to comply with the request that he should voluntarily leave France had to be met at last with force; he was apprehended, imprisoned for a week at Vincennes, and on the 17th December conducted to the French border. He lingered at Avignon; but the French, compelled to hard measures by the English, refused to be satisfied; and the Pope, under threat of a bombardment of Civita Vecchia, advised the prince to withdraw. Charles simply and quietly disappeared; and for years Europe watched for him in vain. It is now established, almost with certainty, that he returned to the neighbourhood of

Paris; and it is supposed that his residence was known to the French ministers, who, however, firmly proclaimed their ignorance. In 1750, in 1752, and again, it is thought, in 1754, he was even in London, hatching futile plots, and risking his safety for his hopeless cause.

During the next ten years of his life Charles Edward had become a confirmed profligate. His illicit connection with a Miss Walkenshaw, whom he had first met at Bannockburn House while conducting the siege of Stirling, his imperious fretful temper, his drunken habits and debauched life, could no longer be concealed. He wandered over Europe in disguise, alienating the friends and crushing the hopes of his party; and in 1766, on the death of his father, he was treated even by the Pope with contempt, and his title as heir to the British throne was openly repudiated by the great powers.

It was in 1772 that France, still intriguing against England, arranged that Louise, Princess of Stollberg, should marry the besotted prince (now passing under the title of Count Albany) who twelve years before had so cruelly maltreated his paramour that she had left him for ever. Six years afterwards, however, the countess had to take refuge in a convent. Her husband's conduct was brutal, and her own life was in danger at his hands. Her suspected attachment to Alfieri the poet and the persistent complaints of the prince at last brought about a formal separation, and Charles Edward, lonely, ill, and evidently near death, remained at Florence. In remorse he wrote for his daughter, the child of Miss Walkenshaw, and she remained with him, under the name of duchess of Albany, during the last two years of his life. He died at Rome on the 31st of January 1788, and was buried in the *Grotte Vaticane* of St Peter's.

See Earl Stanhope's *The Forty-Five*, Chambers's *History of the Rebellion of 1745-6*, Burton's *History of Scotland*, Hayward's *Essays*, (vol. ii.), Ewald's *Life and Times of Charles Stuart*, The *Autobiography of Flora MacDonald*, &c.

CHARLES EMMANUEL I., The Great (1562-1630), duke of Savoy, succeeded his father Philibert Emmanuel in 1580. After having fought in alliance with Spain, France, and Germany, he laid claim to the throne of France on the death of Henry III. He became involved in war with Henry IV. and also with the Swiss, and was defeated at St Jorre in 1589. But the peace to which his defeat compelled him was soon broken, and he joined the Catholic league. He gained several successes, and obtained possession of Saluzzo, for which he had fought both with Henry III. and Henry IV. He next attacked Geneva, but without success; and his alliance with France against Spain was equally unfortunate, for Henry IV. dying, the regent made peace with Spain, and Charles was compelled to follow her example. After this he conquered Montferrat, which, however, he was unable to retain; and in 1619 he laid claim to the imperial crown without success. New leagues against Spain and against the Genoese followed. But finally the French conquered Savoy and part of Piedmont, and Charles died overwhelmed with misfortune.

CHARLES MARTEL (about 689-741), was an illegitimate son of Pepin d'Héristal, duke of Austrasia and mayor of the palace of the Merovingian kings of France. The wildness of Charles's youth, and most of all the suspicion that he was concerned in the murder of his brother, totally estranged the affection of his father, who left the mayoralty to one of his grandsons, and the regency to his wife. The Austrasians, however, unwilling to be ruled by an infant and a woman, made Charles their duke. His life was from that time one continual battle, of which the result was to lay the foundation of the modern French kingdom. He subdued the Neustrians, and made himself mayor of the palace; he forced the duke of Aquitaine to do

homage to the French crown; he drove back the Saxons, Bavarians, and other German tribes, who ravaged the frontier; and he compelled the Frisians to embrace Christianity. But by far his most important achievement was the victory which he won between Tours and Poitiers in 732, when he finally stayed the northward advance of the Saracens, and thus materially affected the subsequent course of European history. It is a commonly accepted tradition that it was his valour in this battle which gained him the title of Martel, or "the Hammer." In 737, on the death of Thierry IV., Charles did not go through the form of appointing another nominal king, though he never altered his own title. He divided his territory between his two sons, Pepin and Carloman, the former receiving Neustria, the latter Austrasia; and on the death of Carloman, Pepin gained possession of the whole kingdom, and assumed the title of king. Of the favour of the church Charles Martel was careless; he seized her lands to reward his warriors; and though he more than once defended the Pope, his name was execrated by the clergy, who were fond of painting him amid the torments of hell.

CHARLESTON, a city, a seaport, and the capital of Charleston county, South Carolina, United States, is situated in 32° 45' N. lat. and 79° 57' W. long. It stands upon a flat tongue of land pointing south-eastward between the Ashley and Cooper rivers, which here debouche into a spacious harbour extending about 7 miles south-east to the Atlantic, with an average width of two miles. The harbour is surrounded by land on all sides except the entrance, which is about one mile wide and 18 feet deep. The water in the harbour, however, is very much deeper, and the work of increasing the depth of the entrance is in progress. Fronting the Atlantic, and extending northwards, is Sullivan's Island, about six miles long; and on the other side of the entrance is Morris Island which stretches to the southward. Both islands are penetrated by channels. The harbour is well defended, —at its entrance by Forts Sumter and Moultrie, and inside by Castle Pinckney and Fort Ripley.

Owing to the lowness of the ground on which it is built, Charleston presents a peculiarly picturesque appearance from the harbour. Its spires and public buildings seem to rise out of the sea, while the richness of the surrounding foliage gives the place a particularly engaging aspect. Its proximity to the ocean tends materially to the equalization of the climate. In June 1874 the mean temperature in January was 52° 1', in June 81°, in July 79° 3', and in August 79° 1'. The maximum temperature (96°) occurred in June, and the minimum (27°) in January. The city covers an area of about five square miles, and has a water front of about nine miles. The streets are regularly laid out, and are generally well paved and lighted with gas. King Street and Meeting Street, the two chief avenues of the city, extend in nearly parallel lines, and are intersected by the shorter cross streets, which run between Ashley and Cooper rivers. There is little uniformity in the buildings, and there is a want of public squares and places; but many of the residences are surrounded with spacious ornamental grounds, which, with the numerous shade trees of all kinds, give the city a picturesque appearance. The most noted public buildings are the city orphan house, which has extensive grounds, the city hall, the custom-house, the arsenal, the court-house, and the Academy of Music, a theatre, which is esteemed one of the best in the southern States. The population of Charleston has increased from 18,711 in 1800 to 42,985 in 1850, to 40,519 in 1860, to 48,956 in 1870 (of whom 22,749 were coloured and 4892 foreigners), and to 56,540 in 1875 (of whom 32,012 were coloured).

Charleston is one of the leading commercial cities of the

South, being the outlet for a very rich rice and cotton producing country, and a point of supply for an extensive territory embracing South Carolina and parts of North Carolina, Georgia, Alabama, Florida, Tennessee, and Mississippi. The commerce consists chiefly of exports. During the year ending June 30, 1875, the foreign commerce comprised exports to the value of \$19,655,966, and imports valued at \$680,343. Included in the exports there were 265,410 bales of cotton, valued at \$18,709,949. Besides this foreign commerce there is an extensive trade in cotton, rice, naval stores, phosphate, and lumber, which are shipped in large quantities to ports of the United States. The extent of the commerce in these articles will be indicated by the following statement of the quantities received in Charleston from the interior for shipment for a series of years ending August 31:—

	1873.	1874.	1875.
Cotton, Upland.....bales	368,710	425,394	409,724
" Sea Island..... "	17,418	11,362	10,223
Rice.....tierces	48,943	43,667	46,796
Naval stores, spirits....casks	40,000	41,000	50,265
" resin.....lb	185,683	180,000	225,957
Phosphate, raw.....tons	49,838	56,413	51,546
" manufactured "	56,298	46,302	49,500
Timber.....feet	21,000,000	21,000,000	5,242,233

Of the total shipments of cotton during the year ending August 31, 1875, 264,305 bales were sent to foreign, and 154,869 to home ports. The large quantities of bone phosphate annually shipped are obtained in the vicinity of the city, where the richest deposits of this material in the United States have been discovered. A valuable fertilizer is manufactured from the phosphate. During the year ending June 30, 1875, 236 vessels, of 102,023 tons, entered in the foreign trade, and 268, of 119,274 tons, cleared; 504 vessels, of 382,018 tons, entered, and 461, of 328,266 tons, cleared in the coastwise trade. The number of vessels registered, enrolled, and licensed was 185, of 12,051 tons. The manufactures of Charleston are of inferior importance compared with its commerce. Among the most important industries are the manufacture of fertilizers from phosphate, in which more than \$2,000,000 is invested, and the preparation of rice for market by removing the husk, cleaning, &c. There are three rice mills in the city, where a large part of the rice crop of South Carolina and Georgia is cleaned. The manufacture of sulphuric acid is extensively carried on in connection with the phosphate industry. Charleston has an extensive wholesale trade in dry goods, boots and shoes, clothing, hats and caps, drugs and medicines, &c. The city has three national, four State, and five savings banks. Three railroads have their termini here,—the North-Eastern, extending to Florence; the South Carolina, to Augusta, Ga.; and the Savannah and Charleston. The Santee canal, 22 miles long, connects Charleston with the Santee River. The city is divided into eight wards, and is governed by a mayor and eighteen aldermen. It has an excellent fire department and an efficient police system. Among the public charitable institutions are the city orphan house, the catholic orphan asylum, the almshouse, the asylum for the aged and infirm, the city hospital, and the asylum for coloured orphans. In 1874 the school population was 12,727 of whom 3291 white and 2221 coloured children were attending the public schools. There were 75 teachers employed, of whom all were white, and all, except four, were females. The public schools are graded as primary, grammar, and high. There is also a normal school for girls. The higher institutions of learning are the College of Charleston, founded in 1785, which has a faculty of five and an excellent museum; and the Medical College of the

State of South Carolina, opened in 1832, which has a faculty of eight and a valuable pathological and anatomical museum. The Charleston library was founded in 1748, and has about 15,000 volumes. There are published in the city fifteen newspapers and periodicals—four daily, two thrice a week, four weekly, two fortnightly, two monthly, and one quarterly. The city contains 39 churches, the most noted edifices being St Michael's, built in 1752, and St Philip's, both Episcopal.

Charleston was founded about 1680 by English colonists who had come over with William Sayle. As early as 1670 they had settled a few miles distant from the site of the present city at a place which they named Charleston. The new village soon began to flourish, while the original settlement dwindled away and disappeared. During the revolutionary war two unsuccessful attempts were made by the British forces to take Charleston,—the first by Sir Peter Parker and Sir Henry Clinton in 1776, and the second by General Provost in 1779. After a siege of several weeks, the city was taken in May 1780 by a force under Sir Henry Clinton, but it was evacuated by the British in December 1782. In the recent civil war between the Northern and the Southern States Charleston was the scene of the first hostilities, which commenced April 12, 1861, with the bombardment of Fort Sumter by the Confederate General Beauregard. After the surrender of the Fort the Confederates took possession of the city, and held it until February 1865. In April 1863 a naval attack was made upon the fortifications in the harbour by a Federal fleet of nine iron-clads commanded by Admiral Du Pont. This effort, however, proved unsuccessful, as was also a land attack made by General Gillmore in July ensuing. The advance of General Sherman's army through South Carolina, and the fall of Columbia, the capital of the State, led to the evacuation of Charleston by the Confederates on the 17th of February 1865. The public buildings, cotton warehouses, stores, shipping, &c., had previously been fired by order of the general in command. From this and other causes the city suffered much injury during the war; but since its close many new buildings have been erected, and there has been marked commercial and industrial progress. (E. S. D.)

CHARLESTOWN, formerly a separate city of the United States, in Middlesex county, Massachusetts, but since 1874 incorporated with the city of Boston, with which it had long before been in many respects practically one. It was founded in 1628 or 1629, and soon rose into importance. The most remarkable event in its history is its almost complete destruction in 1775 during the revolutionary war. Its population in 1800 was 2751, which at the time of its incorporation with Boston had increased to 32,040. See BOSTON.

CHARLET, NICOLAS TOUSSAINT, a designer and painter, more especially of military subjects, was born in Paris on 20th December 1792, and died there on 30th October 1845. He was the son of a dragoon in the Republican army, whose death in the ranks left the widow and orphan in very poor circumstances. Madame Charlet, however, a woman of determined spirit and an extreme Napoleonist, managed to give her boy a moderate education at the Lycée Napoléon, and was repaid by his lifelong affection. His first employment was in a Parisian mairie, where he had to register recruits: he served in the National Guard in 1814, fought bravely at the Barrière de Clichy, and, being thus unacceptable to the Bourbon party, was dismissed from the mairie in 1816. He then, having from a very early age had a propensity for drawing, entered the atelier of the distinguished painter Baron Gros, and soon began issuing the first of those lithographed designs which eventually brought him renown. His Grenadier de

Waterloo, with the motto "La Garde meurt et ne se rend pas" (a famous phrase which has got attributed to Cambronne, but which he never uttered, and which cannot, perhaps, be traced farther than to this lithograph by Charlet), was particularly popular. It was only towards 1822, however, that he began to be successful in a professional sense. Lithographs (about 2000 altogether), water-colours, sepia-drawings, numerous oil sketches, and a few etchings followed one another rapidly; there were also three exhibited oil pictures, the first of which was especially admired—Episode in the Campaign of Russia (1836), the Passage of the Rhine by Moreau (1837), Wounded Soldiers Halting in a Ravine (1843). Besides the military subjects in which he peculiarly delighted, and which found an energetic response in the popular heart, and kept alive a feeling of regret for the recent past of the French nation and discontent with the present—a feeling which increased upon the artist himself towards the close of his career,—Charlet designed many subjects of town life and peasant life, the ways of children, &c., with much wit and whim in the descriptive mottoes. One of the most famous sets is the *Vie Civile, Politique, et Militaire du Caporal Valentin*, 50 lithographs, dating from 1838 to 1842. In 1838 his health began to fail, owing to an affection of the chest. Charlet was an uncommonly tall man, with an expressive face, bantering and good natured; his character corresponded, full of boyish fun and high spirits, with manly independence, and a vein of religious feeling, and he was a hearty favourite among his intimates, one of whom was the celebrated painter Géricault. Charlet married in 1824, and two sons survived him. A life of him was published in 1856 by a military friend, De la Combe.

CHARLEVILLE, a handsome and well-built town of France, on the left bank of the Meuse, in the department of Ardennes, about one mile north of Mézières, with which it is connected by a suspension bridge. Since the end of the 17th century it has become a thriving place, with manufactures of nails, hardware, and firearms, and an active export trade in wine, spirits, coal, iron, and slates. It has tribunals of primary instance and commerce, a commodious port, a theatre, a large public library, and a cabinet of natural history. The royal manufactory of arms formerly established here was transferred to Tulle and Châtelleraul. Charleville was founded by Charles of Gonzagua, eighth duke of Mantua, in 1606, and continued in the possession of his family till 1708. Its fortifications were dismantled in 1687; and in 1815 it was plundered by the Prussians. Louis Dufour, the abbé of Longuerue, was born in the town. Population in 1872, 12,059.

CHARLEVOIX, PIERRE FRANÇOIS XAVIER DE (1682-1761), a French Jesuit traveller and historian, was born at St Quentin in 1682. At the age of sixteen he entered the society of the Jesuits; and, at the age of twenty-three, was sent to Canada, where he remained for four years. He afterwards became professor of belles lettres at home; and travelled on the errands of his society in various countries. In 1720 he visited America for two years, in order to collect materials for his *Histoire de la Nouvelle-France*, which appeared in 1744. He also wrote *Histoire de Paraguay* (1756), *Histoire de Saint Domingue* (1730), *Histoire du Japon*, a compilation chiefly from Kamper (Rouen, 1715); and he was one of the directors of the *Journal de Trévoux*.

CHARLOTTENBURG, a town of Prussia, in the province of Brandenburg, district of Potsdam, and circle of Teltow, situated on the Spree, four miles west of Berlin, with which a fine promenade connects it. The town has well-built straight streets, two churches, and a free park; it has several spinning mills, oil and vitriol factories, a beer brewery,

and distilleries. It is much frequented in summer by visitors from Berlin. The castle, built in 1696 for the queen of Frederick I., the electress Sophia Charlotte, after whom the town was named, contains a collection of antiquities and paintings. In the castle grounds there is an extensive orangery, as also a granite mausoleum, the work of Schenkel, with monuments of Frederick William III. and Queen Louise by Rauch. The population in 1871 was 19,518.

CHARLOTTESVILLE, a town of the United States, the capital of Albemarle county, Virginia, situated about 65 miles north-west of Richmond on Moore's Creek, a tributary of Rivanna river. It is a railway junction of some importance; but its celebrity is due to the university of Virginia and the residence of Thomas Jefferson, which are both in the neighbourhood. The university was founded by Jefferson in 1819, and over \$200,000 was spent on the buildings; it is endowed and controlled by the state, and was attended in 1875 by 330 students. Monticello, the founder's residence, is still standing, though in a somewhat dilapidated state, and his tomb is to be seen in the family burying-ground. The population of the town in 1870 was 2838, of whom 1473 were coloured.

CHARLOTTE TOWN, a town of British America, in the Dominion of Canada, the capital of Prince Edward Island, is situated on gently rising ground on the north bank of Hillsborough River, at its junction with York River, not far from the south coast, in 14° 15' N. lat. and 63° 7' W. long. It has a good harbour in Hillsborough Bay, and the river is navigable by the largest vessels for several miles. Besides the Government buildings and the court-house, the town possesses an Episcopal, a Roman Catholic, and a Scotch church, a fort and barracks, a convent, a lunatic asylum, an exchange, a jail, three banks, and an almshouse; its educational institutions include the Prince of Wales College, supported by the province, the Roman Catholic College of St Dunstan's, the Wesleyan Methodist Academy, founded in 1871, and a normal school; and among its industrial establishments are an iron foundry, a woollen factory, and shipbuilding yards. Large quantities of grain are exported, as well as potatoes, fish, and pork. A steamer plies between the town and Southport every hour, and there is regular communication with several of the other continental ports. A railway, with a total length of 200 miles, runs east to Georgetown and Souris, and west to Somerside, Alberton, and Tignish. Population in 1871, 8807.

CHAROLLES, a town of France, the capital of an arrondissement in the department of Saône-et-Loire, 3 miles by rail W.N.W. of Mâcon. It has tribunals of primary instance and commerce, an agricultural society, a communal college, a public library, manufactories of potteryware, iron forges, and a considerable trade in corn, wine, cattle, and timber. It was the capital of Charolais, an old division of France, which from the 13th century gave the title of count to its possessors. In 1327 the countship passed by marriage to the house of Armagnac; and in 1390 it was sold to Philip of Burgundy. After the death of Charles the Bold, who in his youth had borne the title of count of Charolais, it was seized by Louis XI. of France; but in 1493 it was ceded by Charles VIII. to Maximilian of Austria, the representative of the Burgundian family. Ultimately passing to the Spanish kings, it became for a considerable period an object of dispute between France and Spain, until at length it was assigned to Condé the Great, in reward for the services he had rendered to the Spanish monarch. The ruins of the count's castle occupy the summit of a hill in the immediate vicinity of the town. Population in 1872, 3064.

CHARON, in Grecian mythology, the son of Erebus and Nox, whose office it was to ferry the souls of the deceased

who had received the rite of sepulture over the waters of Acheron. For this service each soul was required to pay an obolus or danace, one of which coins was accordingly placed in the mouth of every corpse previous to burial.

CHARONDAS, a celebrated lawgiver, who legislated not only for his native Catana, but likewise for various cities of Magna Græcia. By some he is said to have been a disciple of Pythagoras, who flourished 540-510 B.C.; and according to the common account (as given by Diodorus, XII.), he also drew up a code for the use of the Thurians; but this statement is scarcely admissible, since Thurii was not founded till the year 443, and it is known that the laws of Charondas were in use among the Rhegians till they were abolished by Anaxilaus, who reigned from 494-476 B.C. It is traditionally related that Charondas fell a sacrifice to one of his own laws, by which it was made a capital offence to appear armed in a public assembly. Hastening to quell a tumult on his return from a military expedition, his sword still hanging by his side, he was reminded by a citizen of his violation of the law, upon which Charondas exclaimed—"Then will I seal it with my blood!" and immediately plunged the weapon into his breast. Fragments of his laws are given in Heyne's *Opuscula*, vol. ii.

CHARPENTIER, FRANÇOIS (1620-1702), archæologist and man of letters, was born at Paris. Intended for the bar, he quitted law for literature at an early age, and was employed by the great minister Colbert, who had determined on the foundation of a French East India Company, to draw up an explanatory account of the project for the perusal of Louis XIV.; to the memoir he thus prepared he afterwards added a second part. Charpentier, who was an ardent admirer of his own tongue, was one of the first to demonstrate the absurdity of the use of Latin in monumental inscriptions, and to him was entrusted the task of supplying the paintings of Lebrun in the Versailles Gallery with appropriate legends. He acquitted himself so indifferently of the commission that his verses had to be replaced by others, the work of Racine and Boileau. With these poets Charpentier had already quarrelled, having espoused the cause of Perrault in the famous academical dispute (1687) concerning the relative merit of the ancients and moderns, and their notices of him are by no means calculated to place his abilities in the most favourable light. He is credited with an important share in the production of the magnificent series of medals that commemorate the principal events of the age of Louis Quatorze. Charpentier, who was long in receipt of a pension of 1200 livres from Colbert, was erudite and often ingenious, but he was always heavy and commonplace. His principal works are a *Vie de Socrate* (1650), a translation of the *Cyropædia* of Xenophon (1659), the *Traité de la Peinture Parlante* (1684), and the *Défense de l'Excellence de la Langue Française* (1695).

CHARRON PIERRE (1541-1603), a French philosopher, born in Paris in 1541, was one of the twenty-five children of a bookseller of that city. After studying law at Orleans and Bourges, and obtaining the degree of doctor from the latter university, he settled at Paris to practise as an advocate. But, having met with no great success during five or six years, he entered the church, and soon gained the highest popularity as a preacher, rising to the dignity of canon, and being appointed preacher in ordinary to Queen Margaret. At length, when about forty-seven years of age, he determined to fulfil a vow which he had once made to enter the cloister; but, being rejected by the Carthusians and by the Celestines, and having taken the advice of some professed casuists, he held himself absolved, and continued to follow his old profession. He delivered a course of sermons at Angers, and in the next year passed

to Bordeaux, where he formed his short but famous and important friendship with Montaigne. Its intimacy is shown by the fact that at the death of Montaigne, in 1592, Charron was requested in his will to bear the arms of his family.

In 1594 Charron published (at first anonymously, afterwards under the name of "Benedict Vaillant, Advocate of the Holy Faith," and also, in 1594, in his own name) *Les Trois Vérités*, in which, by methodical and orthodox argument, he seeks to prove that there is a God and a true religion, that the true religion is the Christian, and that the true church is the Roman Catholic. The last book (which is three-fourths of the whole work) is chiefly an answer to the famous Protestant work entitled *Le Traité de l'Église* by Du Plessis Mornay; and in the second edition (1595) there is an elaborate reply to an attack on the third *Vérité* which had been published anonymously by a Protestant writer. *Les Trois Vérités* gained considerable popularity, ran through several editions, and obtained for its author the favour of the bishop of Cahors, who appointed him grand vicar and theological canon. It also led to his being chosen deputy to the general assembly of the clergy, of which body he became chief secretary. It was followed in 1600 by *Discours Chrétiens*, a book of sermons, similar in tone, half of which treat of the Eucharist.

In the following year (1601) Charron published at Bordeaux his third and most remarkable work—the famous *De la Sagesse*, a complete popular system of moral philosophy. Usually, and so far correctly, it is coupled with the *Essays* of Montaigne, to which the author is under very extensive obligations; but though it is avowedly composed in great part of the thoughts and even the words of others, there is distinct individuality in the book. It is specially interesting from the time when it appeared, and the man by whom it was written. Conspicuous as a champion of orthodoxy against atheists, Jews, and Protestants—without resigning this position, and still upholding practical orthodoxy—Charron suddenly stood forth as the representative of the most complete intellectual scepticism.

His psychology is sensationalist. With sense all our knowledge commences, and into sense all may be resolved. The soul, located in the ventricles of the brain, is affected by the temperament of the individual; the dry temperament produces acute intelligence; the moist, memory; the hot, imagination. Dividing the intelligent soul into these three faculties, he shows—after the manner which Bacon subsequently adopted—what branches of science correspond with each. With regard to the nature of the soul he merely quotes opinions. The belief in its immortality, he says, is the most universal of beliefs, but the most feebly supported by reason. As to man's power of attaining truth his scepticism is decided; and he plainly declares that none of our faculties enable us to distinguish truth from error. In comparing man with the lower animals, Charron insists that there are no breaks in nature. "Those parts which approach and touch one another are more or less similar. So between man and the other animals there is much nearness and kindred." The latter have reason; nay, they have virtue; and, though inferior in some respects, in others they are superior. The estimate formed of man is not, indeed, flattering. His five most essential qualities are vanity, weakness, inconstancy, misery, presumption. Upon this view of human nature and the human lot Charron founds his moral system. Equally sceptical with Montaigne, and decidedly more cynical, he is distinguished by a deeper and sterner tone. Man comes into the world to endure; let him endure then, and that in silence. To be grieved by others' sorrows is a weakness; our compassion should be like that of God, who succours the suffering without sharing in their pain. Avoid vulgar errors;

cherish universal sympathy. Let no passion or attachment become too powerful for restraint. Follow the customs and laws which surround you. Such are the maxims he lays down.

Special interest attaches to Charron's treatment of religion. He has been lauded for his piety, and condemned for his infidelity; but he is justly to be regarded as a sceptic of the school of Montaigne. He insists on the diversities in religions; he dwells also on what would indicate a common origin. All grow from small beginnings and increase by a sort of popular contagion; all teach that God is to be appeased by prayers, presents, vows, but especially, and most irrationally, by human suffering. Each is said by its devotees to have been given by inspiration. In fact, however, a man is a Christian, Jew, or Mahometan, before he knows he is a man. One religion is built upon another; the Jewish, for instance, on the Egyptian and other Gentile religions, the Christian on the Jewish, the Mahometan on the Jewish and Christian combined. But while he openly declares religion to be "strange to common sense," the practical result at which Charron arrives is that one is not to sit in judgment on his faith, but to be "simple and obedient," and to allow himself to be led by public authority. This is one rule of wisdom with regard to religion; and another equally important is to avoid superstition. What superstition is he boldly ventures to define. It is the belief that God is like a hard judge who, eager to find fault, narrowly examines our slightest act, that He is revengeful and hard to appease, and that therefore He must be flattered and importuned, and won over by pain and sacrifice. True piety, which is the first of duties, is, on the other hand, the knowledge of God and of one's self, the latter knowledge being necessary to the former. It is the abasing of man, the exalting of God,—the belief that what He sends is all good, and that all the bad is from ourselves. It leads to spiritual worship; for external ceremony is merely for our advantage, not for His glory.

Charron's political views are neither original nor independent. He pours much hackneyed scorn on the common herd, declares the sovereign to be the source of law, and asserts that popular freedom is dangerous.

At once the *De la Sagesse* brought upon its author the most violent attacks, the chief being by the Jesuit Garasse. A second edition was nevertheless soon called for. In 1603, notwithstanding much opposition, it began to appear; but only a few pages had been printed when Charron died suddenly in the street. A summary and defence of the *Sagesse*, written shortly before his death, appeared in 1606. In 1604 his friend Michel de la Roche-mailliet prefixed to an edition of the *Sagesse* a *Life*, which depicts Charron as a man of the most amiable disposition and purest character. His complete works, with this *Life*, were published in 1635. An excellent abridgment of the *Sagesse* is given in Tennemann's *Philosophie*, vol. ix.

CHARTER. The word charter, from *χάρτης*, thick paper or parchment, came to be applied, from the substance on which it was written, to a document granted by a prince conferring or acknowledging privileges to be enjoyed by either the whole or a portion of the people under his rule. In England, from the Conquest downwards, there was a struggle between those who sought to enforce the feudal exactions which the Normans had learned in France and those who attempted to resist the innovation and hold to the old Saxon customs. If at first it was a contest between the monarch with his Norman followers on the one side and the Saxon population on the other, the conditions had changed during the lapse of nearly a century and a half preceding the reign of John, and the barons were so frequently incensed by the oppressions and exactions of the ambitious kings, to whose power they had contributed

so much, that they joined in the general demand for "the good old laws of Edward the Confessor." Even so early as the reign of the Conqueror himself, there was a royal acknowledgment of franchises or liberties, and the charters, renewals, or confirmations granted by subsequent kings are inextricably numerous. Coke, without exhausting them, counts thirty-two. The Great Charter of King John (1215) has so conspicuous a place in history, not only from its comparative completeness, but because it was exacted by men with arms in their hands from a resisting king, and was thus an enforced stipulation likely to be rigidly interpreted, instead of a concession carelessly conceded and readily forgotten. A great many of the stipulations of the Great Charter refer to feudal exactions now so long obsolete that the restraints on them cease to be intelligible; and those who have looked at the "palladium of our liberties," expecting to find in it high-sounding definitions of freedom like those in modern Continental declarations of right, have been much disappointed. Even in the comparatively popular language of Blackstone there is not much to convey a distinct expression to unprofessional modern readers.

"It fixed," he says, "the forfeiture of lands for felony in the same manner as it still remains, and prohibited for the future the grants of exclusive fisheries, and the erection of new bridges so as to oppress the neighbourhood. With respect to private rights, it established the testamentary power of the subject over part of his personal estate, the rest being distributed among his wife and children; it laid down the law of dower as it has continued ever since; and it prohibited the appeals of women, unless for the death of their husbands. In matters of public police and national concern, it enjoined a uniformity of weights and measures, gave new encouragements to commerce by the protection of merchant strangers, and forbade the alienation of lands in mortmain. With regard to the administration of justice, besides prohibiting all denials or delays of it, it fixed the court of common pleas at Westminster, that the suitors might no longer be harassed with following the king's person in all his progresses; and at the same time brought the trial of issues home to the very doors of the freeholders, by directing assizes to be taken in the proper counties, and establishing annual circuits. It also corrected some abuses then incident to the trials by wager of law and of battle, directed the regular awarding of inquests for life or member, prohibited the king's inferior ministers from holding pleas of the Crown, or trying any criminal charge, whereby many forfeitures might otherwise have unjustly accrued to the exchequer, and regulated the time and place of holding the inferior tribunals of justice, the county court, sheriff's turn, and court-leet. It confirmed and established the liberties of the city of London, and all other cities, boroughs, towns, and ports of the kingdom. And, lastly, it protected every individual of the nation in the free enjoyment of his life, his liberty, and his property, unless declared to be forfeited by the judgment of his peers or the law of the land."

The material feature of the document is that, so slightly referred to in the above extract, which says, "No freeman shall be taken or imprisoned, or be disseised of his freehold or liberties, or free customs, or be outlawed or exiled, or any otherwise damaged, nor will we pass upon him, nor send upon him, but by lawful judgment of his peers, or by the law of the land." In this stipulation there is inferred that supremacy of the fixed principles of the law over the will and power of the monarch, which has rendered the fanatical devotion of the English lawyers to their common law so justifiable; and as a farther security, the right of trial by peers or jurymen appointed a perpetual popular tribunal to check the official judges, should they be tempted to sell the liberties and privileges of the subject. Hallam, a very competent judge, says, "The institutions of positive law, the far more important changes which time has wrought in the order of society during 600 years subsequent to the Great Charter, have undoubtedly lessened its direct application to our present circumstances. But it is still the keystone of English liberty. All that has since been obtained is little more than a confirmation or commentary; and if every subsequent law were to be swept away, there would still remain the bold features that dis-

tinguish a free from a despotic monarchy."—(*Middle Ages*, chap. viii.)

Exemplars of the Great Charter were preserved among the muniments of cathedrals, and in other places calculated to preserve public archives. The Record Commission, when they published their edition of the statutes of the realm, were desirous to print the best authenticated version of the charter of King John; and they state, that "in Lincoln Cathedral, an original of the Great Charter of Liberties, granted by King John in the seventh year of his reign, is preserved in a perfect state. This charter appears to be of superior authority to either of the two charters of the same date preserved in the British Museum. From the contemporary indorsement of the word *Lincolina* on two folds of the charter, this may be presumed to be the charter transmitted by the hands of Hugh, the then bishop of Lincoln, who is one of the bishops named in the introductory clause."—(*Introduction*, xxix.)

Among the other concessions of a less comprehensive nature, the Charter of the Forest was deemed next in importance to Magna Charta. In nothing was the selfish rapacity of the Norman monarchs more conspicuous than in their relentless clearings of great districts of country for the establishment of forests or chases, where the sanctity of their field-sports was protected with a strict legal severity not conceded to the protection of ordinary property and personal freedom. The Charter of the Forest imposed wholesome limits on such inroads, and hence, along with the Great Charter, it has been printed at the commencement of the English statutes. The position of these documents in a series of Acts of Parliament is not so anomalous as it might seem; for it would be very difficult to distinguish the charters from the earliest statutes, which were concessions or admissions granted by the monarch on the requisition of the principal persons of the realm assembled together. Our statutes, indeed, still bear in their phraseology a testimony to this origin.

The early use of the word "charter," as a foundation of constitutional liberties, led to its being applied on various occasions to fundamental constitutional codes or rules of government adopted by various nations. The most memorable instance is the French *Charte*, containing the constitution of the French Government, as adjusted at the restoration in 1815, and amended at the revolution of 1830, which had its origin in an attempt of Charles X. to stretch one of its dubious clauses.

From such public acts as Magna Charta, the concession of privileges by charter from the Crown descended through various grades. Both in England and Scotland the privileges of municipal corporations either were conferred of old by charter, or were presumed to have been so conferred. The power of the Crown has in this form long virtually departed, but it is still competent to incorporate collective bodies with certain limited powers by royal charter; though, in general, it is deemed necessary when the powers might affect personal or public interests to secure them by Act of Parliament. Insidious privileges were sometimes granted by charter, and were among the objects of the attacks on the Crown's power to grant monopolies in the 17th century.

By the practice of mimicking the usages of the sovereign through all grades of fendality, it became the custom for every feudal lord or superior, high or low, when conceding any privilege as to his fief or landed property, to do so by a charter. Thus, throughout the British empire, and in Scotland especially, one of the most ordinary deeds connected with the commerce in land assumes to this day the shape of a concession of privileges by a sovereign or other high feudal lord to his vassal. One of the essential features which the student of Scottish law has to master in the

practice of conveyancing is the constitution of the charter. Although modern practice has ingrafted on it other classes of deeds, to suit the exigencies of the commerce in land, such as the disposition, the assignation, &c., yet "the charter" is the original source from which the spirit and tenor of the whole system of conveyancing are to be acquired.

CHARTER-PARTY, a written or partly written and partly printed contract, by which a ship is let or hired for the conveyance of goods on a specified voyage, or for a definite period. By the terms of this contract the owners declare the ship to be "tight, staunch, strong, and every way fitted for the voyage;" and they are accordingly liable in damages to the merchant or charterer, if the ship be unseaworthy, or if they fail to provide her with any necessary equipment or clearances. The shipowners are further bound to have the vessel ready to receive her cargo at the stipulated time; and they are responsible for the proper stowage of the goods received on board. On the loading being completed, the vessel must proceed without delay to her appointed destination; and should she unnecessarily deviate from the regular course of the voyage (a proceeding which might vitiate the merchant's insurances), the owners are liable in damages to the merchant. On arrival at the port of destination the goods are to be delivered "agreeably to bills of lading," the responsibility of the shipowners in this particular being limited by the usual exception against loss or damage by "the act of God, the queen's enemies, fire, and all and every other dangers and accidents of the seas, rivers, and navigation of whatever nature and kind soever." The freight payable to the shipowners is the amount specified in the charter-party, which may in certain cases be either more or less than the rates mentioned in the bills of lading,—the charterer having usually the right of sub-letting the ship in part or in whole to other shippers, on terms agreed upon between themselves, which it is customary to specify in their separate bills of lading, without prejudice to the original agreement. In such cases, however, the shipowners' lien on the goods for freight extends only to the amount specified in the bills of lading; and they must look to the charterer personally for any further sum which may be due to them.

The charterer, on his part, is bound to furnish the cargo at the port of loading, and to take delivery of the same at the port of discharge within specified periods, which are usually called "laydays." He may detain the vessel for a certain fixed time beyond the stipulated laydays on payment of a specified sum as "demurrage" for each day the ship is so detained. The laydays commence on the ship being ready to load or to discharge, even although it may happen from the port being crowded, or from similar causes, that she cannot at the time be placed in a berth where it would be convenient or practicable for the merchant to begin these operations.

The vessel is not bound to proceed nearer to her port of loading and discharging than "she may safely get;" and this generally means that she is not bound to go nearer to a loading port than to the point from which she can safely get away again with her cargo on board. The charterer, therefore, must pay the expense of necessary lighterage in loading or discharging, unless there be a specific agreement to the contrary.

It is usual to insert in charter-parties a clause by which the parties bind themselves to fulfil their contract under a specified sum as penalty for non-performance; but the amount of this penalty is not the absolute limit of the damages which either party may be entitled to recover under any of the other conditions which may have been violated. See CARRIER.

CHARTIER, ALAIN, the most distinguished French man of letters during the 15th century, was born at Bayeux.

The date of his birth is not known, but M. Vallet de Viriville places it between 1380 and 1390. After a complete course of study at the university of Paris, he is supposed to have entered the service of Charles VI., who is said to have charged him with important missions. After this, however, he is known to have followed the fortunes of Charles the Dauphin, afterwards Charles VII., and to have been employed by that prince, about 1420, in the triple capacity of clerk, notary, and financial secretary. He is also said to have held a prebend in the cathedral church of Notre-Dame de Paris, of which he was likewise arch-deacon, and to have been sent as envoy to the Scottish court. A Latin epitaph, discovered in the 18th century, and pronounced authentic by the biographer already cited, credits him with the enjoyment of other dignities than those referred to, and declares that he "*s'endormit enfin dans le Seigneur*," in the city of Avignon, "*l'an de l'Incarnation, 1449*."

There is some analogy between the fate of Alain Chartier and that of Ronsard. Both enjoyed an extraordinary reputation during their lives, and after death both were neglected and forgotten. Alain Chartier's lot was cast in troublous times—he felt the agony of Agincourt, and witnessed the rise of the Maid—but this would seem to have increased his renown. The story of the famous kiss bestowed by Margaret of Scotland, wife of that Louis the Dauphin who was afterwards to be known as Louis XI., on "*la précieuse bouche de laquelle sont issus et sortis tant de bons mots et vertueuses sentences*," authentic or not, is interesting, if only as a proof of the high degree of estimation in which the ugliest man of his day was held. Jean de Masles, who annotated a portion of his verse, has recorded how the pages and young gentlemen of that epoch were required daily to learn by heart passages of his *Bréviaire des Nobles*; Lydgate, the English rhymester, studied him ardently and affectionately; and Clément Marot and Octavien de Saint-Gélais, writing fifty years after his death, find many fair words for the old poet, their master and predecessor. For the last three centuries, however, Alain Chartier has been remembered rather on account of the kiss aforesaid than for the sake of any of the *bons mots* and *vertueuses sentences* that induced it. The Renaissance of 1830, even, that has made so many glories to blossom anew, has not justified again his old renown in the eyes of men. As a poet his fame has yielded to that of his contemporary, Charles of Orleans; and even his eloquent prose, which is said to be the best part of his work, has awakened no interest whatever. In spite of this, however, Alain Chartier deserves notice as one of the most remarkable and influential men of his time. His writings, both in prose and verse, breathe an ardent spirit of patriotism, and are notable, in some instances, for a boldness of thought and freedom of idea that seem to foreshadow the great utterances of the 16th century.

Alain Chartier, who is credited with the invention of the *rondeau déclinatif*, used all the forms of verse current at that period—roundel, lay, ballad, and complaint. His best books are said to be *Le livre des Quatre Dames*, which was called forth by the battle of Agincourt, and *Le Quadrilogue Inversif*, a fine patriotic dialogue, bearing date 1422. See Mancel, *Alain Chartier, étude bibliographique et littéraire*, 8vo., Paris, 1849.

CHARTISM was a movement for radical reform in English politics, which originated in 1838, reached its culminating point in 1848, and collapsed the same year; it took its name from the "People's Charter" or "National Charter," the document in which the scheme of reform was embodied. The Reform Bill of 1832 left a large class of the population, especially the working-men, dissatisfied. Accordingly, in 1838, after an unsuccessful attempt to initiate a scheme of more radical reform in the House of Commons, six of the most advanced members of the House had a consultation

with the deputies of the "Working-men's Association," the result being the appearance of the People's Charter, which embodied in the six following points the programme of their party:—(1) annual parliaments; (2) universal suffrage; (3) vote by ballot; (4) abolition of the property qualification for membership of the House of Commons; (5) payment of members; (6) equal electoral districts. The most influential of the six members of the House who took part in the drawing up of the charter was O'Connell, and the methods adopted for the propagation of their views were those practised by the great agitator with such success. Monster meetings were held, at which seditious language was occasionally spoken, and slight collisions with the military took place. Petitions of enormous size, signed in great part with fictitious names, were presented to Parliament; and a great many newspapers were started, of which the *Northern Star*, conducted by Feargus O'Connor, the active leader of the movement, had a circulation of 50,000. In 1840 the Chartist movement was still further organized by the inauguration at Manchester of the National Charter Association, which rapidly became powerful, being the head of about 400 sister societies, which are said to have numbered 40,000 members. Some time after, efforts were made towards a coalition with the more moderateradicals, but these failed; and a laud scheme was started by O'Connor, which prospered for a few years. In 1844 the fanatical spirit of some of the leaders was only too well illustrated by their attitude towards the Anti-Corn-Law League. O'Connor, especially, entered into a public controversy with Cobden and Bright, in which he was worsted; and he even endeavoured to defeat the purpose of the League. But it was not till 1848, during a season of great suffering among the working classes, and under the influence of the revolution at Paris, that the real strength of the Chartist movement was discovered, and the prevalent discontent became known. Early in March disturbances occurred in Glasgow which required the intervention of the military, while in the manufacturing districts all over the West of Scotland the operatives were ready to rise, in the event of the main movement succeeding. Some agitation, too, took place in Edinburgh and in Manchester, but of a milder nature; in fact, while there was a real and wide-spread discontent, men were indisposed to resort to decided measures. The principal scene of intended Chartist demonstration was London. An enormous gathering of half a million was announced for the 10th April on Kennington Common, from which they were to march on the Houses of Parliament to present a petition signed by nearly six million names, in order by this imposing display of numbers to secure the enactment of the six points. Probably some of the more violent members of the party thought to imitate the Parisian mob by taking power entirely into their own hands. The announcement of the procession excited great alarm, and the most decided measures were taken by the authorities to prevent a rising. The procession was forbidden. The military was called out under the command of the Duke of Wellington, and by him concealed near the bridges and other points where the procession might attempt to force its way. Even the Bank and other public buildings were put in a state of defence, and special constables, to the number, it is said, of 170,000, were enrolled, one of whom was destined shortly after to be the emperor of the French. After all these gigantic preparations on both sides the Chartist demonstration proved to be a very insignificant affair. Instead of half a million, only about 50,000 assembled on Kennington Common, and their leaders, Feargus O'Connor and Ernest Jones, shrank from the responsibility of braving the authorities by conducting the procession to the Houses of Parliament. The monster petition was duly presented, and scrutinized, with the result

that the number of signatures was found to have been grossly exaggerated, and that the most unheard of falsification of names had been resorted to. Thereafter the movement specially called Chartism soon died out. The return of national prosperity relieved the working classes of their most pressing grievances; and subsequent legislative changes have in great measure removed the causes that existed for discontent among the classes which mainly supported the charter.

CHARTRES, the chief town of the department of Eure-et-Loir, 55 miles south-west from Paris by railway, stands on a slope skirted by the River Eure, which flows partly within and partly beyond the ramparts. Its houses are antique and straggling; but there are four fine squares, in one of which, used as the herb-market, is an obelisk in memory of General Marceau, a native of the town. Chartres is the seat of a tribunal of the first instance, a tribunal of commerce, a communal college, and a diocesan seminary; and it has a weekly corn-market, which is one of the largest in France and is well managed by a corporation of women. Its chief manufactures are woollens and leather. Its cathedral of Notre Dame, a vast Gothic edifice, with two spires of different construction, is reckoned one of the finest cathedrals in France. It was founded in the 11th century by Bishop Fulbert on the site of an earlier church, destroyed by fire in 1020. In 1194 another conflagration laid waste the new building then hardly completed; but clergy and people set zealously to work, and the main part of the present structure was finished by 1240. Though there have been numerous minor additions and alterations since that time, the general character of the cathedral is unimpaired. The upper woodwork was consumed by fire in 1830, as well as the beautiful belfry of the old tower, but the rest of the building was saved; and it still preserves some of its magnificent stained-glass windows of the 13th century. (See Bulteau, *Descript. de la cathéd. de Chartres*, 1850.) The churches of St Pierre and St André may also be noticed.

Chartres was one of the principal towns of the Carnutes, and by the Romans was called Autricum, from the river Autura (Eure). From the Romans it passed into the hands of the Frankish kings, and was successively taken by Thierry II., king of Orleans and Burgundy, and by the Normans, who burnt it in 852 and 872. It afterwards fell into the hands of the English, from whom it was recovered in 1432. It was attacked unsuccessfully by the Protestants in 1563, and was taken in 1591 by Henry IV., who was consecrated there three years afterwards. In the Franco-Prussian War it was seized by the Germans on 21st Oct. 1870, and continued during the rest of the campaign an important centre of operations. During the Middle Ages it was the chief town of the district of Beauce, and gave its name to the counts of Chartres; and since the time of Louis XIII. the title of duke of Chartres has been hereditary in the family of Orleans. Population of the town in 1672, 13,322; and of the commune, 19,550.

CHARTREUSE, or more usually, to distinguish it from other establishments of the order, LA GRANDE CHARTREUSE, a famous Carthusian monastery of France, in the department of Isère, situated about 14 miles north of Grenoble, at a height of 4268 feet above the level of the sea, in one of the upper valleys of a group of calcareous mountains, near the sources of the Guiers Mort and the Guiers Vif, two tributaries of the Rhone. The settlement was originally founded in 1084, and derived its name from a small village a short distance to the south-east, which was formerly known simply as Chartreuse or *Cartusia*, but is now distinguished as Saint Pierre de Chartreuse. The first couvent on the present site was not erected till 1137, and most of the present edifice is of a later date than 1676. It stands in a large meadow, which slopes to the south-west, and is watered by a tiny tributary of the Guiers Mort; on the north a fine forest rises up to the Col of La Ruchère, while on the west the valley is shut in by well-wooded heights, and on the east is overshadowed by

the white ridges of Graudsom, which rise upwards of 2500 feet above the convent roof. All access to the spot was formerly by difficult and defensible pathways; and before the construction of the modern roads, it was very seldom that alien visitors disturbed the monks in their retreat. One of the principal approaches is by the valley of the Guiers Mort, which the traveller enters at St-Laurent-du-Pont, a village of about 1800 inhabitants, with a deaf-mute institution supported by the Carthusians. Passing up the left bank of the stream he next reaches the picturesque hamlet of Fourvoirie (Latin *forata via*), so named from the road which was driven up the pass at the suggestion of Le Roux, the thirty-third general of the order, in the 16th century. It is the seat of iron forges, a saw-mill, a farm, and laboratories belonging to the monks; and it was formerly the site of the first gateway that guarded the entrance to their domain. The river is there spanned by a noble three-storied bridge of a single arch; and about three miles higher up is the bridge of St Bruno, which has replaced the older Pérant bridge still hanging in romantic dilapidation over the torrent. A short distance higher up begins the new part of the road constructed by M. Eugène Viaud in 1853-4; it soon leads through the narrow passage of the Oillette or Aiguillette, formerly guarded by a second gateway, beyond which no female footstep was permitted; and after having passed through four separate tunnels, it brings the traveller in sight of the convent in about three hours from St-Laurent-du-Pont. Other routes of less interest are by the villages of Sappey and La Charmette. There is nothing very striking or beautiful about the architecture of the Chartreuse,—its principal features being the high roofs of dark slate and the cross-surmounted turrets. Within the buildings there are four halls for the reception of monks from the Carthusian provinces of France, Italy, Burgundy, and Germany, about sixty cells for the resident brethren, a church of the 15th and 16th centuries, several chapels, and a library, which before the Revolution contained a valuable collection both of books and manuscripts. A short distance from the main building is the infirmary, now set apart under the direction of the sisters of charity for the entertainment of female visitors. Since the revolutionary confiscation of 1793 the domain of Chartreuse has belonged to the state, and the monks, who were permitted to return to the monastery in 1816, pay a nominal rent for the use of the buildings and the right of pasturage, and have no longer any property in the neighbouring forests, which are in great measure due to their predecessors. Their revenue is augmented by the sale of various pharmaceutical preparations known as the Elixir, the Boule d'Acier (a mineral paste or salve), and the Chartreuse. In the manufacture of the last—a famous aromatic liqueur—caruations, absinthium, and the young buds of the pine tree are employed; there are three kinds—a green, a yellow, and a white—differing in degree of strength. The monks are distinguished by an active benevolence, the effects of which are visible in all the surrounding villages, where churches, schools, hospitals, and similar institutions have been erected and maintained at their expense. See BRUNO and CARTHUSIANS; also Adolphe Joanne's *Dauphiné et Savoie*, 1870, and Jules Taulier's *Guide du Voyageur à la Grande Chartreuse*, 1860.

CHARYBDIS. See SCYLLA and CHARYBDIS.

CHASE, SALMON PORTLAND (1808-1873), an American statesman, was born in Cornish, New Hampshire, on the 13th of January 1808. After graduating with distinction at Dartmouth College, at the age of eighteen he opened a classical school at Washington, and commenced the study of law under William Wirt. In 1830 he was admitted to the bar; and he soon after gained for himself considerable reputation by a compilation of the statutes of Ohio.

Throughout his whole career he was a consistent and vigorous opponent of slavery. From the first he was willing to risk his hopes of professional success by undertaking the defence of runaway slaves or of those who assisted their escape; and he boldly argued that slavery was merely an institution of the individual States, to which the national Government could not extend its sanction. He took a prominent part in the anti-slavery convention which met at Columbus in 1841, in the first "National Liberty Convention" of 1843, in the "Southern and Western Liberty Convention" of 1845, and in the second "National Liberty Convention" of 1847. He also presided over the "National Convention" of 1848, which nominated Van Buren for president and Adams for vice-president. In 1849 he became member of the senate; and in 1855 he was elected governor of Ohio, in which position he was so popular that he was re-elected, two years after, by an extraordinarily large number of votes. He was also three times nominated for the presidency, though he never attained that dignity.

On the accession of Lincoln to the presidency, in March 1861, Chase became secretary of the treasury; and he fulfilled the duties of this most important and difficult post with the greatest energy till June 1864. Still, notwithstanding his ability and zeal, it cannot be said that the measures he adopted were the best even in the extremely difficult circumstances in which he was placed. Though he appears to have apprehended some of the evil consequences likely to arise from the creation of inconvertible notes, he argues that their issue was necessary on the ground that it would increase the loanable capital of the country, while, in fact, employed as it was by Government in defraying expenses, it could have no such effect. At first Chase contemplated raising a large sum by direct taxation; but this course Congress refused to pursue. He was forced, therefore, to resort to a considerable increase of the taxes on imports, to issues of an inconvertible paper currency, and to enormous loans, which were contracted upon unnecessarily expensive terms. The interest was, in reality, about double its nominal amount, owing to the fact that it was paid in gold; and, beside this, a considerable loss was sustained through the arrangement by which the debt contracted in depreciated paper was discharged in coin.

It was under his management that Congress passed the Banking Law of February 1863, which, as amended in June 1864, is still in force (see BANKING, vol. iii. p. 310). It was at that time useful in two ways; for it procured for the Government, in its necessity, a considerable loan from the banks, and it replaced the notes of the banks, which had lost their credit through frequent failures, by notes which possessed the Government guarantee. Its great recommendation at present is that it secures the trustworthiness of the note currency.

In December of the year in which he resigned the secretaryship of the treasury, Chase was appointed Chief Justice of the Supreme Court of the United States, and in this capacity he had to undertake the responsibility of superintending the trial of President Johnson. But his health was now broken, and his old activity was no longer possible. In June 1870 he suffered a shock of apoplexy, and on May 7, 1873, he died at New York.

CHASTELAIN, GEORGES (1403-1475), called *L'Adventurer*, the celebrated Burgundian chronicler, was born at Alost in Flanders. When only seven years old he began the study of letters. This, however, he abandoned to become a soldier, serving first of all as a squire. Particularly favoured by Philip the Good, duke of Burgundy, he quitted the career of arms towards 1443, and devoted himself to the service of that prince, who made him successively pantler, orator, and finally grand chronicler of the house of

Burgundy. In addition to such duties as these offices entailed upon their holder, Chastelain was often employed diplomatically, and was also accustomed to direct the dramatic entertainments designed for the amusement of the ducal court. A heavy but insolent opusculum in verse, published by him in 1455, had nearly compromised his safety, as it was held to contain reflections injurious to the honour of the king and nobility of France; Chastelain, however, extricated himself from the difficulty by issuing a sort of reply (in prose) to his own libel. About this time, too, at the request of Philip, he began his most important work, the *Grande Chronique*. Philip's son, Charles the Bold, continued to confide in and favour Chastelain as his father had done, and conferred on him the order of the Golden Fleece, with the title of *Indiciaire*—a designation intended as descriptive of one who “démonstroît par escripture authentique les admirables gestes des chevaliers et confrères de l'ordre.” At the beginning of the new reign, however, Chastelain retired to Valenciennes, where he busied himself till his death in the production of his *Chronique* (in which he was assisted by Jean Molinet, his disciple and continuator) and of other works, imaginative and historical.

Among his contemporaries, Georges Chastelain acquired by his verses the style and title of a second Homer; but posterity, in relegating his poetry to eternal oblivion, has been careful of his memory. As an historian, Chastelain is deserving of more attention. He was a soldier and traveller, who had yet been trained to letters, the favourite of a splendid prince, and personally acquainted with most of the actors in the great scenes which his position enabled him to study on the very theatre of their action. His method of writing history, to judge by a declaration of his own yet extant, was not such as would have occurred to the mere compiler or writer from dictation. The vast mass of material collected during his long and busy life was intended to be fused and shaped as his own conclusions, his own great experience of men and years, should determine, and not altogether according to the requirements of party and feudal feeling. Impartiality, however, must not be considered one of his virtues. A brilliant satirist, and at the same time, a master of eulogy, it was his interest to use all his gift in his master's service, and he did so use it.

Only three fragments of the *Chronique*, which was to have filled six volumes, in folio are known to exist—the first extending from 1419 to 1422, and the second, with large breaks in the text, from 1461 to 1474. A third mutilated fragment is understood to refer to the period uncovered by the larger chapters, but it neither tells a connected story nor fills the great gap between the other two.

CHASTELARD, PIERRE BOSCOBEL DE (1540–1563), a French poet whose name is inseparably connected with that of Mary Queen of Scots, was born in Dauphiné, and was a scion of the house of Bayard. From the service of the Constable Montmorency, Chastelard, then a page, passed to the household of Marshal Damville, whom he accompanied in his journey to Scotland in escort of Mary (1561). He returned to Paris in the marshal's train, but left for Scotland again shortly afterward, bearing letters of recommendation to Mary from his old protector, Montmorency, and the *Régrets* addressed to the ex-queen of France by Pierre Ronsard, his master in the art of song. He is also understood to have undertaken the charge, for transmission to the poet, of the service of plate with which Mary rewarded him. But he had fallen in love with the queen, who is said to have encouraged his passion. Copies of verse passed between them; she lost no occasion of showing

herself partial to his person and conversation. The young man hid himself under her bed, where he was discovered by her maids of honour. Mary pardoned the offence, and the old familiar terms between them were resumed. Chastelard was so rash as again to violate her privacy. He was discovered a second time, seized, sentenced, and hanged the next morning. He met his fate valiantly and consistently, reading, on his way to the scaffold, his master's noble *Hymne de la Mort*—“Très-bien fait et propre pour ne point faire abhorrer la mort”—and turning at the instant of doom towards the palace of Holyrood, to address to his unseen mistress the famous farewell—“Adieu, toi si belle et si cruelle, qui me tues et que je ne puis cesser d'aimer.” This at least is the version of Brantôme, who is, however, as notoriously untrustworthy as an authority as he is charming as a writer. Another account is that the plaint was a reproach, contained in the exclamation “Cruelle reine!” and emphasized by a threatening gesture addressed to Mary's apartments.

Sworder and amorist, audacious and irreligious, with a strong sense of the nobility of art and some taste for its practice, Chastelard is a favourable specimen of the golden youth of the French Renaissance. As a poet he is not remarkable—merely one of “the mob of gentlemen who wrote with ease,” in spite of the notes of truth and passion occasionally to be distinguished through the clink and fall of his verse. But for his madness of love, indeed, it is possible that he would have left no shadow or shred of himself behind. As it is, however, his life and death are of interest as illustrating the wild days in which his lot was cast.

See Chalmers, *Life of Mary Queen of Scots*; Knox, *History of the Reformation*; Mignet, *Histoire de Marie Stuart*; Dargaud, *Histoire de Marie Stuart*; Le Laboureur, *Mémoires de Castelnau*; Brantôme, *Mémoires*. Mr Swinburne's tragedy of *Chastelard* is too well known to need more than passing reference.

CHATEAUBRIAND, FRANÇOIS RENÉ, VISCOUNT DE (1768–1848), the most brilliant representative of the reaction against the ideas of the French Revolution, and the most conspicuous figure in French literature during the First Empire, was born at St Malo, September 4, 1768. Here, as beautifully narrated by himself, his naturally poetical temperament was fostered by picturesque influences, the mysterious reserve of his morose father, the ardent piety of his mother, the traditions of his ancient family, the legends and antiquated customs of the sequestered Breton district, above all, the vagueness and solemnity of the neighbouring ocean. He received his education at Dol and Rennes, and after declining to enter the church from an absence of vocation, obtained a commission in the army when on the point of proceeding to try his fortune in India (1788).

His thirst for distinction, further excited by the political convulsions of the following year, found vent in a romantic scheme for the discovery of the North West Passage, in pursuance of which he departed for America in 1790. The passage was not found or even attempted, but the adventurer returned enriched with the to him more important discovery of his own powers and vocation, conscious of his marvellous faculty for the delineation of nature, and stored with ideas and imagery, the material of much of his future work. His return coincided with the execution of Louis XVI. Chateaubriand, a Breton and a soldier, could not do otherwise than throw himself into the ranks of the emigrants. After the failure of the duke of Brunswick's invasion he retired to England, where he lived obscurely for several years, gaining an intimate acquaintance with English literature, and elaborating *The Natchez*, a prose epic designed to portray the life of the Red Indian tribes, and inspired by reminiscences of his American travels. Two brilliant episodes of

this work, *Atala* and *René*, have acquired universal renown; but the work as a whole, to say nothing of the unreality of its pictures of savage life, belongs to that unfortunate compromise between the forms of prose and poetry in a manner imposed upon the French language by the penury of its poetic diction, but incapable of the perfection of either poetry or prose. Chateaubriand's first publication, however, was the *Essay on Revolutions* (1797). In this remarkable work, which the author subsequently retracted, but took care not to suppress, he appears as a mediator between royalist and revolutionary ideas, a free-thinker in religion, and in philosophy imbued with the spirit of Rousseau. A great change in his views was, however, at hand, induced, as he would have us believe, by the death of his mother in the same year. It is certain that upon his restoration to his country three years subsequently, the *Genius of Christianity* was already in an advanced state. Before publishing it, however, he determined to make an essay with an episode of his romance. *Atala*, or *The Loves of Two Savages*, appeared in 1801, and immediately raised the author to the summit of literary distinction. Exquisite style, impassioned eloquence, and glowing descriptions of nature, gained indulgence for the incongruity between the rudeness of the personages and the refinement of the sentiments, and for the distasteful blending of prudery with sensuousness; the latter was indeed conformable to the example of the author's models and predecessors. Alike in its merits and defects, the piece is a more emphatic and highly-coloured "Paul and Virginia;" it has been justly said that Bernardin Saint Pierre models in marble and Chateaubriand in bronze. Encouraged by his success, the author resumed his *Genius of Christianity*, which appeared in the following year, just upon the eve of Napoleon's re-establishment of the Catholic religion, for which it thus almost seemed to have prepared the way. No coincidence could have been more opportune, and Chateaubriand might almost be pardoned for esteeming himself the counterpart of Napoleon in the intellectual order, as he certainly did. In composing his work he had borne in mind the admonition of his friend Joubert, that the public would care very little for his erudition and very much for his eloquence. It is consequently an inefficient production from the point of view of serious argument. The considerations derived from natural theology are but commonplaces rendered dazzling by the magic of style; and the parallels between Christianity and antiquity, especially in arts and letters, are at best ingenious sophistries. The less polemical passages, however, where the author depicts the glories of the Catholic liturgy and its accessories, or expounds its symbolical significance, are splendid instances of the effect produced by the accumulation and judicious distribution of particulars gorgeous in the mass, and individually treated with the utmost refinement of detail. Taken altogether, the work is a masterpiece of literary art, and its immediate effect was very considerable. It admirably subserved the statecraft of Napoleon, who appointed the writer attaché at Rome, and when his insubordinate and intriguing spirit compelled his recall, transferred him as envoy to the canton of the Valais. The murder of the duke of Enghien took place during his absence on this mission. Chateaubriand, to his honour, immediately resigned his post, and subsequently manifested great courage in his indirect censures of Napoleon in a journal of which he had become proprietor, and which was ultimately suppressed. Ere this he had departed on a pilgrimage to Jerusalem, undertaken, as he subsequently acknowledged, less in a devotional spirit than in quest of new imagery, and in deference to the wishes of a lady friend. The journey produced (1811) a record of travel distinguished by his habitual picturesqueness, and

also inspired his prose epic of *The Martyrs*, published two years previously. This work may be regarded as the argument of the *Genius of Christianity* thrown into an objective form. Moore's *Epicurean*, and the more ambitious passages of Bulwer's earlier romances, may convey an adequate notion of it to the merely English reader. As in the *Epicurean*, the professed design is the contrast between Paganism and Christianity, which fails of its purpose partly from the absence of real insight into the genius of antiquity, and partly because the heathen are the most interesting characters after all. Two years previously had appeared *René*, another detached episode of *The Natchez*, and perhaps Chateaubriand's most characteristic production. The connecting links in European literature between *Werther* and *Childe Harold*, it paints with wonderful mastery the misery of a morbid and dissatisfied soul, the type of a character blighted by over-sensitiveness on the one hand, and an egotism thinly disguised by poetical sentiment on the other. The representation is mainly from the life, and Chateaubriand must certainly be acquitted of the unreality and affectation which so frequently characterize similar delineations of the poetic temperament. René's morbid despondency is but the too faithful portrait of the desolation begotten in his own mind by the unnatural alliance between opulence of imagination and poverty of heart. His sister Lucile is the Amélie of the story. *The Natchez*, of which *René* was to have formed an episode, was not published until 1826, at which time also appeared the beautiful tale of *The Last of the Abencerrages*, written about 1809, and, as the author asserts, withheld from publication on account of the Peninsular War. With this composition Chateaubriand's career as an imaginative writer is closed; and we have henceforth chiefly to consider him as a politician. His character in this point of view may be comprised in a sentence; he was equally formidable to his antagonists when in opposition and to his friends when in office. His poetical receptivity and impressionableness rendered him honestly inconsistent with himself, while his vanity and ambition, too morbidly acute to be restrained by the ties of party allegiance, made him dangerous and untrustworthy as a political associate. His pamphlet, *Bonaparte and the Bourbons*, published in 1814, while the fate of Napoleon yet trembled in the balance, was as opportune in the moment of its appearance as the *Genius of Christianity*, and produced a hardly less signal effect. Louis XVIII. declared that it had been worth a hundred thousand men to him. Chateaubriand was called to his councils, accompanied him to Ghent during the Hundred Days, and for a time associated himself with the excesses of the royalist reaction. Political bigotry, however, was not among his faults; he gradually drifted into liberalism and opposition, and upon a change of ministry, obtained the London embassy, from which he was transferred to represent his country at the Congress of Verona. He here made himself mainly responsible for the iniquitous invasion of Spain,—an expedition undertaken, as he himself admits, with the puerile idea of restoring French prestige by a military parade. He next received the portfolio of foreign affairs, which he soon lost by his desertion of his colleagues on the question of a reduction of the interest on the national debt. After another interlude of effective pamphleteering in opposition, he accepted the embassy to Rome under the Martignac administration, resigned it at Prince Polignac's accession to office, and on the downfall of the elder branch of the Bourbons, made one last extremely brilliant but inevitably fruitless protest from the tribune in defence of the principle of legitimacy. During the first half of Louis Philippe's reign he was still active with his pen, and was regarded as the most efficient champion of the exiled dynasty, but as years increased upon him, and the prospect

of his again performing a conspicuous part diminished, he relapsed into an attitude of complete discouragement, and contributed to chill the ardour of his own party. His narrative of his share in the Congress of Verona, the *Life of Rancé*, and his translation of Milton, belong to the writings of these later days. He expired on July 4, 1848, wholly exhausted and thoroughly discontented with himself and the world, but affectionately tended by his old friend Madame Récamier, herself deprived of sight. His remains were interred in Grand Bey, a lonely islet off the coast of Brittany. Shortly after his death his memory was powerfully revived, and at the same time exposed to much adverse criticism, by the publication, with sundry mutilations as has been suspected, of his celebrated *Mémoires d'Outre-Tombe*, the composition of which had occupied him at intervals during the greater part of his life. These memoirs undoubtedly reveal his vanity, his egotism, the frequent hollowness of his professed convictions, and his incapacity for sincere attachment, except, perhaps, in the case of Madame Récamier. They abound, on the other hand, with beauties of the first order, and much of the rough treatment they have experienced is attributable to the animosity of party. Their principal literary defect is the frequent encroachment of the historical element upon the autobiographical, the writer's exaggerated estimate of his own consequence leading him to allow a disproportionate space to transactions in which he had in fact but little share.

Chateaubriand ranks rather as a great rhetorician than as a great poet, rather as a great writer than a great man. Something of affectation or unreality commonly interferes with the enjoyment of his finest works. The *Genius of Christianity* is a brilliant piece of special pleading; *Atala* is marred by its unfaithfulness to the truth of uncivilized human nature, *René* by the perversion of sentiment which solicits sympathy for a character rather deserving of contempt. Chateaubriand's fame owes much to the timeliness of his appearances in print, and even more to the genuine conviction of his countrymen that French literature and European literature are practically convertible terms. They have hence made his position in the former the standard of his influence over the latter, which, for an author so widely read and so generally admired, has in reality been but small. Even in France he is chiefly significant as marking the transition from the old classical to the modern romantic school. He belongs to the latter by the idiosyncrasy of his genius, to the former by the comparative severity of his taste. The fertility of ideas, vehemence of expression, and luxury of natural description, which he shares with the romanticists, are controlled by a discipline imbibed in the school of their predecessors. His palette, always brilliant, is never gaudy; he is not merely a painter but an artist. He is a master of epigrammatic and incisive sayings, and has contributed as much as any great French writer to foster the disastrous national partiality for *la phrase*. Perhaps, however, the most truly characteristic feature of his genius is the peculiar magical touch which Mr Arnold has indicated as a note of Celtic extraction, which reveals some occult quality in a familiar object, or tinges it, one knows not how, with "the light that never was on sea or land." This incommunicable gift is of necessity genuine, and supplies an element of sincerity to Chateaubriand's writings which goes far to redeem the artificial effect of his calculated sophistry and set declamation. It is also fortunate for his fame that so large a part of his writings should directly or indirectly refer to himself, for on this theme he always writes well. Egotism was his master-passion, and beyond his intrepidity and the loftiness of his intellectual carriage his character presents little to admire. He is a signal instance of the compatibility of genuine

poetic emotion, and sympathy with the grander aspects both of man and nature, and even munificence in pecuniary matters, with absorption in self and general sterility of heart.

The principal authority for Chateaubriand's biography is his own *Mémoires d'Outre-Tombe*. The *Souvenirs et Correspondance* of Madame Récamier may also be consulted. The best general review of his character and writings is Sainte Beuve's *Chateaubriand et sa Groupe Littéraire*, Paris, 1872; see also the Count de Marcellus's *Chateaubriand et son Temps*, and for his diplomatic career the latter's *Souvenirs Diplomatiques*. The best edition of his works is Sainte Beuve's, Paris, 1859-60. (R. G.)

CHÂTEAUBRIANT, a town of France, at the head of an arrondissement in the department of Loire Inférieure, on the left bank of the Chère, a tributary of the Vilaine, 35 miles N.N.E. of Nantes. It takes its name from a castle founded in 1015 by Briant, count of Penthièvre; and its principal ornament is another castle, built in 1524 by Jean de Laval, and famous in history as the scene of the assassination of Françoise de Foix. There is also an interesting Romanesque church dedicated to St Jean de Bère. The manufactures are mainly woollen stuffs and confectionery; and the trade is in iron, coal, and wood. Population in 1872, 4134.

CHÂTEAUDUN, a town of France, capital formerly of the countship of Duuois, and now of an arrondissement in the department of Eure-et-Loir, 28 miles S.S.W. of Chartres. It stands on an eminence near the left bank of the Loir, and has remains of an old castle, several ancient churches, a town-hall, a communal college, a public library, and manufactures of woollens and leather. It was almost entirely destroyed by fire in 1723, and in 1870 it was captured by the Germans. Population in 1872, 5923.

CHÂTEAU-GONTIER, a town of France, at the head of an arrondissement in the department of Mayenne, on the right bank of the Mayenne river, here crossed by a stone bridge, 17 miles S.S.E. of Laval. It has a fine Gothic church, a communal college, three hospitals, an agricultural society, public baths, extensive bleach fields, and manufactures of linen and woollen stuffs. It is also the entrepôt of a great part of the trade of the department in wine, slate, iron, and coal. Château-Gontier owes its origin and its name to a castle erected in 1037 by Gunther, the steward of Fulques Nerra of Anjou, on the site of a farm belonging to the monks of St Aubin d'Angers. On the extinction of the family, the lordship was assigned by Louis XI. to Philippe de Comines. The town suffered severely during the wars of the League, and in the Vendean struggle it was the scene of sanguinary proceedings. Population in 1872, 7048.

CHÂTEAUROUX, a town of France, capital of the department of Indre, is situated in a fine plain on the left bank of the Indre, 90 miles by rail S.W. of Orleans. It is the seat of a court of assize, and tribunals of primary instance and commerce; and it has a castle, now used as the town-hall, a cathedral, erected about 1873, a society of arts and agriculture, a communal college, a theatre, and a public library. It is ill built, with narrow filthy streets. The principal manufacture is woollens, in which a great part of its inhabitants are employed; it has an active trade in woollen yarn, leather, iron, grain, and cattle, and there are quarries of lithographic stone in the neighbourhood. The castle from which it takes its name was founded about the middle of the 10th century by Raoul, prince of Déols, and passed into the possession of several noble families. In 1215 one of the earliest of the Franciscan monasteries was founded in the town by William of Chauvigny. Raised to the rank of a countship in 1497, and to that of duchy in 1616, it finally passed into the possession of Louis II. of Bourbon, prince of Condé, and the castle served for the incarceration of his wife for twenty-three years. General Bertrand was born in the castle in 1773, and his statue

adorns the Place Sainte Hélène. Population of the town in 1872, 16,858; of the commune, 18,670.

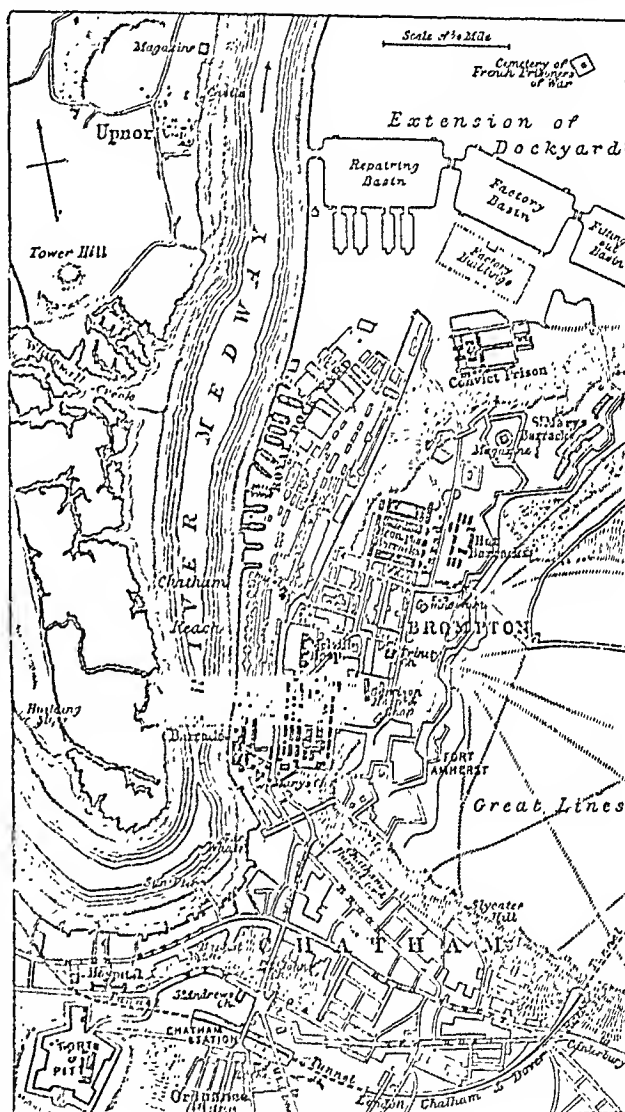

CHÂTEAU-THIERRY, a town of France, at the head of an arrondissement in the department of Aisne, on the right bank of the Marne, and connected with an extensive suburb on the opposite bank by a fine stone bridge of three arches. It is the seat of a tribunal of primary instance, and has a communal college, a public library, and manufactures of linen, cotton, leather, and earthenware. It contains a marble statue erected to the memory of La Fontaine, who was born in the town; and his house is still preserved in the street that was formerly called after the Cordeliers, but now bears the name of the poet. On the top of the hill are the ruins of a castle, which is said to have been built by Charles Martel for Thierry IV., and is plainly the origin of the name of the town. Château-Thierry was formerly the capital of the district of Brie Pouillense, and received the title of a duchy from Charles IX. in 1566. Its position has brought upon it numerous disasters from time to time. It was captured by the English in 1421, by Charles V. in 1515, and by the Spanish in 1591. During the wars of the Fronde it was pillaged in 1652; and in the campaign of 1814 it suffered severely. On February 12 of the latter year the Russo-Prussian forces were beaten by Napoleon in the neighbourhood. Population of the town in 1872, 5347; of the commune, 6623.

CHÂTELLERAULT, a town of France, at the head of an arrondissement in the department of Vienne, on the right bank of the Vienne, here crossed by a handsome stone bridge, which connects it with the suburb of Châteauneuf on the opposite side of the river, 24 miles N.N.E. of Poitiers. It stands in a fertile valley, and has several fine promenades, but is irregularly built. It has tribunals of primary instance and commerce, a fine Gothic church, a public fountain, a communal college, an exchange, a hospital, a society of agriculture, and a theatre. It is one of the chief seats of the manufacture of cutlery in France; and has a Government manufactory of swords and bayonets, established in 1820. There is a large trade in wines, dried fruits, slates, iron, corn, hemp, and timber. Population in 1872, 13,363.

Châtelleraunt, or *Castrum Heraldi*, derives its name from a castle built in the 11th century. In 1514 it was made a duchy in favour of Gilbert of Bourbon, count of Montpensier, but not long after it was reunited to the Crown. In 1518 it was bestowed on James Hamilton, second earl of Arran; but it was forfeited by failure of male issue. The title, however, continued to be claimed by the dukes of Hamilton and the earls of Abercorn, who were both descended by the female side from the original possessor. A decree of the French Council of State decided against the earl, and the title was bestowed on the duke of Hamilton by Napoleon III.

CHATHAM, a town of England, in the county of Kent, on the south side of the Medway about 15 miles from its junction with the estuary of the Thames, and 27 miles east of London. Though still nominally distinct, it is practically united with Rochester on the west, and is in close proximity to Brompton and Gillingham on the east. In Chatham proper the streets are for the most part narrow, and with the exception of the docks and fortifications, there are but few objects of interest. St Mary's church is a brick building erected about 1788, but occupying the site of an earlier structure of the 14th century; it contains a monumental brass to the memory of Stephen Borough, the discoverer of the northern passage to Russia. There are a few remains of the hospital for lepers founded by Bishop Gundulf in 1078; but the funds for its maintenance were appropriated by decision of the court of chancery to the new hospital of St Bartholomew erected in 1863 within the boundaries of Rochester. The almshouse, established in 1592 by Sir John Hawkins for poor decayed seamen and shipwrights, is still in existence, the building

having been re-erected in the present century; but the fund called the Chatham Chest, originated by Hawkins and Drake in 1588, was incorporated with Greenwich Hospital in 1802. The town possesses numerous churches and chapels of various denominations, a ragged school, a nautical school, a mechanics' institute, and a lecture hall. The Medway union workhouse is situated a short distance to the south-east. The water supply is obtained from springs at the village of Lupton, about half a mile further off in the same direction; and extensive reservoirs were constructed in 1862 at Star Hill in the neighbourhood of the village. Numerous brickyards, lime-kilns, and flour-mills are in the surrounding district, and the town carries on a large retail trade, partly from the presence of the garrison.

Plan of Chatham.

The fortifications are among the most elaborate in the kingdom. The so-called Chatham Lines ought rather to bear the name of the village of Brompton which they enclose. They were commenced in 1758 and completed in 1807; but various alterations and additions have since been effected. They are strengthened by several detached forts and redoubts, and consist of a very intricate system of trenches, batteries, and subterranean passages. Fort Pitt, which rises above the town to the west, was built in 1779, and is now used as a general military hospital; it was regarded as the principal establishment of the kind in the country till the foundation of Netley in Hampshire

The lines include the Chatham, the Royal Marine, the Brompton, the Hut, and St Mary's barracks; the garrison hospital and Melville hospital; the arsenal with its large park of artillery; the gymnasium, established in 1864 for gymnastic exercise; the military school for the practical instruction of sappers and engineers, opened in 1812; a military institute for the men in garrison; the convict prison; and, finally, the extensive system of dockyards which has made the town so famous.

Numerous Roman remains, both architectural and domestic, have been discovered at Chatham and Brompton; but they appear to have belonged to the Roman city of Rochester. Till the reign of Elizabeth the place was a mere insignificant village; but before 1588 the queen established the first dockyard on the site of what is now called the Ordnance Wharf, and erected Castle Upnor on the opposite bank of the river for its defence. The situation was changed in the following reign, and under the Charleses extensive additions were made. The history of the town since the attack of the Dutch in 1667 has been mainly the history of the naval and military establishments. The parliamentary borough, which returns one member, includes the towns of Chatham and Brompton, and the villages of Gillingham, Chatham Hill, and New Brompton, and covers an area of 2707 acres. The population of the borough in 1871 numbered 45,792 persons, of whom 24,873 were males and 20,919 females.

CHATHAM, WILLIAM PITT, FIRST EARL OF (1708-1778), one of the greatest of English statesmen and parliamentary orators, was born at Westminster on the 15th November 1708. He was the younger son of Robert Pitt of Boconnock, in Cornwall, and grandson of Thomas Pitt, governor of Madras, who was known as Diamond Pitt, from the fact of his having sold a diamond of extraordinary size to the Regent Orleans for £135,000. It was mainly by this fortunate transaction that the governor was enabled to raise his family, which was one of old standing, to a position of wealth and political influence. The latter he acquired by means of the former in the direct open method, then so common, purchasing the burgage tenures of Old Sarum, which was thus destined to become famous as represented by William Pitt a hundred years before it became notorious as the typical "rotten borough" in the debates on the first reform bill.

Of the early life of William Pitt comparatively little is known. He was educated at Eton, and in January 1726 was entered as a gentleman commoner at Trinity College, Oxford. There is evidence that he was an extensively read, if not a minutely accurate classical scholar; and it is interesting to know that Demosthenes was his favourite author, and that he diligently cultivated the faculty of expression by the practice of translation and re-translation. An hereditary gout, from which he had suffered even during his school-days, compelled him to leave the university without taking his degree, in order to travel abroad. He spent some time in France and Italy; but the disease proved intractable, and he continued subject to attacks of growing intensity at frequent intervals till the close of his life. In 1727 his father had died, and on his return home it was necessary for him, as the younger son, to choose a profession. Having chosen the army, he obtained through the interest of his friends a cornet's commission in the dragoons. But his military career was destined to be short. His elder brother Thomas having been returned at the general election of 1734 both for Oakhampton and for Old Sarum, and having preferred to sit for the former, the family borough fell to the younger brother by the sort of natural right usually recognized in such cases. Accordingly, in January 1735, William Pitt entered Parliament as member for Old Sarum. Attaching himself at once to

the formidable band of discontented Whigs known as the Patriots, whom Walpole's love of exclusive power had forced into opposition, he became in a very short time one of its most prominent members. His maiden speech was delivered in April 1736, in the debate on the congratulatory address to the king on the marriage of the prince of Wales. The occasion was one of compliment, and there is nothing striking in the speech as reported; but it served to gain for him the attention of the house when he presented himself, as he soon afterwards did, in debates of a party character. So obnoxious did he become as a critic of the Government, that Walpole thought fit to punish him by procuring his dismissal from the army. Some years later he had occasion vigorously to denounce the system of cashiering officers for political differences, but with characteristic loftiness of spirit he disdained to make any reference to his own case. The loss of his commission was soon made up to him. The heir to the throne, as has usually been the case in the house of Hanover, if not in reigning families generally, was the patron of the opposition, and the ex-cornet became groom of the bed-chamber to the prince of Wales. In this new position his hostility to the Government did not, as may be supposed, in any degree relax. He had all the natural gifts an orator could desire,—a commanding presence, a graceful though somewhat theatrical bearing, an eye of piercing brightness, and a voice of the utmost flexibility. His style, if occasionally somewhat turgid, was elevated and passionate, and it always bore the impress of that intensity of conviction which is the most powerful instrument a speaker can have to sway the convictions of an audience. It was natural, therefore, that in the series of stormy debates, protracted through several years, that ended in the downfall of Walpole, his eloquence should have been one of the strongest of the forces that combined to bring about the final result. Specially effective, according to contemporary testimony, were his speeches against the Hanoverian subsidies, against the Spanish convention in 1739, and in favour of the motion in 1742 for an investigation into the last ten years of Walpole's administration. It must be borne in mind that the reports of these speeches which have come down to us were made from hearsay, or at best from recollection, and are necessarily therefore most imperfect. The best known specimen of Pitt's eloquence, his reply to the sneers of Horatio Walpole at his youth and declamatory manner, which has found a place in all handbooks of elocution published during the last hundred years, is evidently, in form at least, the work, not of Pitt, but of Dr Johnson, who furnished the report to the *Gentleman's Magazine*. Probably Pitt did say something of the kind attributed to him, though even this is by no means certain in view of Johnson's repentant admission that he had often invented not merely the form but the substance of entire debates.

In 1742 Walpole was at last forced to succumb to the long continued attacks of the opposition, and was succeeded as prime minister by the earl of Wilmington, though the real power in the new Government was divided between Carteret and the Pelhams. Pitt's conduct on the change of administration was open to grave censure. The relentless vindictiveness with which he insisted on the prosecution of Walpole, and supported the bill of indemnity to witnesses against the fallen minister, was in itself not magnanimous; but it appears positively unworthy when it is known that a short time before Pitt had offered, on certain conditions, to use all his influence in the other direction. Possibly he was embittered at the time by the fact that, owing to the strong personal dislike of the king, caused chiefly by the contemptuous tone in which he had spoken of Hanover, he did not by obtaining a place in the

new ministry reap the fruits of the victory to which he had so largely contributed. The so-called "broad-bottom" administration formed by the Pelhams in 1744, after the dismissal of Carteret, though it included several of those with whom he had been accustomed to act, did not at first include Pitt himself even in a subordinate office. Before the obstacle to his admission was overcome, he had received a remarkable accession to his private fortune. The eccentric duchess of Marlborough, dying in 1744, at the age of ninety, left him a legacy of £10,000 as an "acknowledgment of the noble defence he had made for the support of the laws of England and to prevent the ruin of his country." As her hatred was known to be at least as strong as her love, the legacy was probably as much a mark of her detestation of Walpole as of her admiration of Pitt. It may be mentioned here, though it does not come in chronological order, that Pitt was a second time the object of a form of acknowledgment of public virtue which few statesmen have had the fortune to receive even once. About twenty years after the Marlborough legacy, Sir William Pynsent, a Somersetshire baronet to whom he was personally quite unknown, left him his entire estate, worth about three thousand a year, in testimony of approval of his political career.

It was with no very good grace that the king at length consented to give Pitt a place in the Government, although the latter did all he could to ingratiate himself at court, by changing his tone on the questions on which he had made himself offensive. To force the matter, the Pelhams had to resign expressly on the question whether he should be admitted or not, and it was only after all other arrangements had proved impracticable, that they were re-instated with the obnoxious politician as vice-treasurer of Ireland. This was in February 1746. In June of the same year he was promoted to the more important and lucrative office of paymaster-general, which gave him a place in the Privy Council, though not in the Cabinet. Here he had an opportunity of displaying his public spirit and integrity in a way that deeply impressed both the king and the country. It had been the usual practice of previous paymasters to appropriate to themselves the interest of all money lying in their hands by way of advance, and also to accept a commission of one-half per cent. on all foreign subsidies. Although there was no strong public sentiment against the practice, Pitt altogether refused to profit by it. All advances were lodged by him in the Bank of England until required, and all subsidies were paid over without deduction, even though it was pressed upon him, so that he did not draw a shilling from his office beyond the salary legally attaching to it. Conduct like this, though obviously disinterested, did not go without immediate and ample reward, in the public confidence which it created, and which formed the mainspring of Pitt's power as a statesman.

The administration formed in 1746 lasted without material change till 1754. It would appear from his published correspondence that Pitt had a greater influence in shaping its policy than his comparatively subordinate position would in itself have entitled him to. His conduct in supporting measures, such as the Spanish treaty and the Continental subsidies, which he had violently denounced when in opposition, had been much criticized. One of his biographers, Mr Thackeray, takes the trouble to offer an elaborate defence of it; but the vindication is in part unnecessary, and in part unsatisfactory. Within certain limits, not indeed very well defined, inconsistency has never been counted a vice in an English statesman. The times change, and he is not blamed for changing with the times. Pitt in office, looking back on the commencement of his public life, might have used the plea "A good deal has happened since then," at least as justly as some others have done. Allowance must always be made for the restraints

and responsibilities of office. In Pitt's case, too, it is to be borne in mind that the opposition with which he had acted gradually dwindled away, and that it ceased to have any organized existence after the death of the prince of Wales in 1751. Then in regard to the important question with Spain as to the right of search, Pitt has disarmed criticism by acknowledging that the course he followed during Walpole's administration was indefensible. All due weight being given to these various considerations, it must be admitted, nevertheless, that Pitt did overstep the limits within which inconsistency is usually regarded as venial. His one great object was first to gain office, and then to make his tenure of office secure by conciliating the favour of the king. The entire revolution which much of his policy underwent in order to effect this object bears too close a resemblance to the sudden and inexplicable changes of front habitual to placemen of the Tadpole stamp to be altogether pleasant to contemplate in a politician of pure aims and lofty ambition. Humiliating is not too strong a term to apply to a letter in which he expresses his desire to "efface the past by every action of his life," in order that he may stand well with the king.

In 1754 Henry Pelham died, and was succeeded at the head of affairs by his brother, the duke of Newcastle. To Pitt the change brought no advancement, and he had thus an opportunity of testing the truth of the description of his chief given by Sir Robert Walpole, "His name is treason." But there was for a time no open breach. Pitt continued at his post; and at the general election which took place during the year he even accepted a nomination for the duke's pocket borough of Aldborough. He had sat for Seaford since 1747. When Parliament met, however, he was not long in showing the state of his feelings. Ignoring Sir Thomas Robinson, the political nobody to whom Newcastle had entrusted the management of the Commons, he made frequent and vehement attacks on Newcastle himself, though still continuing to serve under him. In this strange state matters continued for about a year. At length, just after the meeting of Parliament in November 1751, Pitt was dismissed from office, having on the debate on the address spoken at great length against a new system of Continental subsidies, proposed by the Government of which he was a member. Fox, who had just before been appointed Secretary of State, retained his place, and though the two men continued to be of the same party, and afterwards served again in the same Government, there was henceforward a rivalry between them, which makes the celebrated opposition of their illustrious sons seem like an inherited quarrel.

Another year had scarcely passed when Pitt was again in power. The inherent weakness of the Government, the vigour and eloquence of his opposition, and a series of military disasters abroad combined to rouse a public feeling of indignation which could not be withstood, and in December 1756 Pitt, who now sat for Oakhampton, became Secretary of State, and leader of the Commons under the premiership of the duke of Devonshire. He had made it a condition of his joining any administration that Newcastle should be excluded from it, thus showing a resentment which, though natural enough, proved fatal to the lengthened existence of his Government. With the king unfriendly, and Newcastle, whose corrupt influence was still dominant in the Commons, estranged, it was impossible to carry on a Government by the aid of public opinion alone, however emphatically that might have declared itself on his side. In April 1757, accordingly, he found himself again dismissed from office on account of his opposition to the king's favourite Continental policy. But the power that was sufficient to keep him in office was strong enough to make any arrangement that excluded him impracticable. The

public voice spoke in a way that was not to be mistaken. Probably no English minister ever received in so short a time so many proofs of the confidence and admiration of the public, the capital and all the chief towns voting him addresses and the freedom of their corporations. From the political deadlock that ensued relief could only be had by an arrangement between Newcastle and Pitt. After some weeks' negotiation, in the course of which the firmness and moderation of "the Great Commoner," as he had come to be called, contrasted favourably with the characteristic tortuosities of the crafty peer, matters were settled on such a basis that, while Newcastle was the nominal, Pitt was the virtual head of the Government. On his acceptance of office he was chosen member for Bath.

This celebrated administration was formed in June 1757, and continued in power till 1761. During the four years of its existence it has been usual to say that the biography of Pitt is the history of England, so thoroughly was he identified with the great events which make this period, in so far as the external relations of the country are concerned, one of the most glorious in her annals. A detailed account of these events belongs to history; all that is needed in a biography is to point out the extent to which Pitt's personal influence may really be traced in them. It is scarcely too much to say that, in the general opinion of his contemporaries, the whole glory of these years was due to his single genius; his alone was the mind that planned, and his the spirit that animated the brilliant achievements of the British arms in all the four quarters of the globe. Posterity, however, has taken the liberty of revising this enthusiastic verdict, and has placed his renown on what seems a truer and therefore a firmer basis. It has recognized more fully than his contemporaries the independent genius of those who, as subordinates or allies, carried out his purposes. The heroism of Wolfe would have been irrepressible, Clive would have proved himself "a heaven-born general," and Frederick the Great would have written his name in history as one of the most skilful strategists the world has known, whoever had held the seals of office in England. But Pitt's relation to all three was such as to entitle him to a large share in the credit of their deeds. It was his discernment that selected Wolfe to lead the attack on Quebec, and gave him the opportunity of dying a victor on the heights of Abraham. He had personally less to do with the successes in India than with the other great enterprises that shed an undying lustre on his administration; but his generous praise in Parliament stimulated the genius of Clive, and the forces that acted at the close of the struggle were animated by his indomitable spirit. Frederick the Great's Seven Years' War might well have been another Thirty Years' War, if Pitt had not furnished him with an annual subsidy of £700,000, and in addition relieved him of the task of defending Western Germany against France.

Contemporary opinion was, of course, incompetent to estimate the permanent results gained for the country by the brilliant foreign policy of Pitt. It has long been generally agreed that by several of his most costly expeditions nothing was won but empty glory. It has even been said that the only permanent acquisition that England owes directly to him is her Canadian dominion; and, strictly speaking, this is true, it being admitted that the campaign by which the Indian empire was virtually won was not planned by him, though brought to a successful issue during his ministry. But material aggrandizement, though the only tangible, is not the only real or lasting effect of a war policy. More may be gained by crushing a formidable rival than by conquering a province. The loss of her Canadian possessions was only one of a series of disasters suffered by France, which radically affected the

future of Europe and the world. Deprived of her most valuable colonies both in the East and in the West, and thoroughly defeated on the Continent, her humiliation was the beginning of a new epoch in history. The victorious policy of Pitt destroyed the military prestige which repeated experience has shown to be in France as in no other country the very life of monarchy, and thus was not the least considerable of the many influences that slowly brought about the French Revolution. It effectually deprived her of the lead in the councils of Europe which she had hitherto arrogated to herself, and so has affected the whole course of Continental politics to the present time. It is such far-reaching results as these, and not the mere acquisition of a single colony, however valuable, that constitute Pitt's claim to be considered as on the whole the most powerful minister that ever guided the foreign policy of England.

The first and most important of a series of changes which ultimately led to the dissolution of the ministry was the death of George II. on the 25th October 1760, and the accession of his grandson, George III. The new king had, as was natural, new counsellors of his own, the chief of whom, Lord Bute, was at once admitted to the cabinet as a secretary of state. Between Bute and Pitt there speedily arose an occasion of serious difference. The existence of the so-called family compact by which the Bourbons of France and Spain bound themselves in an offensive alliance against England having been brought to light, Pitt urged that it should be met by an immediate declaration of war with Spain. To this course Bute would not consent, and as his refusal was endorsed by all his colleagues save Temple, Pitt had no choice but to leave a cabinet in which his advice on a vital question had been rejected. On his resignation, which took place in October 1761, the king urged him to accept some signal mark of royal favour in the form most agreeable to himself. Accordingly he obtained a pension of £3000 a year for three lives, and his wife, Lady Hester Grenville, whom he had married in 1754, was created Baroness Chatham in her own right. In connection with the latter gracefully bestowed honour it may be mentioned that Pitt's domestic life was a singularly happy one.

Pitt's spirit was too lofty to admit of his entering on any merely factions opposition to the Government he had quitted. On the contrary, his conduct after his retirement was distinguished by a moderation and disinterestedness which, as Burke has remarked, "set a seal upon his character." The war with Spain, in which he had urged the Cabinet to take the initiative, proved inevitable; but he scorned to use the occasion for "altercation and recrimination," and spoke in support of the Government measures for carrying on the war. To the preliminaries of the peace concluded in February 1763 he offered an indignant resistance, considering the terms quite inadequate to the successes that had been gained by the country. When the treaty was discussed in Parliament in December of the preceding year, though suffering from a severe attack of gout, he was carried down to the house, and in a speech of three hours' duration, interrupted more than once by paroxysms of pain, he strongly protested against its various conditions. The physical cause which rendered this effort so painful probably accounts for the infrequency of his appearances in Parliament, as well as for much that is otherwise inexplicable in his subsequent conduct. In 1763 he spoke against the obnoxious tax on cider, imposed by his brother-in-law, George Grenville, and his opposition, though unsuccessful in the house, helped to keep alive his popularity with the country, which cordially hated the excise and all connected with it. When next year the question of general warrants was raised in connection with the case of

Wilkes, Pitt vigorously maintained their illegality, thus defending at once the privileges of Parliament and the freedom of the press. During 1765 he seems to have been totally incapacitated for public business. In the following year he supported with great power the proposal of the Rockingham administration for the repeal of the American Stamp Act, arguing that it was unconstitutional to impose taxes upon the colonies. He thus endorsed the contention of the colonists on the ground of principle, while the majority of those who acted with him contented themselves with resisting the disastrous taxation scheme on the ground of expediency. The Repeal Act, indeed, was only passed *pari passu* with another censuring the American Assembly, and declaring the authority of the British Parliament over the colonies "in all cases whatever;" so that the House of Commons repudiated in the most formal manner the principle Pitt laid down. His language in approval of the resistance of the colonists was unusually bold, and perhaps no one but himself could have employed it with impunity at a time when the freedom of debate was only imperfectly conceded.

Pitt had not been long out of office when he was solicited to return to it, and the solicitations were more than once renewed. Unsuccessful overtures were made to him in 1763, and twice in 1765, in May and June,—the negotiator in May being the king's uncle, the duke of Cumberland, who went down in person to Hayes, Pitt's seat in Kent. It is known that he had the opportunity of joining the marquis of Rockingham's short-lived administration at any time on his own terms, and his conduct in declining an arrangement with that minister has been more generally condemned than any other step in his public life. Even Thackeray, his admiring biographer, has admitted that in this matter he was "neither kind as a man nor wise as a politician." In the autumn of 1766 Rockingham was dismissed, and Pitt was entrusted by the king with the task of forming a Government entirely on his own conditions. The result was a cabinet, strong much beyond the average in its individual members, but weak to powerlessness in the diversity of its composition. Burke, in a memorable passage of a memorable speech, has described this "chequered and speckled" administration with great humour, speaking of it as "indeed a very curious show, but utterly unsafe to touch and unsure to stand on." Pitt chose for himself the office of Lord Privy Seal, which necessitated his removal to the House of Lords; and he became Viscount Pitt and Earl of Chatham.

By the acceptance of a peerage the great commoner lost at least as much and as suddenly in popularity as he gained in dignity. One significant indication of this may be mentioned. In view of his probable accession to power, preparations were made in the city of London for a banquet and a general illumination to celebrate the event. But the celebration was at once countermanded when it was known that he had become earl of Chatham. The instantaneous revulsion of public feeling was somewhat unreasonable, for Pitt's health seems now to have been beyond doubt so shattered by his hereditary malady, that he was already in old age though only fifty-eight. It was natural, therefore, that he should choose a sinecure office and the ease of the Lords. But a popular idol nearly always suffers by removal from immediate contact with the popular sympathy, be the motives for removal what they may.

One of the earliest acts of the new ministry was to lay an embargo upon corn, which was thought necessary in order to prevent a dearth resulting from the unprecedentedly bad harvest of 1766. The measure was strongly opposed, and Lord Chatham delivered his first speech in the House of Lords in support of it. It proved to be almost the only measure introduced by his Government in which he personally interested himself. His attention

had been directed to the growing importance of the affairs of India, and there is evidence in his correspondence that he was meditating a comprehensive scheme for transferring much of the power of the company to the Crown, when he was withdrawn from public business in a manner that has always been regarded as somewhat mysterious. It may be questioned, indeed, whether even had his powers been unimpaired he could have carried out any decided policy on any question with a cabinet representing interests so various and conflicting; but, as it happened, he was incapacitated physically and mentally during nearly the whole period of his tenure of office. He scarcely ever saw any of his colleagues though they repeatedly and urgently pressed for interviews with him, and even an offer from the king to visit him in person was declined, though in the language of profound and almost abject respect which always marked his communications with the court. It has been insinuated both by contemporary and by later critics that being disappointed at his loss of popularity, and convinced of the impossibility of co-operating with his colleagues, he exaggerated his malady as a pretext for the inaction that was forced upon him by circumstances. But there is no sufficient reason to doubt that he was really, as his friends represented, in a state that utterly unfitted him for business. He seems to have been freed for a time from the pangs of gout only to be afflicted with a species of mental alienation bordering on insanity. This is the most satisfactory, as it is the most obvious, explanation of his utter indifference in presence of one of the most momentous problems that ever pressed for solution on an English statesman. Those who are able to read the history in the light of what occurred later may perhaps be convinced that no policy whatever initiated after 1766 could have prevented or even materially delayed the declaration of American independence; but to the politicians of that time the coming event had not yet cast so dark a shadow before as to paralyze all action, and if any man could have allayed the growing discontent of the colonists and prevented the ultimate dismemberment of the empire, it would have been Lord Chatham. The fact that he not only did nothing to remove existing difficulties, but remained passive while his colleagues took the fatal step which led directly to separation, is in itself clear proof of his entire incapacity. The imposition of the import duty on tea and other commodities was the project of Charles Townshend, and was carried into effect in 1767 without consultation with Lord Chatham, if not in opposition to his wishes. It is probably the most singular thing in connection with this singular administration, that its most pregnant measure should thus have been one directly opposed to the well-known principles of its head.

For many months things remained in the curious position that he who was understood to be the head of the cabinet had as little share in the government of the country as an enfranchised peasant. As the chief could not or would not lead, the subordinates naturally chose their own paths and not his. The lines of Chatham's policy were abandoned in other cases besides the imposition of the import duty; his opponents were taken into confidence; and friends, such as Amherst and Shelburne, were dismissed from their posts. When at length in October 1768 he tendered his resignation on the ground of shattered health, he did not fail to mention the dismissal of Amherst and Shelburne as a personal grievance.

Soon after his resignation a renewed attack of gout freed Chatham from the mental disease under which he had so long suffered. He had been nearly two years and a half in seclusion when, in July 1769, he again appeared in public at a royal levee. It was not, however, until 1770 that he resumed his seat in the House of Lords. He had

now almost no personal following; mainly owing to the grave mistake he had made in not forming an alliance with the Rockingham party. But his eloquence was as powerful as ever, and all its power was directed against the Government policy in the contest with America, which had become the question of all absorbing interest. His last appearance in the House of Lords was on the 2d April 1778, on the occasion of the duke of Richmond's motion for an address praying the king to conclude peace with America on any terms. In view of the hostile demonstrations of France the various parties had come generally to see the necessity of such a measure. But Chatham could not brook the thought of a step which implied submission to the "natural enemy" whom it had been the main object of his life to humble, and he declaimed for a considerable time, though with sadly diminished vigour, against the motion. After the duke of Richmond had replied, he rose again excitedly as if to speak, pressed his hand upon his breast, and fell down in a fit. He was removed to his seat at Hayes, where he died on the 11th May. With graceful unanimity all parties combined to show their sense of the national loss. The Commons presented an address to the king praying that the deceased statesman might be buried with the honours of a public funeral, and voted a sum for a public monument which was erected over his grave in Westminster Abbey. Soon after the funeral a bill was passed bestowing a pension of £4000 a year on his successors in the earldom. He had a family of three sons and two daughters, of whom the second son, William, was destined to add fresh lustre to a name which is one of the greatest in the history of England.

Dr Johnson is reported to have said that "Walpole was a minister given by the king to the people, but Pitt was a minister given by the people to the king," and the remark correctly indicates Chatham's distinctive place among English statesmen. He was the first minister whose main strength lay in the support of the nation at large as distinct from its representatives in the Commons, where his personal following was always small. He was the first to discern that public opinion, though generally slow to form and slow to act, is in the end the paramount power in the state; and he was the first to use it not in an emergency merely, but throughout a whole political career. He marks the commencement of that vast change in the movement of English politics by which it has come about that the sentiment of the great mass of the people now tells effectively on the action of the Government from day to day,—almost from hour to hour. He was well fitted to secure the sympathy and admiration of his countrymen, for his virtues and his failings were alike English. He was often inconsistent, he was generally intractable and overbearing, and he was always pompous and affected to a degree which, Macaulay has remarked, seems scarcely compatible with true greatness. Of the last quality evidence is furnished in the stilted style of his letters, and in the fact recorded by Seward that he never permitted his under-secretaries to sit in his presence. Burke speaks of "some significant, pompous, creeping, explanatory, ambiguous matter, in the true Chathamian style." But these defects were known only to the inner circle of his associates. To the outside public he was endeared as a statesman who could do or suffer "nothing base," and who had the rare power of transfusing his own indomitable energy and courage into all who served under him. "A spirited foreign policy" has always been popular in England, and Pitt was the most popular of English ministers, because he was the most successful exponent of such a policy. In domestic affairs his influence was small and almost entirely indirect. He himself confessed his unfitness for dealing with questions of finance. The commercial prosperity that was produced

by his war policy was in a great part decisive, as prosperity so produced must always be, though it had permanent effects of the highest moment in the rise of such centres of industry as Glasgow. This, however, was a remote result which he could have neither intended nor foreseen. More directly attributable to him was the policy which led to the pacification of the Highlands of Scotland. With the happy instinct of a chivalrous mind he advised the formation of the Highland regiments, and so succeeded in transforming high-spirited though mistaken rebels into the bravest and most loyal soldiers of the British crown.

See *A History of the Right Hon. William Pitt, Earl of Chatham*, (2 vols. 4to, 1827) by the Rev. Francis Thackeray; *Correspondence of William Pitt, Earl of Chatham* (4 vols. 8vo. 1838-40); and *Almon's Anecdotes of Chatham, with his Speeches in Parliament* (2 vols. 4to, 1792). A volume of Pitt's letters to his nephew, Thomas Pitt, Lord Camelford, was published in 1804. (W. B. S.)

CHATHAM ISLANDS, a group in the Pacific, 560 miles east of New Zealand, lying between 43° 40' and 45° 20' S. lat., and between 176° 10' and 177° 20' W. long. It consists of three islands, a large one called Wari-Kauri, or Chatham Island, a smaller one, Rangi-Haute, or Pitt's Island, and a third, Rangatira, or South-east Island. There are also several small rocky islets. Chatham Island, according to Dicffenbach, contains an area of 305,280 acres; of which, however, 57,600 acres are lakes and lagoons. In the centre is a large brackish lake called Tewanga, about 25 miles long and 6 or 7 broad, which at the southern end is separated from the sea by a sandbank only 150 yards wide, which it occasionally bursts through. The southern part of the island has an undulating surface, and is covered either with an open forest or with high ferns. In general the soil is extremely fertile, and where it is naturally drained, a rich vegetation of fern and flax (*Phormium tenax*) has sprung up, giving firmness to the soil and yielding a rich harvest to the planter. On the north-west are three or four conical hills of basalt, which are surrounded by oases of fertile soil. On the western side is Petre Bay, 40 miles across, on which, at the mouth of the River Mangatu, is Waitangi, the principal settlement. The country to the east of the great lagoon is quite flat, and is scarcely 50 feet above the sea-level. The climate is very mild, in winter varying only from 45° to 60°. The changes of temperature are less sudden than in New Zealand. The inhabitants cultivate potatoes, turnips, cabbages, taro (esculent arum), tobacco, and pumpkins. The trees and shrubs resemble those of New Zealand, but the former are of very small size. Horses and cattle are bred in considerable numbers for the New Zealand market. Birds of many kinds, chiefly ducks, snipes, plovers, curlews, redbills, sandlarks, and parrots, abound. Fish are plentiful on the coast, and whaling is actively prosecuted all round the group. Pitt's Island is about 12 miles long and 8 broad; it has no harbour. These islands were discovered in 1791 by Lieutenant Broughton, who gave them the name of Chatham from the brig which he commanded. The natives, who are known as Morioris or Maiorioris, were conquered in 1832-33 by the Maoris of New Zealand, who killed great numbers of them, and in 1839 half of those left died of an epidemic of influenza. Their numbers have been reduced from 1500 to 140, and they are now a feeble and degenerate race. The geology and the flora and fauna of the islands indicate their physical connection with New Zealand, to which politically they belong.

CHÂTILLON-SUR-SEINE, a town of France, formerly the capital of the Pays de la Montagne or Country of the Mountain, in Burgundy, and now at the head of an arrondissement in the department of Côte d'Or, is situated about 40 miles south-west of Troyes on the Upper Seine. It is built on both sides of the river, and formerly consisted

of two distinct portions known as Chaumont and Bourg, each with its own fortifications. It is the seat of a court of primary instance, and possesses the ruins of a magnificent castle, a hospital, a town-house, a communal college, a public library, and some fine promenades. The church of St Vorle dates from the 12th century, and contains a number of frescoes included among the historic monuments of France. Marshal Marmont, duke of Ragusa, who was born in the town in 1774, has left a memento in the shape of a handsome chateau. A considerable trade is maintained by Châtillon in timber, wool, leather, and lithographic stones; and it has cloth-factories, paper-mills, foundries, flour-mills, and various other industrial establishments. The origin of the town probably dates from the 5th century. For several centuries it was a favourite residence of the dukes of Burgundy. In modern times it is mainly remarkable for the conference held, in February 1814, between Napoleon and the Allies, in which the former rejected the proposal that he should rule over the France of pre-Revolutionary limits. Population in 1872, 4691.

CHATSWORTH, the seat of the duke of Devonshire, one of the most splendid private residences in England, is situated in Derbyshire, on the River Derwent, $3\frac{1}{2}$ miles north-east of the village of Bakewell, and 8 miles west of the town of Chesterfield. It stands on the left bank of the river, opposite the hamlet of Edensor, and as seen from the west presents a magnificent façade in fine relief against the wooded ridge of Lunker's Hill. The building is in the Ionic style, and the principal part is composed of four nearly equal sides, surrounding an open quadrangular court with a fountain in the centre. A wing and other somewhat extensive additions have been made since 1820. Chatsworth contains some beautiful wood carvings by Gibbons and Watson, several pieces of sculpture by Canova, Thorwaldsen, Chantrey, and Wyatt, and a unique collection of original drawings by Titian, Rubens, Salvator Rosa, Raphael, Claude Lorraine, and others of the older masters. The park is upwards of 11 miles in circuit; the gardens are among the most celebrated in the kingdom, and cover an area of twelve acres. The grand conservatory, an acre in extent, erected by Sir Joseph Paxton, is unequalled by any in Europe; and the waterworks, which include one fountain with a jet 260 feet high, are only surpassed by those of Versailles. The domain of Chatsworth is mentioned in *Domesday Book* as Chetesworde. In the 16th century it was purchased by Sir William Cavendish. The mansion which he erected afterwards served as a place of confinement for Mary Queen of Scots from 1570 to 1581. It has entirely disappeared; and the present building was commenced in 1688 by the first duke of Devonshire and was completed in 1840 by the seventh.

CHATTANOOGA, a city of the United States, in the county of Hamilton, Tennessee, about 250 miles by water from Knoxville, at the foot of Lookout Mountain, on the left bank of the Tennessee river, which is navigable for steamers during eight months of the year. It has free communication by four railway lines, and carries on a pretty extensive trade in the produce of the surrounding district, which is well supplied with timber, iron-ore, and coal. Among its industrial establishments are saw-mills and wood-work factories. In 1862 and 1863 the Confederates were defeated here by the Federal forces under General Grant. Population in 1870, 6093, of whom 2221 were coloured.

CHATTERTON, THOMAS (1752-1770). Among the poets of the 18th century, Thomas Chatterton occupies a place altogether unique. He indeed claims scarcely less the interest of the psychologist as a marvellous example of matured intellectual precocity, than that of the student of English literature as a poet remarkable in an age of varied literary excellence. Fully to estimate the characteristics

in which Chatterton stands out with such exceptional prominence, it has to be kept constantly in view that he was a posthumous child, the son of a poor widow, self-taught in all but the merest rudiments of education acquired at a charity school; that, so far from receiving encouragement, he was thwarted at every step in his strange, brief career; and that he was buried by strangers, in a pauper's grave, when only seventeen years of age.

Born though Chatterton was in a humble rank of life, his pedigree has a curious significance. The office of sexton of St Mary Redcliffe, at Bristol, one of the most beautiful specimens of parochial church architecture in England, had been transmitted for nearly two centuries in the Chatterton family; and throughout the brief life of the poet it was held by his uncle, Richard Phillips. The poet's father—the first of the Chattertons who aspired to a position requiring education and natural ability—was a musical genius, somewhat of a poet, an antiquary, and a dabbler in occult arts. He was one of the subchanters of Bristol Cathedral, and master of the Pyle Street Free School in the vicinity of Redcliffe church. But whatever hereditary tendencies may have been transmitted from the father, the solo training of the boy necessarily devolved on his mother, who was in the fourth month of her widowhood at the time of his birth (20th November 1752).

The young widow established a girl's school, took in sewing and ornamental needlework, and so brought up her two children, a girl and boy, till the latter attained his eighth year, when he was admitted to Colston's Charity. But the Bristol blue-coat school had little share in the education of its marvellous pupil. The hereditary race of sextons had come to regard the church of St Mary Redcliffe as their own peculiar domain; and, under the guidance of his uncle, the orphan child found there his favourite haunt. The knights, ecclesiastics, and civic dignitaries, recumbent on its altar tombs, became his familiar associates; and by and by, when he was able to spell his way through the inscriptions graven on their monuments, he found a fresh interest in certain quaint oaken chests in the muniment room over the porch on the north side of the nave, where parchment deeds, old as the Wars of the Roses, long lay unheeded and forgotten. His father, the schoolmaster, had already made free with them for wrappers to his copy books; his mother turned them to account for thread papers and patterns; and they formed the child's playthings almost from his cradle. He learned his first letters from the illuminated capitals of an old musical folio, and turned to account deeds and charters of the Henrys and Edwards as his primers. Wayward, as it seems, almost from his earliest years, and manifesting no sympathy with the ordinary pastimes of children, he was regarded for a time as deficient in intellect. But he was even then ambitious of distinction. One of his sister's earliest recollections of him was his thirst for pre-eminence. He was confident in his own resources, and while still little more than a child was wont to say that a man might do anything he chose. But from his earliest years he was liable to fits of abstraction, sitting for hours in seeming stupor, or yielding after a time to tears, for which he would assign no reason. He had no one near him to sympathize in the strange world of fancy which his imagination had already called into being, or to feel any interest in the wonderful productions of his pen, which ere long were the fruits of such musings.

The influence of this lack of appreciative sympathy, along with the suspicions which his incomprehensible love of solitude excited, helped to foster his natural reserve, and beget that love of mystery which exercised so great an influence on the development of his genius. When the strange child had attained his sixth year his mother began to recognize his capacity; at eight he was so eager for

books that when unrestrained he would read from an early hour till bed-time; and by the time he reached his eleventh year he had become a contributor to *Felix Farley's Bristol Journal*. A beautiful cross of curious workmanship had adorned the churchyard of St Mary Redcliffe for upwards of three centuries, until, in 1763, it became an object of offence to an over zealous churchwarden, and was swept away. The spirit of veneration was strong in the boy; and taking up his pen, he sent to the local journal a clever satire on the parish Vandal. Other juvenile productions followed, characteristic of the precocity of their author; and under various disguises he sported with the satiric muse, or in graver mood strove to awake some reverence for the past in the unsympathetic community amid which his lot was cast. He had a bold independent bearing; and except during his fits of reverie, he was frank and companionable, and manifested a special fondness for female society. But his delight was to lock himself in a little attic which he had appropriated as his study, and there, with books, parchments, and drawing materials, the child already dalled with the muse, and began the strange literary maskings on which his fame depends.

On the 3d of August 1760, when in his eighth year, Chatterton was admitted to all the privileges of Colston's Hospital. This charity is popularly styled the Blue-coat School of Bristol, and as such has been referred to as an institution of a similar character to that of Christ's Hospital, London. But except in the quaint, half-monkish garb of its inmates, Colston's Hospital bore little resemblance to the foundation where Barnes and Markland acquired their scholarship, and Lamb and Coleridge found culture for their genius. The "great house on St Augustine's Back," which had been converted to the use of Colston's Charity, was a fine civic mansion erected in Tudor times on the site of a dissolved house of Friars Carmelites. Queen Elizabeth had held court there in 1581; and when the Stuarts succeeded to the Tudors, its hospitalities had been exercised by Sire Ferdinand Gorges, one of the merchant princes of the old seaport. But though Edward Colston, as the representative of a line of merchant adventurers who had flourished in Bristol in the reign of Edward III., no less deserved that title, the civic mansion when transferred to his care rather resembled the dwelling of the older friars, except in its lack of their redeeming feature of monkish learning. Bristol had its grammar school, with liberal endowments and university exhibitions, for the sons of its more favoured citizens. But the rules of Colston's Hospital provided for the training of its inmates in "the principles of the Christian religion, as laid down in the church catechism," and in fitting them to be apprenticed in due course to some trade. But Chatterton was too young, as yet, to comprehend the difference between the two schools. He was thirsting for knowledge, and was greatly elated at his election on the foundation, "thinking," as his foster-mother said, "that he should there get all the learning he wanted." But he speedily discovered that its meagre curriculum was inadequate to his cravings, and he indignantly complained that he could not learn so much as at home.

Chatterton remained an inmate of Colston's Hospital for upwards of six years, learning little more than the most ordinary elements of a common school education; and its chief value was that it lightened to his poor mother the burden of his maintenance. Some influences, however, of a more congenial character are traceable to the friendly sympathy of one of its ushers. Thomas Phillips, himself a writer of verse, strove to excite a spirit of emulation among the older of his pupils and found in Chatterton a response to his appeal. Three of his companions are named along with him, as youths whom Phillips's taste for poetry stimulated to rivalry, and are long eulisted among the

contributors to *Felix Farley's Journal*. But Chatterton had already conceived more daring literary adventures; and it was while still an inmate of Colston's Charity that he essayed on Phillips his first serious attempt to pass off verses of his own as the production of a poet of the 15th century. Except, indeed, in the immaturity and inexperience inseparable from his years, Chatterton was the superior of those to whose society he was limited, and was in all essential respects his own teacher. His little pocket-money was spent in borrowing books from a circulating library; and he early ingratiated himself with book collectors, by whose aid he found access to Weever, Dugdale, and Collins, as well as to Chaucer, Spenser, and other writers strangely out of the line of reading of a charity boy, or indeed of any boy of his age. His holidays were mostly spent at his mother's house; and much of them in the favourite retreat of his attic study there. He had already conceived the romance of an imaginary monk of the 15th century, and lived for the most part in an ideal world of his own, relegated to that elder time when Edward IV. was England's king, and Master William Canynge—familiar to him among the recumbent effigies in Redcliffe church—still ruled in Bristol's civic chair. "The Storie of William Canynge," a poem of great beauty which constitutes one of the shorter pieces of his ingenious romance, represents the bard endowed by Truth, a heavenly maid, with divine insight, and so translated to those elder times, and that more real poetic life, in which Chatterton had revelled from his own childhood:—

"Straight was I carried back to times of yore,
Whilst Canynge swathed yet in fleshly bed,
And saw all actions which had been before,
And all the scroll of Fate unravelled;
And when the fate-marked babe awoke to sight,
I saw him eager gasping after light.
In all his simple gambols and child's play,
In every merry-making, fair, or wake,
I kenn'd a perpled light of wisdom's ray;
He ate down learning with the wastel-cake;
As wise as any of the aldermen,
He'd wit enow to make a mayor at ten."

This beautiful picture of the childhood of the ideal patron of Rowley is in reality that of the poet himself,— "the fate-marked babe," with his wondrous child-genius, and all his romantic dreams realized. The first lines are, indeed, referred to by Mr Skent, in his annotated edition of the poems, as "clearly an oversight," in which the poet writes in his own person and modern character, and so introduces "an unconscious admission of forgery." The literary masquerade which thus constituted the life-dream of the boy was wrought out by him with marvellous consistency into a coherent romance, until the credulous scholars and antiquaries of his day were persuaded into the belief that there had lain in the parish chest of Redcliffe church for upwards of three centuries, a collection of poems of rare merit, the work of Thomas Rowley, an unknown priest of Bristol in the days of Henry VI. and his poet laureate, John Lydgate.

Among the Bristol patrons of Chatterton, Mr George Catcott and Henry Burgum, his partner in their trade as pewterers, occupy a prominent place. The former was one of the most zealous accreditors of Rowley, the imaginary priest and poet of the times of the Roses, and continued to collect his reputed writings long after the death of their real author. The credulity of the other was subjected to a more severe test. He had come from Gloucestershire to Bristol, a poor friendless boy, and himself owed to one of Colston's charities his first start in life. He had risen, mainly by his own exertions, to the position of a successful tradesman, and gave full licence to the vanity with which he asserted the claims of his new position. On him, accordingly, the blue-coat boy palmed off the De

Bergham pedigree, and other equally apocryphal evidences of the pewterer's descent from an ancestry old as the Norman Conquest. The De Bergham quarterings, blazoned on a piece of parchment doubtless recovered from the Redcliffe muniment chest, was itself supposed to have lain for centuries in that ancient depository. The pedigree was professedly collected by Chatterton from original records, including "The Rowley MSS." Into this he introduced an ingenious romance of one of the pewterer's ancestors, who was also a metallurgist, though after a more dignified fashion. According to this the De Bergham of that elder time obtained from Henry VI. a royal patent to play the alchemist, and so to transmute pewter and other base metals into gold. He left issue four sons, one of whom figures as "Edward Asheton of Chatterton, in Com. Lane. in the right of his wife, the daughter and heiress of Radcliffe de Chatterton of Chatterton, the heir general of many families." The pedigree still exists in Chatterton's own handwriting, copied into a book in which he had previously transcribed portions of antique verse, under the title of "Poems by Thomas Rowley, priest of St John's, in the city of Bristol;" and in one of these, "The Tournament," Syrr Johan de Berghamme plays a conspicuous part. The ennobled pewterer rewarded Chatterton with five shillings, and was satirized for this valuation of a noble pedigree in some of his latest verse. The pedigree and all its accessories are crude enough; but as the production of a boy not fourteen years of age, whose whole education had been acquired in a charity school, it is a remarkable evidence of precocity.

On the 1st of July 1767, before he had completed the seventh year of his residence in Colston's Hospital, Chatterton was transferred to the office of Mr John Lambert, attorney, to whom he was bound apprentice as a clerk. There he was left much alone; and after fulfilling the routine duties devolving on him, he found leisure for his own favourite pursuits. An ancient stone bridge on the Avon, built in the reign of Henry II., and altered by many later additions into a singularly picturesque but inconvenient thoroughfare, had been displaced by a structure better adapted to modern requirements. In the month of September 1768, when Chatterton was in the second year of his apprenticeship, the new bridge was partially opened for traffic. Shortly afterwards the editor of *Felix Farley's Journal* received from a correspondent, signing himself *Dunelmus Bristolensis*, a "description of the mayor's first passing over the old bridge," professedly derived from an ancient MS. Mr William Barrett, F.S.A., surgeon and antiquary, who was then accumulating materials for a history of Bristol, secured the original manuscript, which is now preserved in the British Museum, along with other Chatterton MSS., most of which were ultimately incorporated by the credulous antiquary into a learned quarto volume, entitled the *History and Antiquities of the City of Bristol*, published nearly twenty years after the poet's death.

The publication of the description of the ancient opening of the bridge naturally excited inquiry; for the picturesque narrative acquired a suitable flavour of antiquity, without being too much obscured for the general reader, by its archaic language and spelling; and so a desire was manifested to trace it to its source. Chatterton was ere long recognized as its contributor, on presenting himself at the office of the *Bristol Journal* with another of his productions; and then it was that the definite story made its appearance—over which critics and antiquaries wrangled for nearly a century—of numerous ancient poems and other MSS. taken by the elder Chatterton from a coffer in the muniment room of Redcliffe church, and transcribed, and so rescued from oblivion, by his son.

The dream of the boy-poet was of an age devoid of all the sordid meanness of his own, and of a patron of the muses generous as the ideal Canynge of his romance. Living in this imaginary world, he continued to invent, and ascribe to the authorship of the good priest Thomas Rowley, dramatic, lyrical, and descriptive poems, along with letters, fragments of local or general history, and other miscellaneous productions in prose,—nearly all of them pertaining to the romance of Rowley and Master Canynge, the old citizen and mayor of Bristol. With a persistent coherence to this ideal, which he had formed in his own mind while still a mere child, Chatterton produced nearly all the marvellous literary creations on which his fame depends. In the interval between his first-known antique ballad, the "Elmour and Juga," written while still an inmate of Colston's Hospital, and his leaving Bristol at the age of seventeen, his pieces include the "Bristowe Tragedy," another and longer ballad; his "Ella, a Tragical Interlude," as he styles it, but in reality a dramatic poem of sustained power and curious originality of structure; his "Goddwyn," another dramatic poem; his "Tournament," "Battle of Hastings," "The Parliament of Sprites," with numerous smaller pieces of antique verse—forming altogether a goodly volume of poetry, the rare merit of which is indisputable, wholly apart from the fact that it was the production of a mere boy.

Yet this only partially illustrates the fertility of his genius. During the same period he had thrown off numerous lyrics, and had given vent to his satirical humour in several lengthened poems, which, though for the most part inferior in merit to his antique verse, would excite wonder as the sole productions of any boy of his age. But the authorship even of those modern poems was rarely avowed. The habit of secretiveness grew ere long into a love of mystery, which ultimately proved prejudicial to the boy. Unfortunately for him, his ingenious romance had either to be acknowledged as his own creation, and so in all probability be treated with contempt, or it had to be sustained by the manufacture of spurious antiques. To this accordingly Chatterton resorted, and found no difficulty in gulling the most learned of his credulous dupes with his parchments.

The literary labours of the boy, though diligently pursued at his desk, were not allowed to interfere with the duties of Mr Lambert's office. Nevertheless such a mode of employing any portion of his time was peculiarly distasteful to the Bristol attorney. He was wont to search his apprentice's drawer, and to tear up any poems or other manuscripts that he could lay his hands upon; so that it was only during the absences of Mr Lambert from Bristol that he was able to expend his unemployed time in his favourite pursuits. But repeated allusions, both by Chatterton and others, seem to indicate that such intervals of freedom were of frequent occurrence. Then he could finish his average two hours of legitimate office work, attend to whatever other duties devolved upon him, and thereafter betake himself to song or satire, or abandon himself to the romance of that antique world in which his pleasantest hours were passed.

But such intervals of freedom only tended to increase his dislike for the restraints of office-life under his master's eye. In every changing mood of mind he was prone to seek relief in his pen;—yielding at times to earnest thought, and giving lyrical form to his religious feelings and convictions; at other times giving freest scope to his satirical humour, and subjecting all who came within its range to ridicule or scornful invective; or again, lapsing into romantic reverie, and revelling in the creations of his antique muse. Some of his modern poems, such as the piece entitled "Resignation," are of great beauty; and these, with the satires, in which he took his revenge on all the local celebrities whose vanity or meanness had excited his ire, are alone sufficient to fill a volume. The Cateotts, Burgum, Barrett, and others of his patrons, figure in these satires, in imprudent yet discriminating caricature, along with mayor, aldermen, bishop, dean, and other notabilities of Bristol. But such satirical sallies were the mere sportive effusions of the boy, in which he thoughtlessly exposed even the foibles of his friends. Towards Lambert his feelings were of too keen a nature to find relief in such sarcasm. When he does give utterance to them, it is with a bitter sense of one deeply wronged. Doubtless the abilities of the attorney's clerk were widely different from what he had bargained for; but it is obvious that the boy whom he had received into his house was regarded by him with no more sympathy than any transient menial who drudged for hire. At length, in 1770, Chatterton's connexion with Lambert was brought to an abrupt close. Thus far the muse had rewarded him only by the pleasure of secret hours spent in her service. The very appreciation of his antique poems by the few to whom they had been communicated was accompanied by an utter ignoring of any capacity on the part of their real author; and every attempt to win recognition of his merits only subjected him to fresh slights. The ambition to be able to hold his place among his companions, in dress, and in the pastimes suited to their age, made him increasingly sensitive to his menial position, and tempted him to look to his pen for other returns than the pleasure derived from his romantic dream. Mr Cottle gives an extract from a letter written about this time, in which he curses the Muses, exclaiming, "I abominate them and their works. They are the nurses of poverty and insanity."

As the boy began to realize the practical necessities of life, and indulge in dreams of fame and fortune consequent on the recognition of his merits, he resolved to attempt the introduction of Rowley to the world. Accordingly in December 1768, while still only entering on his seventeenth year, he wrote to Dodsley, the London publisher, stating his ability to procure for him "copies of several ancient poems, and an interlude, perhaps the oldest dramatic piece extant, wrote by one Rowley, a priest in Bristol, who lived in the reigns of Henry VI. and Edward IV." To this letter he appended the initials of his favourite pseudonym, *Dunelmus Bristolensis*, but directed the answer to be sent to the care of Thomas Chatterton, Redcliffe Hill, Bristol. To this, as well as to another letter enclosing an extract from the tragedy of "Ælla," no answer appears to have been returned. The diplomacy of the romaneeer was only too characteristic of his inexperience; though we have a hint in the second letter of another and perhaps more practical idea for the publication of his antique drama. "If it should not suit you, I should be obliged to you if you would calculate the expense of printing it, as I will endeavour to publish it by subscription on my own account."

In the Rowley romanee, Chatterton pictures the old poet as the chaplain and confidential friend of Master Canynge, mayor of Bristol, builder of the church of St. Mary on Redcliffe Hill, and patron of all liberal arts,—who rejoiced in gathering round him a group of poets, and making them the sharers of his bounty. Rowley sends to him his verses from time to time, ever sure of some liberal acknowledgment in return; and Master Canynge supplies him with funds that he may expend them in travelling and collecting manuscripts for his library. Dean Milles, President of the Society of Antiquaries, and one of the most zealous maintainers of the genuineness of the imaginary Rowley, describes the old mayor and his literary associates as a parallel to Mæcenas with his three friends, Virgil, Horace, and Varus. No wonder, therefore, that Chatterton, conceiving the idea of finding sympathy and aid at the hand of some modern Canynge, bethought him of Horace Walpole, subsequently fourth earl of Orford. This patrician virtuoso loved to dally with the muses, and had made art and letters the business of his life. He professed extreme social liberalism, and not only indulged in a mediæval renaissance of his own, but was the reputed author of the *Castle of Otranto*, a spurious antique of times akin to those in which Chatterton had in like fashion delighted to revel. From the point of view of the inexperienced youth, the idea of finding in Walpole the patron of whom he dreamt was by no means an extravagant one. He accordingly addressed a letter to him, giving him an account of the Rowley poems and other MSS. as genuine antiques of the fifteenth century, and enclosing, as a specimen, a brief poem on Richard I.—probably his Eclogue styled "Nygelle," which extends to eight stanzas. To this Walpole replied with courteous acknowledgments. He characterized the verses as "wonderful for their harmony and spirit," and added, "Give me leave to ask you where Rowley's poems are to be had? I should not be sorry to print them; or at least a specimen of them, if they have never been printed." The courtesy of his correspondent tempted the poor boy to a more unreserved communication. He replied, enclosing additional specimens of antique verse, and telling Walpole that he was the son of a poor widow, and clerk to an attorney, but had a taste for more refined studies, and hinted a wish that he might help him to some more congenial occupation. Walpole's manner underwent an abrupt change. The specimens of verse had been submitted to his friends Gray and Mason, the poets, and pronounced modern. They did not thereby forfeit the wonderful harmony and spirit which Walpole had already professed to recognize in them. But he now coolly replied, advising the boy to stick to the attorney's office; and "when he should have made a fortune," he might betake himself to more favourite studies.

Walpole has been loaded with more than his just share of responsibility for the fate of the unhappy poet. That he shut his eyes to the merits of the wonderful poems sent to him by a boy of sixteen, and dwelling alone on the mystification with which they were palmed on him as genuine antiques, returned them to their author and thought no more about them, is what hundreds would do in like circumstances. Yet the literary fraud was no more than he himself had practised in his *Castle of Otranto*; and all the fame which he so greedily coveted was as nothing, compared with what he might have made his own, had he befriended the boy, of whom he admitted when too late "I do not believe there ever existed so masterly a genius."

Chatterton now abandoned the antique muse, turned his attention to periodical literature and the politics of the day, and exchanged *Felix Farley's Bristol Journal* for the *Town and County Magazine* and other London periodicals. Assuming the vein of Junius—then in the full blaze of his triumph—he turned his pen against the duke of Grafton, the earl of Bute, and the princess of Wales. It was while thus busied with politics and modern satire, that another and very different production was penned, which, whether written in jest or earnest, brought his Bristol career abruptly to a close. He had just despatched one of his political diatribes to the *Middlesex Journal*, when he sat down on Easter Eve 17th April

1770, and penned his "Last Will and Testament," a strange satirical compound of jest and earnest, in which he intimated his intention of putting an end to his life the following evening. Among his satirical bequests, such as his "humility" to the Rev. Mr. Camplin, his "religion" to Dean Barton, and his "modesty" along with his "prosody and grammar" to Mr. Burgum, he leaves "to Bristol all his spirit and disinterestedness, parcels of goods unknown on its quay since the days of Canynge and Rowley." In more genuine earnestness he recalls the name of Mr. Clayfield, a friend to whom he owed intelligent sympathy, and leaves to him "the sincerest thanks my gratitude can give,"—adding, with grave humour, the bequest of a full valuation to be paid to Mr. Clayfield, as his executor, of "whatever any person may think the pleasure of reading my works worth." According to his foster-mother's account, the will was purposely prepared in order to frighten his master into letting him go. If so, it had the desired effect. Lambert cancelled his indentures; his friends and acquaintance made him up a purse; and so, with light heart, and a bundle of manuscripts of rare worth by which he still fondly hoped that his fortune was to be achieved, he set forth, at the age of seventeen, to play his brief part as a man of letters in the great metropolis.

Chatterton was already known to the readers of the *Middlesex Journal* as a rival of Junius, under the nom de plume of Decimus. He had also been a contributor to Hamilton's *Town and County Magazine*, and speedily found access to the *Freeholder's Magazine*, another political miscellany strong for Wilkes and liberty. His contributions were freely accepted; and the sanguine youth flattered himself that his position was already established, and his fortune sure. He wrote accordingly in the most hopeful terms to his mother and sister, and spent the first money received by him in purchasing acceptable gifts for both. His pride and ambition were amply gratified by the promises and interested flattery of editors and political adventurers; Wilkes himself had noted his trenchant style, "and expressed a desire to know the author;" and Lord Mayor Beekford graciously acknowledged a political address of his, and greeted him "as politely as a citizen could." But of actual money he received but little. He was not only frugal, but abstemious, while he flattered himself with dreams of coming triumphs and ample recompense. His diligence was great, and his versatility wonderful. He could assume the style of Junius or Smollett, reproduce the satiric bitterness of Churchill, parody Macpherson's Ossian, or in graver mood ape the rhythmical niceties of Pope, or the polished grace of Gray and Collins. He wrote political letters, eclogues, lyrics, operas, and satires, both in prose and verse. He played in all ways the versatile mocking-bird, while still planning the resumption of his antique romanee, with the hope of winning thereby not only fortune but enduring fame.

In the month of June 1770—after Chatterton had been some nine weeks in London—he removed from Shoreditch, where he had hitherto lodged with a relative, to an attic in Brook Street, Holborn. His busy pen had dashed off songs, pasquinades, a burletta, an oratorio, satirical sketches, and political articles enough to fill more than one month's magazine. But for most of those the payment was delayed; and now state prosecutions of the press rendered letters in the Junius vein no longer admissible, and threw him back on the lighter resources of his pen. In Shoreditch, as in his lodging at the Bristol attorney's, he had only shared a room; but now, for the first time, in his new lodging, he enjoyed the delights of uninterrupted solitude. His bed-fellow at Mr. Wahnsley's, Shoreditch, noted that much of the night was spent by him in writing; and now that all restraint was removed the dawn frequently found him still at work. Fancy once more had free play; the romance of his earlier years revived, and he transcribed from an imaginary parchment of the old priest Rowley his "Excellent Balade of Charitye." This fine poem, perversely disguised in archaic language, he sent to the editor of the *Town and County Magazine*, and had it rejected.

The high hopes of the sanguine boy had begun to fade. He had not yet completed his second month in London, and already failure and starvation stared him in the face. Mr. Cross, a neighbouring apothecary whose acquaintance he had made, and who had been fascinated by his fine conversational powers, discerned ere long the evidence of the privations to which he was reduced, and repeatedly invited him to join him at dinner or supper; but he repelled the proffered hospitality. His landlady also, suspecting his necessity, pressed him to share her dinner, but in vain. "She knew," as she afterwards said, "that he had not eaten anything for two or three days." But he was offended at her urgency, and assured her that he was not hungry. Only a month before, he had written to his sister in the highest spirits, with talk of china, silver fans, and fine silks in store for them, and had actually sent them valued presents bought with his first earnings. But the needy political adventurers in whose service he had enlisted changed their tone when he began to press for payment for his contributions; and the note of his actual receipts, found in his pocket-book after his death, shows that Hamilton, Fell, and other editors who had been so liberal in flattery, had paid the inexperienced youth at the rate of a shilling for an article, and somewhat less than eightpence each for his songs; while

much which had been accepted was held in reserve, and still unpaid for. The beginning of a new month revealed to him the indefinite postponement of their publication, and with it of the prospect either of payment or of further demand for his labours. He had wished, according to his foster-mother, to study medicine with Barrett; and one of his companions specially refers to the charm which the practice of physic had for him. In his desperation he now reverted to this, and wrote to Barrett for such a letter as might help him to an opening as a surgeon's assistant on board an African trader. He appealed also to Mr Cateott to forward his plan, but in vain. The letters were written before the middle of the month, and he continued to hope against hope, as he awaited their replies. What these were we can only surmise. On the 24th of August 1770, he retired for the last time to his attic in Brook Street, carrying with him the poison which he there drank, after tearing into fragments whatever literary remains were at hand. In the morning he was found, with limbs and features distorted by his last convulsions, a ghastly corpse.

Thus perished by his own hand, in an obscure lodging in London, among strangers and in absolute want, a youth assuredly without his equal in that eighteenth century. He was only seventeen years and nine months old; yet he had already written poems which fill two ample volumes, and which now, upwards of a century after his death, command our admiring wonder for the rare evidence of genius and sustained power which they display. The intelligent labours of the Rev. W. W. Skeat have at length presented them in a form worthy of their unique merit, not only as evidence of fine poetic genius, but as an unparalleled example of youthful precocity displayed in spite of every disadvantage that poverty and adverse fate could interpose to prevent its display. Yet even now comparatively few know what a rich vein of romance and true poetry lies concealed under the antique guise of the Rowley poems, or how singular is the study which they involve. The best of his numerous productions, both in prose and verse, require no allowance to be made for the immature years of their author, when comparing him with the ablest of his contemporaries. Yet he was writing spirited satires at ten, and he produced some of the finest of his antique verse before he was sixteen years of age. He pictures Lydgate, the monk of Bury St Edmunds, challenging Rowley to a trial at versemaking, and under cover of this fiction, produces his "Songe of Alisa," a piece of rare lyrical beauty, worthy of comparison with any antique or modern production of its class. Again, in his "Tragedy of Goddwyn," of which only a fragment has been preserved, the "Ode to Liberty," with which it abruptly closes, is a wonderful specimen of bold imagery which may claim a place among the finest martial lyrics in the language.

The collection of poems in which such specimens occur furnishes by far the most remarkable example of intellectual precocity in the whole history of letters; nor is it the least among all the notable features which distinguish the boy's writings, that, from first to last, he consistently maintained his romance of Canynge and Rowley through all the diverse scenes of verse and prose in which those imaginary characters are made to figure. The age at which he died, before he had even reached manhood, adds to the tender pity which his fate awakens even now, upwards of a century after his death. Collins, Burns, Keats, Shelley, and Byron all awaken sorrow over the premature arrestment of their genius; but the youngest of them survived to his twenty-fifth year, while Chatterton was only seventeen when he perished despairingly in his miserable garret.

The death of Chatterton attracted little notice at the time; for the few who then entertained any appreciative estimate of the Rowley poems regarded him as their mere transcriber. He was interred in a burying ground attached to Shoe Lane Workhouse, in the parish of St Andrew's, Holborn, which has since been converted into a site for Farringdon Market. But a story has been current from an early date, and credited by some trustworthy investigators, that the body of the poet was recovered through the intervention of one of his London relatives, and secretly interred by his uncle, Richard Phillips, in Redcliffe Churchyard. There a monument has since been erected to his memory, with the appropriate inscription, borrowed from his "Will," and so supplied by the poet's own pen—"To the memory of Thomas Chatterton. Reader! judge not. If thou art a Christian, believe that he shall be judged by a Superior Power. To that Power only is he now answerable." (D. W.)

CHAUCER, GEOFFREY (c. 1340-1400). There are few fields of research in which antiquarians, from Speght to Furnivall, have laboured so zealously and successfully as the life of Chaucer. The secret of their success has been that Chaucer was more actively engaged in public affairs than any poet of celebrity since his time, and has consequently left many traces in official records. The chief biographical fact known to Speght was that Chaucer gave evidence in

a case tried at Westminster in 1386 touching the right of Lord Scrope to bear certain arms, and then deposed that he was "forty years old and upward," and had borne arms for twenty-seven years. A casual fact of this sort offered no clue to further investigation; but the fact that Chaucer received from Edward III. a pension of twenty marks was more suggestive. This clue was first energetically followed up by Godwin, the author of *Caleb Williams* and *Political Justice*, who searched diligently through several records, chiefly the Patent, Close, and French Rolls, for other notices of Chaucer's name, and succeeded in enriching his biography of Chaucer, published in 1804, with various important particulars. He was followed by Sir Harris Nicolas, who made an exhaustive examination of the Issue Rolls of the Exchequer, and published the results in 1843. Another determined search through records which Godwin and Nicolas had shrunk from was made in 1873 by Mr Furnivall, and this also resulted in several important finds.

It is to Mr Furnivall that we are indebted for finally settling the parentage of Chaucer. Speght in the course of his researches had hit upon the name of one Richard Chaucer, a vintner, who died in 1348, and made a bequest to the church of St Mary Aldermary. Merely on the ground of the name, Speght supposed this to be the father of Chaucer; but Urry and Tyrwhitt, in the 18th century, disputed this, and wished to give the poet a higher lineage, because in the grant of a pension made to him in 41 Edward III. he was described as "valettus noster." Mr Furnivall settled the question by bringing to light a deed dated 1380, in which Chaucer, relinquishing his right in a house belonging to his father, described himself as "the son of John Chaucer, vintner." By other documents this John Chaucer is shown to be the son of Speght's Richard. It is thus established that both the poet's father and his grandfather were London vintners. The precise date of his birth has not been ascertained. The accepted date till lately was 1328. The difficulty with this date was his being described as "forty years and upwards" in 1386, and of late opinion has inclined to 1340 as a more probable year. This is favoured by the discovery that the poet was Richard Chaucer's grandson and not his son, and fits in better with the facts than 1328.

How Chaucer was educated, whether like "Philogenet," the name which he assumes in the *Court of Love*, he was "of Cambridge clerk," and how he was introduced to the notice of the court, is left to conjecture. His name occurs in the household book of the wife of Prince Lionel, second son of Edward III., in 1357, probably, Mr Furnivall conjectures, as a page. He bore arms in Edward III.'s invasion of France in 1359, John Chaucer being also in the expedition, probably in connection with the commissariat. There was little fighting in that expedition, the ravages of the English for several years before having left little to fight for; but in the course of a disastrous retreat, compelled rather by hunger than by martial force, Chaucer was taken prisoner. In 1360 the king paid £16 for his ransom. From 1360 to 1366 there is a gap in the record of his life; but in the latter year his name occurs in a list of the members of the royal household as one of thirty-seven "esquires" of the king, who were to receive a gift of clothes at Christmas. By this time also he would seem to have been married, if the Philippa Chaucer, one of the demoiselles of Queen Philippa, who in 1366 was granted a yearly pension of ten marks, was, as is most probable, his wife (see the discussion of the question in Sir H. Nicolas's memoir). In 1367 Chaucer himself received a pension of twenty marks from the king, being described as "dilectus valettus noster." To show that in being courtier and scholar he had not ceased to be soldier, he took part in another inglorious expedition against France in 1369, in

which from the Fabian tactics pursued by the French king there was little opportunity for distinction. He was back in London towards the end of 1370, and henceforward devoted himself to more peaceful pursuits. His talents for diplomacy and his acquaintance with commerce were recognized by the crown. In 1372 he was despatched to Genoa as a commissioner to arrange a commercial treaty with the Genoese. About this embassy much has been written on the supposition that he may have made the acquaintance of Petrarch in the course of his visit to Italy. Whether in recognition of his services or on other grounds, he received on his return, in 1374, the grant of a pitcher of wine daily; and soon after, in further evidence of the royal favour, he was appointed comptroller of the customs and subsidy of wools, skins, and tanned hides in the port of London. In 1376 he was associated with Sir John Burley on some secret service, the nature and place of which are not known, and in 1377 he was sent on the secret mission to Flanders. And it was not merely in commercial matters that the poet was considered serviceable; in 1378, after the accession of Richard II., he was attached to a mission sent into France to negotiate a marriage for the young king. His fortunes continued steadily to improve; with his pension of twenty marks from the king, £10 from the duke of Lancaster, his allowance for robes as one of the king's esquires, his salary as comptroller, his payments for occasional services, his pitcher of wine (commuted in 1378 into an annuity of twenty marks), and his wife's pension, he had no reason to complain that his genius was neglected. The wonder was that his genius was not smothered. His employment as comptroller was not a sinecure; he was bound to write the rolls of his office with his own hand, and he had to be continually present at his office, not having the option of appointing a deputy. Apparently as he rose in the world he was allowed to make an easier arrangement; in 1382 he was appointed comptroller of the petty customs of the port of London, with the privilege of appointing a deputy, and in 1385 he was allowed to appoint a deputy for the other comptrollership. In 1386 he touched the summit of his fortune, being returned to Parliament as a knight of the shire of Kent. But that was an unfortunate year for him; his patron, John of Gaunt, lost his ascendancy at court, and a commission which sat to inquire into the abuses of the preceding administration superseded Chaucer in his two comptrollerships. In the course of two years he was obliged to transfer his annuities to another man, probably selling them for a sum of ready money. The return of Lancaster to power in 1389 again brightened his prospects; he was appointed clerk of the king's works, and four years afterwards obtained a grant of an annuity of £20. How much he wanted this assistance appears from the fact that he was several times obliged to apply for small portions of it in advance. When Bolingbroke came to the throne in 1399 he gave the old poet an additional annuity of forty marks, which came in time to comfort the last year of his life. The minutes of his pension cease in 1400, and, according to the inscription on his tomb, he died on the 25th of October of that year.

These are the main facts of Chaucer's life as brought to light by successive investigators, and they form a tolerably complete outline biography, more complete than Spenser's or Shakespeare's. They are significant facts, throwing light on the singularly varied circumstances, aptitudes, and occupations of the man, supplementing in a really substantial way what may be gathered from his works. They show that Chaucer was not merely a poet and a scholar, deeply read in what then passed for science and philosophy, as well as in the rich literature of his poetical predecessors, but a soldier, a courtier, a man of business, familiar from

the circumstances of his birth and subsequent rise in position with all sides of the life of his time, ready to undertake any kind of employment that his powerful patrons chose to obtain for him,—comptrollership of customs, secretarieship of an embassy, diplomatic commissionership, guardianship of a minor. Mr Furnivall has also discovered that, rather late in life, he was charged with being concerned in the "raptus" (abduction, probably) of a girl, which would show that he was willing to undertake more questionable services, unless the "raptus" was for his own benefit. Great caution must be observed in trying to fill up from hints in his poems the gaps in the documentary facts of his biography,—great caution, that is, if we wish to get at the truth and not merely to speculate for the sake of speculating. Antiquarian speculators are usually more distinguished for fancy than imagination. They catch at hints and push them to conclusions without having imagination enough to take account of qualifying considerations. Thus it has often been taken for granted that in the description of the poet of the *Canterbury Tales*, we have an authentic portrait of Chaucer himself. The poet is a very quiet unobtrusive man, and the Host, master of the ceremonies, suddenly casts his eye on him, and addresses him in his bullying way:—

What man art thou? quod he.
Thou lookest as thou wouldest find an halle,
For ever upon the ground I see thee stare.
Approche near, and looke merrily.
Now wate you, sirs, and let this man have space.
He in the waist is shapen as well as I;
This were a puppet in an arm to embrace
For any woman, small, and fair of face.
He seemeth elvish by his countenance,
For unto no wight doth he dalliance.

There is no reason to suppose that this quaint, shy little figure was any more like Chaucer than the *Spectator* was like Addison or Steele. The allusion to his waist, coming from the burly host, is evidently jocular, and the whole picture is in all likelihood a humorous description of the opposite of Chaucer's own appearance. We must be particularly careful in accepting literally the statements of a writer one of whose favourite veins of humour, appearing in every one of his works, is self-depreciation. We should remember that Chaucer wrote for a limited audience, all of whom knew him personally, and for whose amusement he was in the habit of making comical allusions to himself. His jokes were more of the nature of family jokes than we are now accustomed to in writings intended for wide and promiscuous circulation. When he made the eagle in the *House of Fame* complain of his being heavy to carry, or promise to make him the butler of the gods, or append to the statement that he lived like a hermit, the qualification—"although thine abstinence is little," or remind him that he had had no personal experience of love, he knew that these little jests at his own expense would be fully appreciated by his few readers. The extreme of frivolous conjecture is reached when it is supposed that his wife was a termagant because he "chaffs" women frequently. His graceful and chivalrous compliments to women are quite as frequent as his chaff. There is, indeed, one passage in the *House of Fame* which is pretty clearly intended for his wife, that where the eagle cries "awake" to him—

Right in the same voice and steven (sound)
That useth one I coulde nevern (name).

But if it had been anything more serious than commonplace conjugal banter, he would hardly have dared to circulate it. A conjecture of an equally frivolous kind is that he was unmarried in 1369, because in that year he spoke of having suffered for eight years pangs which none but one could heal. The pangs may have been matrimonial pangs, or pangs of poverty, or purely imaginary pangs.

officially becoming in the poet-narrator ; but Mr Furnivall is so convinced that the poet's sickness was a real love-sickness, and that he was not then married to the queen's demoiselle Philippa Chaucer, that he accounts for this lady's name by supposing her to have been Chaucer's cousin.

A similar inelasticity of conjecture appears in the grounds on which certain of the works commonly attributed to Chaucer are rejected as spurious. The *Testament of Love*, the *Assembly of Ladies*, and the *Lamentation of Mary Magdalene* bear no internal marks of being Chaucer's, and are now universally rejected ; but of late some commentators have adopted a test of genuineness which would deprive us of several works which are in no respect unworthy of Chaucer's genius. It is known from Chaucer's own statement in the undisputed *Legend of Good Women* that he translated the *Roman de la Rose*, but Mr Bradshaw refuses to believe that the extant translation, of which we have only one 15th century manuscript, can be his, because its rhymes do not conform to a rhyme-test which Chaucer observed in works which are undoubtedly his. The extant *Romance of the Rose* admits the adverbial *ly* to rhyme with the adjectival or infinitival *-ye*, and it cannot be Chaucer's because *y* is never allowed to rhyme with *ye* in the *House of Fame* and the *Canterbury Tales*. For the same reason—no other of any shadow of validity has yet been adduced—the *Court of Love*, which Mr Swinburne calls "that most beautiful of young poems," and the *Flower and the Leaf*, which Dryden and Hazlitt have praised and quoted as a choice example of the poet's genius, have also been pronounced to be spurious. We cannot give up such poems unless more urgent reasons are advanced for their confiscation. They cannot be set aside as spurious so long as their variation from the rhyming rule, which the commentators have shown much ingenuity in detecting, can be explained in any reasonable way. There is no getting over the plain question which every one asks when first told that they are not Chaucer's. If they are not his, who else could have written them ? Is it conceivable that the name of the writer of such works could have been utterly unknown in his own generation, or if known could have been by accident or design so completely suppressed ? If he deliberately tried to palm them off as Chaucer's upon the transcribers, would not this rule of rhyme have been precisely the sort of mechanical likeness which he would have tried to preserve ? The *Court of Love* we have special reasons for declining to give up. It might be argued that, though the *Flower and the Leaf* bears internal marks of being Chaucer's, although its picturesque richness, its tender atmosphere, and the soft fall of its words are like his, yet it is easy to grow the plant once you have the seed, and it may be the work of an imitator. The *Flower and the Leaf* professes to be written by a lady, and there may have been at the court some wonderful lady capable of it, although it passed in the monkish scriptorium as Chaucer's. But there is some external evidence for the authenticity of the *Court of Love*, which also contains traces of Chaucer's most inimitable quality, his humour. Mr Minto has put forward some minor considerations for believing this to be Chaucer's (*Characteristics of English Poets*, p. 22), but the strongest fact in its favour is that the *Court of Love* was imitated by James I. of Scotland in the *King's Quhair*, and that in paying the customary compliment to his poetical masters, he mentions no names but Lydgate and Gower, who were clearly incapable of writing the poem, and Chaucer. James's captivity in England began five years after Chaucer's death, and it is simply inconceivable that he could have attributed the *Court of Love* to Chaucer in ignorance, and without having heard a whisper of its real authorship. If, indeed, this rhyme-test were

absolute, we should have to treat these other considerations as inexplicable difficulties and submit. But when we remark that all the poems in which *y ye* rhymes occur are earlier works of Chaucer's, if they are his at all, bearing the touch of his hand but wanting the sustained strength of his mature workmanship, and when we remember that the *y ye* rhyme was the common practice of his predecessors, a very simple explanation of the rhyme difficulty becomes apparent. Chaucer adhered to the practice of his predecessors till he felt strong enough to impose upon himself a restriction of his own devising.

At what periods of his life Chaucer wrote his poetry, we have no means of ascertaining. There are no manuscripts of any of his works that can be referred to his own time ; the earliest of them in existence are not supposed to have been written till several years after his death. The only one of his works of which the date is fixed by an external circumstance is the *Book of the Duchess* ; if, as is taken for granted, this was written to commemorate the death of the wife of his patron John of Gaunt, its date is 1369. Chaucer, if born in 1340, would then have been twenty-nine, and there is none of his extant works, except the translation of the *Romance of the Rose*, and the *Dream* (which we hold to be Chaucer's, though its authenticity is not worth contending for), which can be confidently assigned to an earlier period. Philogenet, in the *Court of Love*, professes to be eighteen, but this is not the slightest reason for concluding that Chaucer was that age when he wrote it. The *Book of the Duchess* is certainly not very mature work for a poet of twenty-nine, and it is probable that Chaucer did not cultivate the art, as he certainly did not develop the faculty, till comparatively late in life. The translation of the *Romance of the Rose* is to all appearance the earliest of his surviving compositions. If we may judge from his evident acquaintance with dry studies, and his capacity for hard business work, the vintner's son received a scholastic training in the *trivium* and *quadrivium* which then formed the higher education. If he had been nurtured on troubadour love from his youth up, it is exceedingly unlikely that he would afterwards have been able to apply himself to less fascinating labours. His study of mathematics and astronomy in his old age for the benefit of "little Lewis, his son," looks like a return such as we often see in age to the studies of youth. But, indeed, he can hardly be said ever to have lost his interest in such studies, for in his theory of sound in the *House of Fame* and his description of alchemical processes in the Canon's Yeoman's Prologue he shows a genuine scholar's interest in the dry details of learning. His knowledge of the *Trouvère* and *Troubadour* poetry, from which his genius received its impulse, probably began with his introduction, however that was brought about, to court society. He was about seventeen at the date of the first mention of his name as attached to the household of Prince Lionel. It is permissible to conjecture that he had French poets to beguile his captivity in France a few years afterwards.

Professor Ten Brink divides Chaucer's work into three periods :—a period of French influence, lasting up to 1372-3, the date of his visit to Italy ; after that a period of Italian influence, lasting up to 1387, the supposed date of his *House of Fame* ; finally, a period of mature strength and originality, in which he pursued the bent of his own genius. Not much is gained by this division into strict periods. It is obvious enough that, in the *House of Fame*, the *Legend of Good Women*, and the general plan of the *Canterbury Tales*, Chaucer strikes out more unmistakably a path for himself, and exhibits a maturer power, a more masterly freedom of movement than in his earlier works, but there profitable division ends. To erect a period of Italian influence, implying that at any time the stimulus

that Chaucer received from Italian sources was at all comparable to the stimulus he received from French sources, is most misleading. The difference between the *Book of the Duchess* and the *House of Fame*, or between the *Court of Love* and *Troilus and Cressida* is not to be explained by an influx of Italian influence; it is part of the self-governed development, the spontaneous expansion of his own mind. As he went on writing, his powers continued to expand, and to take in materials and suggestions from all quarters open to him, French, Italian, or Latin. Comparing the *Troilus*, the raw material of which is taken from Boccaccio's *Filostrato*, with his *Romance of the Rose*, we can trace no change in method or in spirit fairly attributable to Italian influence. In both translations he shows a bold independence of his originals; they are not so much translations as adaptations. He does not imbibe the spirit of Guillaume de Lorris or Jean de Meun in the one and the spirit of Boccaccio in the other; he boldly modifies all three to bring them into harmony with his own conceptions of love's laws, and in both his so-called translations there is the same high spirit of chivalry and the same tender worship and kindly mockery of woman. Where he chiefly shows advance of strength, apart from the mere technical workmanship, is in his grasp of character; and that is a clear development on the lines of his earlier conceptions and not a new acquisition. His *Cressida* and his *Pandarus* were not the *Cressida* and *Pandarus* of Boccaccio; they are regenerated by him and developed till they become figures that might have moved in his own *Court of Love*. He held the knightly and "gentle" character too high to adopt Boccaccio's conceptions. In the method also, *Troilus* has a close affinity with Chaucer's earlier work and his first models. *Troilus'* pursuit of *Cressida* is the pursuit of the *Rose* over again in the concrete. The greater subtilty of the stages is due to the increased strength of the narrator's faculty.

M. Sandras is in the main right as to the extent of Chaucer's obligations to French sources, although he fails to recognize the forceful individuality of the man. Chaucer was really an English *trouvère*, thoroughly national, English in the whole texture of his being, but a *trouvère*. We must not allow our conviction of his loyalty to his own English nature to blind us to the fact that he was a poet in the school of Guillaume de Lorris; nor on the other hand must we allow the peculiar extent of his obligations to his predecessors in the school to obscure the fact that he was an original poet. M. Sandras is a special pleader for one side of the case, and naturally presses unfairly against the other. Chaucer, writing in a different language from his masters, was at liberty to borrow from them more literally than he could have done if he had written in their language; but though M. Sandras proves with superfluous completeness that he freely appropriated from them not merely stories and hints of stories, but narrative methods, phrases, images, maxims, reflections,—not only treated their works as quarries of raw material, but adopted their architectural plans, and even made no scruple of seizing for his own purposes the stones which they had polished, still he so transmuted the borrowed plans and materials that his works are original wholes unmistakably stamped with his own individuality. Whatever he appropriated, whether ore or wrought metal, all passed through his own alembic, and his moulds were his own, though shaped according to the fashion of the school. The very affluence of Chaucer's pages, their wealth of colour, of tender and humorous incident, of worldly wisdom, is due to his peculiar relations to his predecessors, to the circumstance which enabled him to lay them so royally under his feet. He was not the architect of his own fortune, but the heir of a family which for generations had been

accumulating wealth. Edward III.'s spoliation of the French was nothing to Chaucer's, and the poet had this advantage, that his appropriations neither left the spoiled country desolate nor corrupted the spoiler.

"The ground-work of literary genius," Mr Matthew Arnold says, "is a work of synthesis and exposition, not of analysis and discovery; its gift lies in the faculty of being happily inspired by a certain intellectual and spiritual atmosphere, by a certain order of ideas, when it finds itself in them, of dealing divinely with these ideas, presenting them in the most effective and attractive combinations—making beautiful works with them, in short." The poet's constructive power must have materials, and ideas round which materials accumulate. The secret of the richness and enduring character of Chaucer's work is that he had a fruitful idea ready to his hand, an idea which had been flowering and bearing fruit in the minds of two centuries, which had inspired some later songs and tales, which had been illustrated, expounded, formulated by every variety of native invention and critical ingenuity. Chivalrous love had been the presiding genius, the inspiring spirit of several generations of poets and critics when Chaucer began to write. Open any of his works, from the *Court of Love* down to the *Canterbury Tales*, and you find that the central idea of it is to expound this chivalrous sentiment, either directly by tracing its operation or formulating its laws, or indirectly by setting it off dramatically against its counterpart, the sentiment of the villain or churl. Gradually as years grew upon him, and his mind assumed more and more its natural attitude of descriptive impartiality, he became less a partizan of the sentiment, more inclined to view it as one among the varieties of human manifestation, but never to the last does he become wholly impartial. Not even in the *Canterbury Tales* does he set the churl on a level with "the gentles." Thoroughly as he enjoyed the humour of the churl, freely as his mind unbent itself to sympathize with his unrestrained animal delights, he always remembers, when he comes forward in his own person, to apologize for this departure from the restraints of chivalry.

The very opposite of this is so often asserted about the *Canterbury Tales* that it almost has a paradoxical air, although nothing can be more plain to any one who takes the trouble to read the tales observantly. It has been said to be the crowning merit of Chaucer that he ignores distinctions of caste, and that his pilgrims associate on equal terms. It should be noticed, however, in the first place, that in the Prologue, he finds it necessary to apologize for not "setting folk in their degree," "as that they should stand;" and, in the second place, that although he does not separate the pilgrims according to their degrees in the procession, yet he draws a very clear line of separation between them in the spirit of their behaviour. At the outset of the pilgrimage the gentles are distinctly so mentioned as taking a sort of corporate action, though in vain, to give a more decorous aspect to the pilgrimage. When the Knight tells his tale, it is loudly applauded by the whole company, but the poet does not record their verdict indiscriminately; he is careful to add, particularly by "the gentles every one." And though all applauded the tale, the more vulgar and uproarious spirits were somewhat restive under its gravity, the host called for a merry tale, and the Pardoner eagerly stepped forward to comply with his request. But "the gentles" interposed, and began to cry that they must have no ribaldry; "tell us," they said, "some moral tale that we may learn." And the gentles would have carried their point if the Miller, as the poet is most careful to make clear, had not been so drunk that he insisted upon telling a noble tale that he knew, and would forbear for no man. Chaucer is profuse in his apologies for introducing such a tale; it was a churlish

tale, he admits, told in a churlish manner, and he does not wish to be responsible for it.

"Every gentle wight I pray
For Goddes love, deemeth not that I say
Of evil intent; but for I must rehearse
Their tales all, be they better or worse,
Or elles falsen some of my matter"

If gentle readers do not like it, they may turn over the leaf, and choose another tale; there is plenty "of storial thing that toucheth gentillesse." They must not blame him for repeating this churlish tale; "the Miller is a churl, ye know well this," and such tales are in his way. Gentle readers must not take it too seriously; "men should not make earnest of game;" it is, after all, only for their amusement that he thus exhibits to them the humours of the lower orders.

Such is the elaborate apology that Chaucer makes for introducing into his verse anything inconsistent with the sentiments of chivalry. It may be said that it is all a humorous pretence; and so no doubt it is, still it is characteristic that the pretence should be of so courtly a tone. All through the *Canterbury Tales* Chaucer is very careful to remember that he was writing for a courtly audience, studious to guard against giving offence to the chivalrous mind. He contrives that the gentles shall mix with the churls without sustaining any loss of dignity; they give the churls their company, and with polite complaisance let them have their own gross will, but they never lay aside the restraints of their own order. Every here and there is some trace of deference to them, to show that their ribald companions have not wholly forgotten themselves, and are only receiving a saturnalian licence for the time. Nothing is done to throw any disrespect on the gentle order; its members—the Knight, the Squire, the Monk, the Prioress, the Second Nun; and the professional men—the Lawyer, the Doctor, the Clerk—admit no ribaldry into their tales, and no ribald tales are told about them. The ribaldry is confined to the meaner members of the company,—the Reeve, the Miller, the Friar, the Summoner, the Wife of Bath; the narrators as well as the subjects of the ribald tales are of churlish and not of gentle position.

The *Canterbury Tales* are really in their underlying design an exposition of chivalrous sentiment, thrown into relief by contrast with its opposite. The spirit of chivalry is the vital air of all Chaucer's creations, the rain, the wind, and the sun which have quickened their germ and fostered their growth. We to whom the chivalrous spirit, at least in the fantastic developments of its vigorous mediæval youth, is an historical thing are apt to overlook this. There is so much on the surface of Chaucer's poems, such vivacity of movement, such tender play of feeling, such humour, such delight in nature, in green leaves and sweet air, sunshine and bird singing, that few of us care to look beneath. The open air, on the breezy hillside or by the murmuring brook, seems the only proper atmosphere for such a poet. There, no doubt, with sun and wind contending playfully to divert us from the printed pages, there perhaps more than anywhere else, Chaucer is a delightful companion; but it is the duty of the dry-as-dust critic to remind us that Chaucer's sweet verses were first read under wholly different conditions, in tapestried chambers, to the gracious ear of embroidered lords and ladies. It was from such an audience that Chaucer received in a vapour what he poured back in a flood. This is the secret of his exquisite courtliness of phrase, his unfailing tone of graceful deference, his protestations of ignorance and lack of cunning, his tender handling of woeful love-cases, the gentle playfulness of his satire, the apologetic skill with which he introduces a broader and more robust humanity into his verse. If you place yourself within the circle for which

the poet wrote, you see the smile play on sweet lips as he proceeds; you see the tear gather in the eye; you see the needle laid aside, as the mind of the fair listener is transported to the poet's flowery mead, or plied more briskly as she bends over her work to conceal her laughter at his more vulgar adventures. It was because Chaucer wrote for such an audience that his picture of the life of the time, various and moving as it is, is so incomplete on one side.

There was more than romancing in green fields and Canterbury pilgriming in the travelled times in which Chaucer lived; there were wars, plagues, insurrections, much misery and discontent. But for the disagreeable side of the 14th century we must go to the writer of *Piers the Plowman*; we find little trace of it in Chaucer. The outside of the walls of the Garden of Mirth is painted with horrible and squalid figures,—Ire, Envy, Covetice, Avarice, Felony, Villany, Sorrow, Eld, and Poverty; but no such figures are admitted within the gates; the concierge is Idleness; the chief inmates are Love, Sweetlooking, Beauty, Richesse, Largesse, Franchise, and Courtesy; and Mirth and Gladness are the master and mistress of the ceremonies.

All Chaucer's works are steeped in the nectar of the court; the perfume of chivalrous sentiment breathes from them all. It is impossible, as we have said, to determine strictly the order of their composition, though it is very easy to distinguish his earlier from his later work. There is a passage in the Prologue to the *Legend of Good Women* which settles the position of that poem. The poet there pretends to have an interview with the king and queen of love, as he is out on a May morning to worship the daisy. The king challenges his worthiness to do homage to this his own flower, and upbraids him with having translated the *Romance of the Rose*, which (in its second part at least) is a heresy against love's law, and also with having told the story of Cressida, and thrown discredit on women. But the queen of love, Alceste, speaks up for the poet; perhaps, she pleads, he was ordered to do these translations and durst not refuse; and he had done good service by extending the praise of love among the unlearned folk, for—

"He made the book that light the house of Fame,
And eke the death of Blanche the Duchess,
And the Parliament of Fowles as I guess,
And all the love of Palamon and Arcite,
Of Thebes, though the story is knownen lité;
And many a hymne for your holy days
That lighten Ballads, Roundels, Virelays."

The translation of the *Romance of the Rose* was probably the first of these works. It may have been written soon after or during his captivity in France, when he was a youth of twenty, but there is no appreciable difference of style between it and the *Book of the Duchess*, which if it commemorates, as there is every reason to believe, the death of the first wife of John of Gant, must have been written after 1369, when Chaucer was twenty-nine. The idea of writing in the vulgar tongue may have been suggested to him by the example of Dante. The *House of Fame* is probably later than the *Book of the Duchess*. The *Court of Love* is not mentioned by name in the above list, but it may be referred to in the following lines of the prologue:—

"Hast thou not in a book lyeth in thy chest
The grete goodness of the Queen Alceste
That turned was into a dayeseye?"

Alceste is, under Venus, the lady and queen of the Court of Love. It is easy to conceive why Chaucer should have kept the *Court of Love* in his chest. The tide of Puritanic religious sentiment which was destined to sweep into temporary oblivion the airy structures of the chivalric imagination had already in the middle of Chaucer's life begun to rise. In the *Court of Love* he fully accepted the troubadour notion of love and marriage,

making the husband the natural enemy of the lover; and he may have had to accommodate himself to the taste of the Fair Maid of Kent, the widow of the Black Prince, the Alceste of the time, and put his poem out of sight, only pleading that even in it he had paid homage to "the greatest goodness of the Queen Alceste."

There is no good edition of Chaucer, not even a good text. The only text or rather collection of texts that the Chaucerian scholar would think of using is the valuable parallel six-text edition, published by the *Chaucer Society*. For the general reader one text is about as good as another; there is little to choose between Tyrwhitt's, Bell's, and Dr Morris's text in the Aldine edition. (W. M.)

CHAUDÉS-AIGUES, an old town of Upper Auvergne in France, in the department of Cantal, 17 miles S.S.W. of St Flour. It is celebrated for its hot mineral springs, which vary in temperature from 135° to 177° Fahr., and at their maximum rank as the hottest in France. The water, which is very slightly alkaline, is employed not only for medical purposes, but also in the washing of fleeces, the incubation of eggs, and various other economic applications; and it furnishes a ready means of heating the houses of the town during winter. In the immediate neighbourhood is the cold chalybeate spring of Condamine. The warm springs were known to the Romans, and are mentioned by Sidonius Apollinarius. The population of the town is about 2000.

CHAUMONT, a town of France, the capital of the department of Haute Marne, on an eminence between the Marne and the Suize, 145 miles S.E. of Paris by the railway, which here crosses a fine viaduct. It is the seat of tribunals of primary instance and commerce, is tolerably well built, and has an elegant town-hall, a court-house, a communal college, a hospital, a theatre, a public library, and a botanical garden. A single tower remains of the Castle of Haute Feuille, which belonged to the counts of Champagne, and there is a triumphal arch erected by Napoleon I. and finished by Louis XVIII. The church of Saint Jean-Baptiste, a building of the 13th century, and the chapel of the old college of the Jesuits, are classed among the historic monuments of France. Coarse woollens, hosiery, and gloves are manufactured in the town; and there is a considerable trade in the iron and iron-wares of the department. The rise of Chaumont into importance dates from 1190, when it received a charter from the counts of Champagne. In the 13th century it became the seat of a provost; and in the 16th it was surrounded with fortifications. It was here that the treaty of 1814 was concluded by which England, Austria, Russia, and Prussia formed an alliance against Napoleon. Population in 1872, 8474.

CHAUNY, a town of France, in the department of Aisne, 20 miles W.N.W. of Laon, situated partly on the right bank of the Oise and partly on an island at the commencement of the canal of St Quentin. It has some trade in cider, linen cloth, and hosiery, and is a dépôt for coals from Flanders and glass mirrors from St Gobain. Population in 1872, 8831.

CHAUVIN, ÉTIENNE (1640–1725), a celebrated minister of the Reformed religion, was born at Nîmes. At the revocation of the Edict of Nantes he retired to Rotterdam; and in 1695 the elector of Brandenburg appointed him professor of philosophy at Berlin, where he enjoyed considerable reputation as a representative of Cartesianism, and as a student of physics. His principal work is a laborious *Lexicon Rationale, sive Thesaurus Philosophicus*, which he published at Rotterdam in 1692, and of which a new and enlarged edition was printed at Leuwarden in 1703. He also wrote *Theses de Cognitione Dei*, and started the *Nouveau Journal des Savants* (1694–98). Chauvin died in 1725.

CHAUX DE FONDS, a town of Switzerland, in the canton of Neuchâtel, and ten miles N.W. of the city of that name, at a height of 3200 feet above the level of the sea, in the rugged and narrow valley of the Jura. Rebuilt after the conflagration of 1794, the town has a handsome and pleasant appearance, and its public buildings include a church with vaulted roof, extensive schools, and a theatre. There are also some peculiar subterranean mills turned by a stream before it sinks into the ground. The principal trade is the manufacture of watches, which are turned out at the rate of 150,000 annually; but gilding, enamelling, and carving are also carried on, as well as the manufacture of scientific and musical instruments. The watch trade was introduced in 1679, and is conducted on the principle of the division of labour. Population in 1872, 19,930.

CHAVES, a town of Portugal, not far from the frontier, in the province of Tras-os-Montes, on a plain near the right bank of the Tamega, which is here crossed by a fine old Roman bridge of eighteen arches. It was formerly one of the principal fortifications in the country, and in fact derives its present name from its forming the "keys" or "chaves" of the north. It has hot saline springs which were known in ancient times as the *Aque Fluvia*. In one of its churches is the tomb of Alphonso I.; and it gave the title of marquis to Pino de Fonseca, the gallant supporter of Dom Miguel. Population formerly about 20,000, now 4870.

CHAZELLES, JEAN MATHIEU DE (1657–1710), a French mathematician and engineer, was born at Lyons in 1657. He was employed for some time by Cassini in measuring the meridian, and afterwards taught mathematics to the duke of Mortemar, who procured him the preferment of hydrographic professor for the galleys of Marseilles. In 1686 Chazelles went on board the galleys in their campaigns, and kept his school at sea. He was sent to the west coast in July 1689 to examine the practicability of so contriving galleys that they might live upon the ocean, and be employed to tug the men-of-war when becalmed; and having set sail with fifteen galleys from Rochefort, he cruised as far as Torbay, in Devonshire, and took part in the descent upon Teignmouth. On his return he published his observations, with maps of the coasts and harbours he had visited. These maps were inserted in the *Neptune Français*, published in 1692. In 1693, Monsieur de Pouchatrain, secretary of state for the marine, engaged Chazelles to publish a second volume of the *Neptune Français*, which was to include the hydrography of the Mediterranean. For this purpose he passed through Greece, Turkey, and Egypt. When in Egypt he measured the pyramids, and finding that the angles formed by the sides of the largest were in the direction of the four cardinal points, he concluded that this position must have been intended, and also that the poles of the earth and meridians had not deviated since the erection of these colossal structures. Chazelles likewise made a report of his voyage in the Levant, and another concerning the position of Alexandria. He was made a member of the Academy in 1695, and died in 1710.

CHEDUBA, an island in the Bay of Bengal, situated ten miles from the coast of Aracan, between 18° 40' and 18° 56' N. lat., and between 93° 31' and 93° 50' E. long. It extends about 20 miles in length from north to south, and 17 miles from east to west, and its area of 250 square miles supports a population of 10,000. The channel between the island and the mainland is navigable for boats, but not for large vessels. The surface of the interior is richly diversified by hill and dale, and in the southern portion some of the heights exceed a thousand feet in elevation. There are various indications of former

volcanic activity, and along the coast are earthy cones covered with green-sward, from which issue springs of muddy water emitting bubbles of gas. Copper, iron, and silver ore have been discovered; but the island is chiefly noted for its petroleum wells, the oil derived from which is of excellent quality, and is extensively used in the composition of paint, as it preserves wood from the ravages of insects. Timber is not abundant, but the gamboge tree and the wood-oil tree are found of a good size. Tobacco, cotton, sugar-cane, hemp, and indigo are grown, and the staple article is rice, which is of superior quality, and the chief article of export. The inhabitants of the island are mainly Mughas. Cheduba fell to the Burmese in the latter part of the last century. From them it was captured in 1824 by the British, whose possession of it was confirmed in 1826 by the treaty concluded with the Burmese at Yandaboo.

CHE-FOO, or YEN-TAI, as it is called by the natives, a seaport town of Northern China, on the southern coast of the Gulf of Pih-chih-li, in the province of Shan-tung near the mouth of the Yi-ho, and about 30 miles east of the city of Tang-chow-foo. Till recently it was quite a small place, and had only the rank of an unwallled village; but it was chosen as the port of Tang-chow opened to foreign trade in 1858 by the treaty of Tien-tsin, and it is now the residence of a Tau-tai, or intendant of a circuit, the centre of a gradually-increasing commerce, and the seat of a British consulate, a Chinese custom-house, and a considerable foreign settlement. The native town is yearly extending, and though most of the inhabitants are small shop-keepers and coolies of the lowest class, the houses are for the most part well and solidly built of stone. The foreign settlement occupies a position between the native town and the sea, which neither affords a convenient access for shipping nor allows space for any great extension of area. Its growth, however, has hitherto been steady and rapid. Various streets have been laid out, a large hotel erected for the reception of the visitors who resort to the place as a sanitarium in summer, and the religious wants of the community supplied by a Roman Catholic and a Protestant church. Though the harbour is deep and extensive, and possessed of excellent anchorage, large vessels have to be moored at a considerable distance from the shore. The foreign trade is mainly in the hands of the English and Americans, the Germans and the Siamese ranking next in importance. In 1872 there entered the port 233 British vessels, with a tonnage of 97,239 tons and cargoes valued at £144,887; while in the same year the ships of all other nationalities numbered 348, with a tonnage of 149,197 tons and a value of £177,168. The imports are mainly woollen and cotton goods, iron, and opium; and the exports include bean-cake, bean-oil, and peas, raw silk, and straw-braid manufactured by the peasants of Lai-chow-foo, walnuts from Tsing-chow-foo, a coarse kind of vermicelli, vegetables, and dried fruit. A certain amount of trade is carried on with the Russian settlements of Manchuria, in which the edible sea-weed gathered in the shallows of the coast are exchanged for piece goods, liqueurs, and sundries from China.

CHEESE, a solidified preparation from milk, the essential constituent of which is the proteinous or nitrogenous substance *casein*. All cheese contains in addition some proportion of fatty matter or butter, and in the more valuable varieties, the butter present is often greater in amount than the casein. Cheese being thus a compound substance of no definite chemical composition is found in commerce of many different varieties and qualities; and such qualities are generally recognized by the names of the localities in which they are manufactured. The principal distinctions arise from differences in the composition and

condition of the milk operated upon, from variations in the method of preparation and curing, and from the use of the milk of other animals besides the cow, as, for example, the goat and the ewe, from the milk of both of which cheese is manufactured on a commercial scale.

The quality and the composition of the milk operated on are of prime importance in cheese-making. Not only does this substance vary widely in richness and flavour owing to the breed, the nature of the food, and the state of the health of the animal yielding it, and many other circumstances; but in cheese-making the differences are still further increased, in some cases by adding cream to it, and in others by using it as skim-milk or milk deprived of a portion of its fat. Taking as a standard the ordinary sweet milk of cows, the following analyses (No. 1 given on the authority of Dr Parkes, and No. 2 by Dr Voelcker) may be taken to represent its average composition:—

Composition	No. 1	No. 2
Water	86.7	86.65
Butter	3.7	3.69
Casein	4.0	3.47
Milk Sugar	5.0	5.11
Mineral matter	0.6	.78

The object of the cheese-maker is to obtain in a solid form as large a proportion as possible of the casein and butter contained in the milk dealt with. The poverty in these constituents of the whey or liquid matter separated in the process of making cheese is therefore, to some extent, a measure of the success of the operation. The average composition of the whey drained off may be thus stated:—

Water	92.95
Butter24
Casein81
Milk Sugar and Lactic Acid	5.27
Mineral matter73

Milk, as is well known, if allowed to stand for some time, becomes thick, and is then separable into two portions—a solid white curd, and a greenish liquid whey. Such a coagulation and separation is essential in the making of cheese; but only to a small extent, in Holland and some other localities, is the natural acid coagulation taken advantage of. It has been assumed that the solid constituents of milk are held in solution by an alkaline substance, and that coagulation is the result of the neutralization of the alkali by the development within the fluid of lactic acid, as in the case of sour milk, or by the addition of an acid substance as is sometimes the practice; but this theory does not satisfactorily account for all the phenomena of coagulation. Acid substances, however, do readily curdle cheese, and hydrochloric acid, tartaric acid, vinegar, and cream of tartar have all been employed to produce coagulation for cheese-making. The curdling is also, in practice, produced by the action of such substances as the juice of figs, and decoctions of thistle tops, artichoke flowers, the butter-wort, and other plants. But the substance used uniformly in Great Britain, and in all great cheese-producing districts, is rennet, a preparation of the fourth or digesting stomach of the suckling calf. Rennet is prepared by cutting up the membrane in strips, salting, smoking, and sometimes treating it with spices and aromatics. The influence of rennet is due to the fact of its exciting a kind of fermentative action; but that it thereby changes the sugar of milk (lactin) into lactic acid, and so coagulates the casein, has been denied by Dr Voelcker, who holds its action to be "*sui generis*, and as yet only known by its effects."

In the practice of cheese-making it is found necessary, in order to hasten the coagulating action of rennet, and to produce a curd of sufficient hardness, to heat the milk to a temperature which varies from 72° to 85° or 90° Fabr. The lower temperature, it is found, yields a soft cheese, retaining

much whey and ripening soon; while the increased heat produces a firm curd and a solid slow-ripening cheese. After due coagulation the curd is broken, and by a variety of manipulative processes as much as possible of the whey is drained away, and the curd is reduced to comparatively dry crumbly fragments. At this stage, sometimes, but not frequently, the curd is salted; it is then collected into a clean cheese-cloth, placed in a cheese vat of the form and size of the cheese to be made, and submitted to pressure in the cheese press. While in the press it is frequently turned, a good deal of whey meantime continuing to exude; and it is found that the amount of pressure has much influence on the solidity and rate of ripening of the cheese. As soon as a sufficient skin has formed on the cheese to preserve its shape, it is removed from the press and salted by repeated rubbings of salt over its surface. The cheese is then put aside in a clean, cool, airy situation for ripening, a process which takes a variable period according to the quality of the cheese, its method of preparation, and other circumstances.

The ripening of cheese is the result of a slow process of decay caused by a spontaneous fermentative action. In hard, solid, poor cheeses it acts very slowly, while in those which contain butter in large proportions its action is very energetic, and they cannot be preserved for any considerable period. Cheese when newly made has an acid reaction, but by degrees from without inwards the acid reaction becomes less apparent, and the cheese ripens. A portion of the casein suffers decomposition, evolving ammonia and ammoniacal bases which neutralize the acid of the cheese. In a similar way the fat is partly decomposed, and the resulting fatty acids also combine with the ammonia evolved by the casein. When this action is allowed to proceed too far the cheese becomes alkaline, putrefactive decay ensues, free ammonia is evolved, an offensive odour is produced, and sometimes even poisonous compounds are formed. A satisfactory indication of ripening found in Stilton and other rich cheeses is the appearance of a green mould, streaked throughout the mass, produced by the fungus *Aspergillus glaucus*. A red mould also develops from *Sporendonema Casei*, and when the ripening becomes advanced the cheese-mite, *Acarus domesticus*, is produced with great rapidity in inconceivable numbers.

In England the milk of cows only is used in the manufacture of cheese. Excluding the so-called cream cheeses—a preparation of a soft buttery consistence made from cream gently pressed, which must be used new and fresh,—British cheese may be divided into three classes:—1st, that made with whole milk plus cream; 2d, that made with whole milk; and 3d, that made with milk minus cream, or skim-milk. Stilton and double Gloucester belong to the first class, being made of morning milk to which the cream of the previous evening's milking is added. Whole milk cheeses are represented by single Gloucester, Cheshire, Cheddar, and Dunlop; and the ordinary country cheese used by the labouring classes represents the third class. It must, however, be understood that all gradations in richness are met with in cheese, as seen by the table below, and that quality depends on other circumstances besides proportion of butter. Of foreign cheese imported into Great Britain, the most important in point of quantity and value is American; and since the introduction of the factory system of cheese-making in the United States, this has greatly improved in quality and become an important and extensive article of commerce. A large quantity of cheese, both fat and poor, is also made and exported from Holland. Parmesan cheese and Gruyère cheese, which are highly relished on account of their flavour, are skim-milk products, the former being coloured and artificially flavoured with saffron. The celebrated French Roquefort cheese is made from ewe's

milk, and matured in the caves of Roquefort, where a uniform low temperature is found throughout the year. The accompanying table, compiled from various sources, gives the average composition of the principal kinds of cheese at present known in commerce:—

	Water.	Casein.	Fat.	Milk-Sugar, &c.	Acid and Salts.
Stilton	20.27	33.45	43.98	...	2.30
Cheshire	32.59	26.06	32.51	4.53	4.31
Cheddar	30.32	28.18	35.53	1.66	4.31
Double Gloucester	33.41	27.75	32.69	2.23	3.92
Single Gloucester	36.50	25.75	28.75	4.68	4.32
Wiltshire	39.22	34.22	19.26	2.28	5.02
Dunlop	38.46	25.87	31.86	...	8.81
Ordinary Skim-milk	39.43	30.37	27.08	0.22	2.53
American	27.29	25.87	35.41	6.21	5.25
Dutch (Gouda)	36.10	29.43	27.51	6.94	...
Camembert	51.94	18.90	21.05	4.40	4.71
Parmesan	27.56	44.08	15.95	6.60	5.72
Gruyère	40.00	31.50	24.6	1.5	3.66
Brie	45.25	18.48	25.73	4.94	5.61
Roquefort	34.55	26.52	30.14	3.72	5.67
Neufchâtel (Cream Cheese)	36.58	8.00	40.71	15.80	0.51

As an article of food cheese is used in a double capacity. Rich cheese in an advanced stage of ripeness is eaten in small quantities partly on account of its piquancy, and partly also as a digestive stimulant. Skim-milk cheese, and all the varieties poor in fat, again, are valuable articles of food on account of their high percentage of nitrogenous matter, and the cheaper qualities are, on this account, extensively consumed among the classes by whom other animal food is not usually obtainable. As an article of ordinary diet, cheese labours under the disadvantage of being hard of digestion; and especially when it is toasted, as is frequently the practice, it really is, as has been observed, 'about as digestible as leather.' According to Dr Frankland's experiments, the maximum amount of force produced by the complete oxidation of 1 lb of Cheshire cheese within the human body is 2704 foot-tons.

The imports of cheese into Great Britain during the year 1875 amounted to 1,626,413 cwt., of an estimated value of £4,705,229; of this quantity about one-half was imported from the United States and one-fourth came from Holland. Of course the imports only represent a small proportion of the total quantity consumed.

CHEETAH, or HUNTING LEOPARD (*Gueparda jubata*), a Carnivorous Mammal belonging to the family *Felidae*, but exhibiting in form and habits such a mixture of feline and canine characteristics as have led naturalists to regard it as a transition form between the cat and dog groups. Unlike the typical *Felidae*, its head is short and round, its legs elongate and slender, and the flesh tooth of the upper jaw thin and longitudinally compressed. Its claws, being only partially retractile, get blunted by exposure to the surface of the ground, and so are less adapted to the purely feline mode of capturing prey. The cheetah attains a length of 3 to 4 feet, is of a pale fawn colour, marked with numerous spots of a deep black on the upper surface and sides, and is nearly white beneath. The fur is somewhat crisp, altogether lacking the sleekness which characterizes the fur of the typical cats. Its tail is long and somewhat bushy at the extremity. In confinement it soon becomes fond of those who are kind to it, and gives evidence of its attachment in an open, dog-like manner. According to Mr Bennet (*Tower Menageries*) "the character of the cheetah seems to be entirely free from that sly and suspicious feeling of mistrust which is so strikingly visible in the manner and actions of all the cats, and which renders them so little susceptible of real or lasting attachment;" and it is the opinion of the same writer that the cheetah

might be thoroughly domesticated and "rendered nearly as familiar and faithful as the dog himself." The cheetah is found throughout Africa and Southern Asia, and has been employed for centuries in India and Persia in hunting antelopes and other ruminant game. According to Sir W. Jones, this mode of hunting originated with Hushing, king of Persia, 865 B.C., and afterwards became so popular that certain of the Mongol emperors were in the habit of being accompanied in their sporting expeditions by a thousand hunting leopards. In prosecuting this sport at the present day the cheetah is conveyed to the field in a low car without sides, hooded and chained like hunting-birds in Europe in the days of falconry. When a herd of deer or antelopes is seen, the car, which bears a close resemblance to the ordinary vehicles used by the peasants, is usually brought within 200 yards of the game before the latter takes alarm; the cheetah is then let loose and the hood removed from its eyes. No sooner does it see the herd, than dropping from the car on the side remote from its prey, it approaches stealthily, making use of whatever means of concealment the nature of the ground permits, until observed, when making a few gigantic bounds, it generally arrives in the midst of the herd and brings down its victim with a stroke of its paw. The sportsman then approaches, draws off a bowl of the ruminant's blood, and puts it before the cheetah, which is again hooded and led back to the car. Should it not succeed in reaching the herd in the first few bounds, it makes no further effort to pursue, but retires seemingly dispirited to the car. In Africa the cheetah is only valued for its skin, which is worn by chiefs and other people of rank. It forms an article of export from Senegal.

CHEKE, SIR JOHN (1514–1557), was born of good family at Cambridge, and was educated at St John's College. His learning gained him the position of king's scholar, and in 1540 he was chosen to fill the chair of Greek then instituted by Henry VIII. Together with Sir Thomas Smith he has the honour of being one of the first who revived the knowledge of that language in England. He specially interested himself in its pronunciation; and he finally carried his point, through his popularity with the students, notwithstanding the strenuous opposition of the chancellor, Bishop Gardiner. Among those whom he taught were William Cecil and Roger Ascham, the latter of whom, in his *Schoolmaster*, gave him the highest praise both for scholarship and character. About 1544 he was appointed tutor to Prince Edward, and on the accession of his pupil to the throne he received several considerable grants, and, among other honours, rose to the position of secretary of state. Unfortunately for himself he followed the duke of Northumberland, and acted as secretary to Lady Jane Grey during her nine days' nominal reign. In consequence Mary threw him into the Tower, and confiscated his wealth. In September 1554 he obtained his liberty, with leave to travel abroad. He visited Italy, gave lectures on Greek at Padua, and afterwards was forced to support himself by teaching that language at Strasburg. In 1556 he was lured to Brussels by a message that his wife was in that town, and, on his way thither, was seized by order of Philip of Spain, and again brought to the Tower. He was immediately visited by two Catholic priests, who failed to convert him till he was informed that he must recant or be burned. Upon this he yielded, and made two public recantations. He did not long survive his disgrace, and in September 1557 he died in London. Perhaps the most interesting of Cheke's works is the *Hurt of Sedition* (1549), which gives advice to the people who had risen in rebellion under Ket. To seek equality, he argues, is to make all poor; and, besides, "riches and inheritance be God's providence, and given to whom of His wisdom He thinketh

good." He also wrote Latin translations of some of St Chrysostom's homilies; *De Obitu Martini Bucerii* (1551); *De Pronunciatione Græcæ Linguae*, 1555; *De Superstitione*, presented to King Henry VIII.; translation of Leo *De Apparatu Bellico*; *Carmen Heroicum, aut Epitaphium in Antonium Deneium*. See Life by Strype.

CHELMSFORD, the county-town of Essex, in England, 29 miles N.N.E. of London, with which it is connected by the Great Eastern Railway. It is situated in a valley on the Chelmer, near the confluence of the Cann, and has communication by the river with Maldon and the sea, 11 miles to the east. The Cann is crossed by two bridges, one of stone and the other of cast-iron; and there is also a bridge over each of the two branches into which the Chelmer is divided at this part of its course. In the neighbourhood of the island enclosed by this bifurcation are the works of the gas company, and the wharves for the barges on the river. Besides the parish church of St Mary, an ancient and elegant edifice, rebuilt in 1428 and again in 1800, the town has seven churches and chapels belonging to different denominations, a grammar school founded by Edward VI., an endowed charity school, a mechanics' institute, a museum, and a library. It is the seat of the county assizes and quarter sessions, and has an elegant and commodious shire hall. Its corn and cattle markets are among the largest in the county; for the former a fine exchange was provided in 1856 at a cost of £10,000, and a similar sum is being expended on an enclosure for the latter. In the centre of the square in which the corn-exchange is situated there stands a bronze statue, by Bailey, of Lord Chief-Justice Tindal, who was a native of the parish. There are corn mills, tanneries, and a brewery in the town; but most of the inhabitants are engaged in agriculture or the trades immediately connected with it. About a mile to the north is situated the county jail at Springfield Hill, and at a distance of two miles to the south is the racecourse, with a grand stand erected in 1863. The town, not being a corporation, is under the government of a local board, and within the limits of that jurisdiction it had 9318 inhabitants in 1872.

Chelmsford lies but a short distance from the site of the Roman colony of *Cæsaromagus*, usually identified with Writtle. At the time of the Conquest the manor was held by the bishops of London; and in the reign of Henry I. the town was indebted for its bridge over the Cann to Bishop Maurice. After this improvement it rapidly increased in prosperity, and in the reign of Edward III. it sent four representatives to the council at Westminster. Of the Dominican convent founded in the town at an early period there are no remains; but a chronicle composed by friar Langford is still extant.

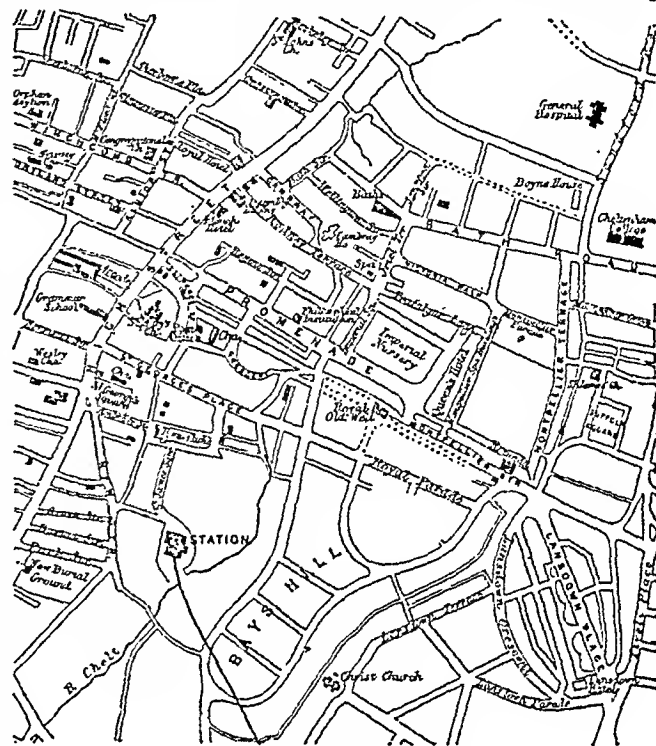

CHELSEA, formerly a village about two miles west of London, on the left bank of the Thames, but now an integral part of the great metropolis. It gives its name to a parish and a parliamentary borough, the former with 71,089 inhabitants, and the latter, which includes Fulham, Hammersmith, Kensington, and part of Willesden, with 258,050, at the census of 1871. It is connected with the district of Battersea on the other side of the river by three bridges, known respectively as Battersea, Albert, and Chelsea suspension bridges. Like many of the suburban villages of London, it has an interesting history of its own. In 785 it is mentioned by the name of *Cealscythe* as the seat of an ecclesiastical synod; and in *Domesday Book* it appears as *Cercebode* or *Chelched*. The name was still written *Chelchith* in the time of Sir Thomas More, who had a house in the village, but it began to assume the form of *Chelsey* in the 16th century. The manor was bestowed by Henry VIII. on Catharine Parr,

and it afterwards passed successively into the possession of the duke of Northumberland, Lord Cheyne, and Sir Hans Sloane. It was at Chelsea that Sir John Danvers introduced the Italian style of gardening, which was so greatly admired by Bacon and soon after became prevalent in England; and here in our own day were the gardens of the English botanist William Curtis, arranged according to the Linnean system. During the 18th century the village was the residence of many of the most famous men of the period. Atterbury, Swift, and Arbuthnot lived in Church-lane; Guy, Smollett, and Steele were for a time inmates of Monmouth House; and Count Zinzendorf established a Moravian society at Lindsay House. Sir Robert Walpole's residence was extant till 1810; and till 1824 the bishops of Winchester had a palace at the end of Cheyne Walk, a fine promenade extending along the river and now fronted by part of the Thames embankment, which has greatly improved its appearance. The house and grounds of the earl of Ranelagh were a favourite resort from 1742 till 1803; and Crenorne, which was built by the earl of Huntingdon, father of Steele's "Aspasia," is still a place of popular amusement. The old church and churchyard contain the tombs of Sir Thomas More, Sir Hans Sloane, George Herbert's mother, Thomas Shadwell, Woodfall the printer of Junius, and other persons of celebrity. Of greater importance than any of the buildings already mentioned is the great Chelsea Hospital for invalid soldiers, built by Sir Christopher Wren (1682-1690), on the site of King James's College; and to the north of the hospital is the Royal Military Asylum, founded by Frederick Duke of York, for the education of children connected with the army. For further details see the article LONDON.

CHELSEA, a city of the United States, in Suffolk county, Massachusetts, forming part of the suburbs of Boston. It is situated on the north bank of the Mystic River, which separates it from Charlestown, while Chelsea creek lies between it and East Boston. It communicates both with Charlestown and with East Boston by bridges. (See plan, vol. iv. p. 731). Its public buildings comprise the city hall, Winnisimmet hall, the naval hospital, the marine hospital, an academy of music, a free public library opened in 1870, a high school, a national bank, and about a dozen churches; and among its industrial establishments are several foundries, brick-works, worsted factories, soapworks, and oilworks, a manufactory of washing machines, a brewery, and a salt-refinery. It is supplied with water from the works in Charlestown, which are fed by the Mystic River. In 1871 there were 3092 houses in the city, and in 1874 the population amounted to 20,695, showing an increase since 1830 of 19,925. The first settlement dates from 1630, and in the following year Winnisimmet ferry was established. Till 1738 the place itself was known as Winnisimmet, and was regarded as part of Boston, but in that year it was organized as a separate town, for the convenience of its inhabitants, who found it difficult to attend the municipal meetings of the city. In 1857 it obtained a city-charter of its own.

CHELTENHAM, a parliamentary and municipal borough of England, in Gloucestershire, situated about 88 miles N.W. from London, in a valley watered by the Chelt, and sheltered on the E. and N.E. by the Cotswold Hills. Its streets and buildings are spacious and elegant, and its spas and promenades are reckoned among the finest in England. The "Promenade" *par excellence*, indeed, which extends for more than a quarter of a mile, and is lined with trees, will be a comparison with any in Europe. Besides the parish church of St Mary's, which probably dates from the 14th century, there are ten Episcopalian churches and numerous places of worship; several of them are beautiful specimens of modern architecture, and the Roman Catholic

church of Saint Gregory is especially admired. Among the educational institutions the most important are the well known Cheltenham College, which dates from 1842, and numbers upwards of 600 pupils; a foundation grammar school, originally established in 1574 by Richard Pates of Gloucester; a Church of England college for the training

Cheltenham (Central part).

of teachers for national and parochial schools; and the Ladies' College at Cambray House opened in 1854. Of the charitable institutions may be mentioned the General Hospital and Dispensary, which is supported by donations and subscriptions, and the Female Orphan Asylum, which owes its existence to Queen Charlotte. There are no manufacturing establishments of any importance; and the prosperity of the town, which has the reputation of being one of the healthiest, cleanest, cheapest, and best regulated places in the kingdom, is mainly due to its being a fashionable and educational resort. The mineral springs are four in number—the Old Wells, Montpellier, Cambray, and Pittville; and with the exception of Cambray, which is chalybeate, they all furnish a saline water. The Pittville spring is the mildest and most attractive, and it also possesses the best pump-room in the town,—a handsome building, surrounded by an Ionic colonnade, which was erected in 1825 by Joseph Pitt, at a cost of £20,000.

Cheltenham probably existed at a very early period, and Roman remains have been discovered on its site. The manor is described in *Domesday-Book* as *terra regis*, or king's land, and it possessed important privileges granted by several charters. In the reign of Queen Elizabeth the town was relieved from the burden of sending two members to Parliament. It rose rapidly into importance at the commencement of the eighteenth century through the discovery of its mineral waters, which were visited in 1788 by George III., and soon after attracted general attention. In 1804 it consisted of only one street, and contained 710 houses and 3076 inhabitants; whereas at the census of 1871 the parish, which has an area of 4203 statute acres, contained 7825 inhabited houses, and had a population of 41,924. The Parliamentary borough, which was extended by an Act of 31 and 32 Viet. to an area of 4451 acres, and contains part of the parish of Leckhampton, had in the same year 3321 inhabited houses and a population of 44,519 persons, of whom 18,370 were males, and 26,149 females. It returns one member to Parliament, and is the seat of a County Court, a centre under the Bankruptcy and Judicature Acts, and the depot of the county police.

CHEMISTRY

HISTORICAL INTRODUCTION.—The acquaintance of the ancients with the modes of extracting several of the metals from their ores, and also with the arts of dyeing, tanning, and glassmaking, and their recognition of various kinds of salts, earths, and inflammable substances show that they must have been possessed of a knowledge of a considerable number of chemical facts; but that this knowledge was to any extent gained by experimental research rather than by mere accident, or that when acquired it was applied to the classification of chemical phenomena, or to the establishment of any theory explanatory of them, there is no evidence to show. Until comparatively recent times the principles of metaphysical philosophy were not recognized as distinct from those of chemistry; men of learning gave themselves up to speculation upon the obvious physical characteristics of matter, whilst they neglected the indirect observation of their intrinsic and specific properties; analogies were a sufficient basis for the classification of bodies, and a consideration of their external peculiarities—"a decomposition of bodies," to use the words of Whewell, "into adjectives, not into substantives"—stood in the place of analysis. Thus we find that the qualities of the "elements" of the school of Aristotle are all physical, they are dry or humid, warm or cold, light or heavy; the idea of substances distinguished by special chemical properties was as yet no less foreign to men's minds than a knowledge of their ultimate composition.

Ideas similar to those of Aristotle concerning the elementary constitution of the universe were early prevalent in the East, whence they appear to have found their way into Europe. The elements, according to the Hindus, were earth, air, fire, water, and ether, and in the fourth book of "Chow," forming part of the Chinese historical records known as the *Shoo King*, there is a document supposed to date from 2000 B.C., in which is given an account of the five elements, namely, earth, fire, water, metal, and wood. Of what precisely was meant by an "element" in the language of the ancient philosophers and early chemists it is difficult to get any definite idea; the term could hardly, in fact, be used otherwise than in a vague sense before the exact processes of chemical analysis had shown that the properties of matter vary according to the presence or absence within it of definite quantities of certain substances, distinct in properties from one another, and unresolvable into other substances.

To the doctrine of a plurality of elements, as opposed to the systems of Thales and Heraclitus, may be ascribed the origin of the conception that by the analysis and synthesis of bodies the various kinds of matter with all their diversity of physical features might be produced, a conception that took practical shape in the processes of alchemy, which, as Liebig has remarked, "was never at any time different from chemistry." During the alchemical period a knowledge of the properties of bodies was acquired; afterwards chemistry showed the relations, connections, and limits of these properties. The first mention of *chemistry* (χημεία) is found in the dictionary of Suidas, who flourished in the 11th century; he defines it as "the preparation of silver and gold," and relates that Diocletian, lest the Egyptians should become rich and capable of resisting the Roman power, caused their books on chemistry to be burnt. He further asserts that the art was known as early as the period of the Argonautic expedition, the golden fleece being a treatise written on skins (δέρμασι) concerning the making of gold. The belief in the art of making gold and

silver, held by the Greeks from the 5th to the 15th century, was by them communicated to the Arabs, possibly not long after the conquest of Egypt in 640; and from the 11th to the 15th century alchemy was diligently studied by the philosophers of Italy, France, Germany, and England.

That the claims of alchemy, notwithstanding repeated demonstrations of their futility, so long received the serious attention of mankind, is attributable to various causes. Not only did impostors find free scope in the credulity of an age of ignorance for the exercise of their arts; but men of talent and culture, relying on tradition, were led honestly to support the doctrine of the transmutation of metals. The existence of the philosopher's stone having once been accepted as an ascertained fact, it is not extraordinary that Isaacus Hollandus is able to indicate the method of its preparation from "adamite" or "virgin" earth, and its action when medicinally employed; that Roger Bacon, Raymond Lully, Basil Valentin, and John Price know the exact quantities of it to be used in transmutation; and that George Rippel, in the 15th century, has grounds for regarding its action as similar to that of a ferment. In the view of some alchemists, the ultimate principles of matter were Aristotle's four elements, the proximate constituents were sulphur and mercury, the father and mother of the metals; gold was supposed to have attained to the perfection of its nature by passing in succession through the forms of lead, brass, and silver; gold and silver were held to contain very pure red sulphur and white quicksilver, whereas in the other metals these materials were coarser and of a different colour. Geber, judging from an analogy instituted between the healthy human being and gold, the most perfect of the metals, regarded silver, mercury, copper, iron, lead, and tin in the light of lepers that required to be healed.

To the evidence of their imaginations the alchemists were able to add that of actual observation; the fact that many ores resembling metals were changed and decomposed by heat could not but offer support to theories formed at a time when the nature of chemical combination was not understood; and the apparent transition of many bodies into one another, as, for example, that of clouds into water, was not less wonderful to them than the transmutation of the lighter metals into gold.

It was in the 16th century that a new race of alchemists, or spagyrist, as they were termed, arose, who, abandoning the search for the philosopher's stone, began to direct their energies to the discovery of chemical remedies for the various diseases of the body. "The true use of chemistry," says Paracelsus (1493-1541) "is not to make gold, but to prepare medicines." Rejecting the teaching of Galen, he admitted three or four elements, the *star*, the *root*, the *element*, and the *sperm* or *true seed*, which were originally confounded together in the *chaos* or *ylidos*; these elements he asserted were composed of the three principles *sideric salt* and *sulphur* and *mercury*, the cause respectively of the qualities of fixity, combustibility, and fluidity and volatility. The theories of Paracelsus found many advocates, amongst whom may be mentioned Thurneysser (1531-1596), Bodenstein, Taxites, Dorn, Sennert, and Duchesne; and with some modifications they were maintained in the 17th century by Dr Willis (1621-1675), the celebrated English anatomist and iatro-chemist, and by Lefebvre and Lémery in France, according to whose system matter consisted of the active principles *mercury* or *spirit*, *sulphur* or *oil*, and *salt*, and the passive principles *water* or *phlegm* and *earth*.

Among the contemporaries but not the followers of Paracelsus, the German metallurgist Agricola (1494-1555) deserves mention; his great work, *De Re Metallica*, is the most valuable contribution to practical chemistry that appeared in the 16th century. Libavius also, who died in 1616, did much to forward chemical science at this period. From his writings, however, in which he puts forward the views both of Paracelsus and of Aristotle concerning the constitution of bodies, it does not appear that his notions of chemical combination were more definite than those of his predecessors.

J. B. Van Helmont (1577-1644), who, like Paracelsus, repudiated the doctrines of the Galenists, held opinions that in many respects were no advance upon those of the former. He looked upon water as the true principle of all existing things, inclusive of the three principles salt, sulphur, and mercury, which therefore were not elements; to air, however, he granted the rank of a true element. The *archæus*—something without form, and independent of the elements—he imagined to draw all bodies from water, to which its generating spirit was attracted by the odour of a ferment or *aura vitalis*. The vapour produced by the fermentation of water was, according to Van Helmont, a gas, and the same term was by him for the first time applied to carbon dioxide, which he termed *gas sylvestre*, and to other bodies resembling air.

To Francis de la Boë Sylvius (1614-1672), who studied with care the works of Van Helmont and of Descartes, is due the foundation of the intra-chemical sect among physicians. In his view the health of the human frame depends upon the relation of its fluids, which were acid and alkaline (*acidum* and *lieivum*), and these by union produced a neutral and milder substance; two kinds of diseases were distinguished, the result either of alkaline or of acid acidity. The new doctrine served to explain many chemical facts, and led to the establishment by Lémery and Macquer of a distinction between acid and alkaline or, as they were afterwards called, basic compounds. This recognition of this chemical difference in bodies and their consequent disposition to unite prepared the way for the conception of chemical attraction or affinity.

In the works of Glauber (1604-1668), alchemy, the preparation of chemical medicines, and the processes employed by him for that end are treated of. His *Miraculum Mundi* has for its subject the virtues of the *sal mirabile*, sulphate of sodium, or Glauber's salt, of which he was the discoverer; and in other of his works he describes various chlorides of the metals, the sulphates of iron and copper, and sulphuric, nitric, and hydrochloric acids, but with respect to their ultimate constitution he advances no theory; he variously states in his different works that mercury and salt are the principles of all metals, that salt is the origin of all things, and again that water and earth have produced all the minerals and metals.

The first to attempt to overthrow the doctrines of the iatro-chemists was Robert Boyle (1627-1691), who in 1661 published the first edition of *The Sceptical Chemist, or Chymico-Physical Doubts and Paradoxes touching the Experiments whereby vulgar Spagyrist are wont to endeavour to evince their Salt, Sulphur, and Mercury to be the true Principles of Things*, a treatise in which he shows the doubtful character of the doctrine of the threefold constitution of matter, and lays stress upon the influence of heat in the formation of new bodies, not necessarily pre-existent as such in the substances from which they are produced. If, as he tells us, he is somewhat too indulgent of suspicion against the hypotheses or arguments of other chemists, he is only acting in compliance with the advice of Aristotle, and bending a crooked stick the contrary way, to reduce it at length to straightness. Into the mouth of

"Thomistius" he puts the complaint that "Aristotle's hypothesis had not been called in question till in the last century Paracelsus and some few other sooty empiricks, . . . having their eyes darkened and their brains troubled with the smoke of their furnaces, began to rail at the Peripatetic doctrine, which they were too illiterate to understand, and to tell the credulous world that they could see the three ingredients in mixed bodies, which, to gain themselves the repute of inventors, they endeavoured to disguise by calling them—instead of earth, and fire, and vapour—salt, sulphur, and mercury, to which they gave the canting title of hypostatical principles." Boyle inclines to a belief in "but one universal matter of things, as it is known that the Aristotelians themselves acknowledge, who called it *materia prima*; . . . the portions of this matter seem to differ from one another in certain qualities or accidents, fewer or more." He thinks that elementary corpuscles are of various sizes, and of more sorts than three or four or five; and that the combination of two of these corpuscles may give rise to a new body as really one as either of the corpuscles before they were mingled or confounded, this concretion being endowed with distinct qualities, and no more by fire or any known way of analysis divisible into the corpuscles that had first concurred to make it, than either of them could by the same means be subdivided into other particles. He furthermore deduces from his arguments the corollary, "That it may as yet be doubted whether or no there be any determinate number of elements; or, if you please, whether or no all compound bodies do consist of the same number of elementary ingredients or material principles." In another work, *The Imperfections of the Chemical Doctrine of Qualities*, Boyle points out the arbitrary nature of Sylvius's classification of all substances as acids and alkalis, and the needlessness and unsatisfactory character of his hypotheses. Iatro-chemistry was opposed also by Couring (1606-1681), Sydenham (1624-1689), Pitcairne (1652-1713), and his pupil Boerhaave (1668-1738), the author of the excellent *Elementa Chemicæ*; and though vigorously supported by De Blegny, Borrichius, Viridot, Vionssens, and others, it gradually lost repute, and was finally overthrown by F. Hoffmann (1660-1742).

Of the labours of Kunkel (1630-1703) in the cause of chemistry it is impossible to give an account within the compass of the present sketch; but whilst the science was enriched by means of his numerous researches, amongst which may be mentioned those on phosphorus, it received no assistance from his theoretical views concerning the constitution of bodies; thus, for instance, he rejected the belief in the three principles of Paracelsus, yet maintained that all metals contained common quicksilver; and though their increase in weight by calcination was not, according to him, due to the absorption of ponderable fiery material, the explanation he offered of this phenomenon was even less satisfactory.

To Becher (1635-1682) and to Stahl (1660-1734) chemistry owes the introduction of the first consistent theory of the constitution of compounds and of chemical action. Becher held that the primary ingredients of matter were water and earth, and that from these were produced three earths—the fusible or stony, the fatty, and the fluid earths,—improperly called salt, sulphur, and mercury. Stahl, who developed the doctrines of Becher, enumerated four elements—water, acid, earth, and phlogiston. Becher had explained the calcination of metals on the supposition that they consisted of an earth and a something of which they became deprived on ignition; the burning of brimstone was, in like manner, thought to be its resolution into an acid and true sulphur, or that combustible part which was expelled by heat. It was this supposed combustible body to which the name phlogiston

(φλογίστον, combustible) was applied by Stahl—the *materia aut principium ignis non ipse ignis*. The phlogiston of Stahl answers in some measure to the souls and spirits assigned to metals and salts by the alchemists, or to what Geber called the “humidity,” and Cardan the “celestial heat” of metals. When by means of charcoal a metallic calx was reduced, or a compound containing sulphur was obtained from fused sodium sulphate, phlogiston was supposed to be absorbed from the charcoal, which with aemp black and other reducing agents came in time to be regarded as nearly pure phlogiston. Bodies that would not burn were thought to have already parted with their phlogiston. From a consideration of the insolubility of most combustible substances arose the idea that phlogiston was a dry and earthy body, capable of receiving a motion of great velocity—the *motus verticillaris*—manifested when ignition or flame was produced. John Rey had in 1630 remarked that metals grow heavier when calcined by the absorption of “thickened air,” but had given no general theory of combustion, or explanation why many substances become lighter or are lost sight of when heated. Boyle, too, had noticed the increase of weight caused by the calcination of metals, and had attributed it to the combination of the latter with heat particles; and Stabel and others were not slow to object that this fact negated the supposition that calcination consisted in a subtraction of phlogiston; the Stahlans, however, met the difficulty by declaring that substance to be the principle of levity or negative weight.

F. Hoffmann, who contributed greatly to the progress of analytical chemistry in Germany, held with Stahl that sulphur consisted of acid and phlogiston, and that combustible bodies contained something which might be described as phlogiston, but thought it possible that the calces of metals were formed, not by the subtraction of phlogiston, but by the combination of the metals with an acid material. Boerhaave, without directly attacking the phlogistic theory, casts doubts upon the assumption of the existence of a combustible principle and of earthy substances in the metals. The view of Homberg (1652–1715) was that the principle of combustibility in inflammable minerals and in vegetable substances was sulphur; and E. F. Geoffroy (1672–1731) regarded phlogiston as a sulphurous or oily principle. Amongst the most active supporters of the doctrines of Stahl were Neumann (1683–1737); J. H. Pott (1692–1777), distinguished for his researches on the behaviour of mineral substances at high temperatures; Marggraf (1709–1782); and Macquer (1718–1784), the discoverer of arsenic acid. Other celebrated chemists who flourished during the phlogistic period were Réaumur (1683–1757), Hellot (1685–1766), and Duhamel du Monceau (1700–1782), who first proved the nature of the base of common salt.

The phlogistic theory of Stahl, though incorrect, was of no small assistance towards a true understanding of chemical phenomena. It was based upon experimental data, the interpretation of which served for the correlation of facts of which but vague and enigmatic explanations had formerly been given. The supposed subtraction of phlogiston in the calcination of metals, though equivalent in reality to the addition of oxygen, was yet a loss of potential energy, by virtue of the combination of the metal with the gas; and the gain of phlogiston was an increase of potential energy, attendant on the removal of oxygen.

It was only in the latter part of the 18th century that the influence of the presence of air upon the formation of many chemical compounds was generally perceived, and that through the use of the balance the nature of gases began to be comprehended and such airy nothingness

became commonly regarded as an intimate and necessary constituent of various solid and fluid bodies. The phlogistic theory gave to its adherents so plausible and moreover so circumstantial an account of the modes of chemical action, that facts and observations which caused at a later time a complete revolution in the theory of chemistry, such, for instance, as regarded the existence and properties of oxygen, remained without explanation, and almost unheeded. Robert Hooke, so early as 1665, in his *Micrographia*, foreshadowed the discoveries of Priestley and his contemporaries, when he advanced the opinion that in common air there existed a substance like, if not the same as, that fixed in saltpetre, and which at an elevated temperature dissolved combustibles such as sulphurous bodies with a rapidity sufficient to occasion the motion of fire, and to create light; this solvent he considered to be far less for a given bulk of air than of saltpetre. The investigations of Mayow (1645–1679) are particularly interesting. In treatises published at Oxford in 1668 and 1674 oxygen is actually described by him under the name of *fire-air*, *aërial spirit*, and *nitre-air*; all acids are said to contain it, and it is necessary for combustion and respiration, processes which are therefore analogous; it is the nitre-air of the atmosphere that causes fermentation and the souring of wines, that produces sulphuric acid from sulphur, and effects the calcination of metals.

Early in the 18th century Newton in his *Opticks* indicated the nature and the modes of formation of gases. “Dense bodies,” he tells us, “by fermentation rarely into several sorts of air; and this air by fermentation, and sometimes without it, returns into dense bodies;” and further on he remarks that the particles shaken off from bodies by heat or fermentation, so soon as they are beyond the reach of the attraction of the body, recede from it, and also from one another with great strength, so as sometimes to take up above a million of times more space than they did before in the form of a dense body. This vast contraction and expansion seem to him unintelligible by feigning the particles of air to be spry and ramous, or rolled up like hoops, or by any other means than a repulsive power; the particles of fluids which do not cohere strongly are most easily rarefied into vapour; but those which are grosser, or cohere by a stronger attraction, are not separated without a stronger heat, or perhaps not without fermentation; being rarefied by fermentation they become true permanent air, those particles receding from one another with the greatest force, and being most difficultly brought together, which upon contact adhere most firmly.—(*Opticks*, bk. iii, qu. 30 and 31, 1730.)

In 1727 Dr Stephen Hales (1677–1761), who had for some years been engaged in investigations similar to those of Mayow, gave to the world in his *Statical Essays* the collective results of his observations. The atmosphere he describes in this work as a fine elastic fluid, with particles of very different natures floating in it, whereby it is fitted to be the breath of life of vegetables as well as of animals. The effect of respiration and of the burning of sulphur in air is to deprive it of its elasticity; and country air is cleaner and more elastic than that of towns. Elasticity, we read, is not an essential immutable property of air particles; “they are easily changed from an elastic to a fixed state by the strong attraction of the acid, sulphureous, and saline particles, which abound in the air. Whence it is reasonable to conclude that our atmosphere is a chaos, consisting not only of elastic, but also of unelastic air particles, which in great plenty float in it.”—(*Stat. Ess.*, vol. i. 4th ed., 1769.) Hales did not, however, attempt to determine the distinctive properties of the various gaseous constituents of the atmosphere, and of the substances on which he experimented; all are indiscriminately designated

"air." It is air that is generated by fermentation, and that contributes to the briskness of Pyrmont and other mineral waters; 108 cubic inches of air are procured from a cubic inch of iron filings and the same quantity of oil of vitriol; and 33 cubic inches of air are the result of distilling a cubic inch of dog's blood. Hales determined also the volume of air to be obtained by distilling certain quantities of amber, chalk, coal, grey pyrites, aqua-fortis, antimony, tobacco, and other materials, but apparently with no other end in view than the establishment of the fact that air is contained in a great number of substances. He had learned to interrogate, but not to cross-examine nature.

The first important step towards a knowledge of the specific properties of the various gaseous bodies was that made in the middle of the 18th century by Dr Black, who experimentally proved that the causticity acquired on ignition by mild magnesia and lime was attributable not to the entrance into them of ponderable caloric, but to the expulsion of a peculiar kind of air, which occurred fixed, or in a state of combination, in the unburnt or mild earths, and caused them to be heavier before than after exposure to heat. He found it possible, in fact, to impart to these substances a large amount of heat, which became latent, whilst at the same time their weight was lessened by the loss of "fixed air" (carbon dioxide). It was discovered by Black that alkalis in contact with quicklime became caustic by giving up their fixed air to the lime, which was thereby increased in weight and rendered mild. It was thus, by employing the balance as an experimental test of the composition of bodies, that Black laid the foundation of quantitative chemistry, and in so doing gave the first occasion to the strife that twenty years later began to rage between the followers of Stahl and the antiphlogistians.

Foremost in the number of those who after Black distinguished themselves as pneumatic chemists, was Dr J. Priestley (1733-1804). His first discovery, made in 1772, was nitric oxide gas, which he soon employed in the analysis of air. Boyle, more than a century before Priestley began his experiments, had stated in *The Sceptical Chemist*, that "without the addition of any extraneous body, quicksilver may by fire alone, and that in glass vessels, be deprived of its silver-like colour, and be turned into a red body; from this red body, without addition, likewise may be obtained a mercury bright and specular as it was before."—(*Boyle's Works*, ed. Birch, p. 352, Lond. 1744.) On the 1st of August, 1774, Priestley discovered that the red oxide of mercury evolved a gas when heated. This gas (oxygen) being superior even to the air as a supporter of combustion was regarded by him as *dephlogisticated air*; the incombustible part of the atmosphere he supposed to be saturated with phlogiston, on the assumption that a gas was so much the better adapted for supporting combustion as it contained within itself a smaller quantity of that body. Common air, by drawing phlogiston from burning substances, became, as he thought, phlogisticated air, and on that account had no longer any attraction for phlogiston, or, in other words, any power of supporting combustion. The phlogiston evolved in the burning of combustibles and in the calcination of metals was supposed to unite with the atmosphere or the dephlogisticated air contained therein, and that which was produced by the action on the atmosphere of the phlogiston lost by the metals was the cause of the increased weight of their calces. The opinion that the air given off during the solution of metals in acid was their combustible constituent had been advanced in 1700 by Lémery; and Priestley, guided apparently by the notion suggested by Cavendish's experiments, that to unite with acids metals must part with their phlogiston, considered inflammable air (hydrogen) either as identical with or at least very rich in that principle. In 1788, in order to explain the formation

of water from a mixture of inflammable and dephlogisticated air, he put forward the hypothesis that water entered into the composition of these and of fixed and other airs; inflammable air, he thought, might be the principle of alkalinity, dephlogisticated air, as Lavoisier had shown, being the principle of acidity. To the last Priestley was an advocate of the phlogistic philosophy, and though unquestionably one of the fathers of modern chemistry was always, to quote the words of Cuvier, "un père qui ne voulut jamais reconnaître sa fille." Besides nitric oxide and nitrogen, Priestley first made known sulphurous acid gas, gaseous ammonia and hydrochloric acid, and carbon monoxide; and he it was who, by showing that the condition of ammoniacal gas and of common air is altered by the transmission of electric sparks, led to Berthollet's analysis of ammonia, and Cavendish's discovery of the composition of nitric acid.

Henry Cavendish (1731-1810), who, like Priestley, was of the phlogistic school, contributed by his discoveries and carefully conducted investigations, especially as regards gases, scarcely less than that experimenter to the advance in chemical knowledge which before the beginning of the 19th century effected the subversion of the Stahlian philosophy. To him chemists are indebted for the invention of the pneumatic trough, and to him is due the first recognition of the importance of determining the specific gravities of the various gases. He established the radical difference between hydrogen and nitrogen, and discovered in 1781 that hydrogen and dephlogisticated air (oxygen), when exploded in a close vessel in proportions sufficient almost entirely to phlogisticate the burnt air, produced pure water; and that water was also formed when a mixture of common air and inflammable air was exploded, a reduction of one-fifth of the bulk of the former air being then observable. According to Cavendish, water consisted of phlogiston and dephlogisticated air; inflammable air, of phlogiston and water; the action of dephlogisticated upon inflammable air when exploded with it was to unite with its phlogiston to form water, and consequently to set free the water of the inflammable air; thus both airs became water.—(*Trans. Roy. Soc.*, 1784 and 1785.) Lavoisier had shown in 1770 the incorrectness of the notion prevalent among chemists that water by continued boiling and redistillation could be transformed into an earth. Cavendish's discovery deprived it of the rank of an element, to which, according to the vague Aristotelian doctrines of the time, it was entitled, and thus prepared the way for the acceptance of correct and definite views concerning the elementary bodies. Lavoisier, availing himself of the facts ascertained by Cavendish, taught that oxygen, the so-called dephlogisticated air, was an element, and that combined with it was imponderable caloric; inflammable air, or hydrogen, as he termed it, was another element, which had the power of disengaging from caloric a weight equal to its own of oxygen, with which it united to form water. The new doctrine did not, however, meet with very ready acceptance from the phlogistians. "It is inconceivable," writes one of them, "how water, which is absolutely incombustible, should have so combustible a body as inflammable gas is for one of its component parts; whereas, by admitting pure air in its whole substance to be one of the component parts of water, and the other to consist of the base only of inflammable gas, which being burnt by the passage of the electric spark through it, its phlogiston is converted into light and heat, the whole doctrine of the generation of water becomes plain and easy."—(*Hopson, Chemistry*, 1789.)

Among the most eminent of the contemporaries of Priestley and Cavendish that cherished a belief in the existence of phlogiston was the Swedish chemist Scheele (1742-1786). In experiments made to ascertain the

nature of heat and fire, he found that measured quantities of common air, when kept in contact with certain substances, *e.g.*, solution of potassium sulphide or moist iron-filings, contracted in volume, and became incapable of supporting combustion. As the specific gravity of the air had not augmented, the decrease of bulk, Scheele concluded, could not be due, as he had at first conjectured, to the absorption of phlogiston; the atmosphere must, therefore, consist of two distinct bodies. One of these, the residual air, he assumed to be incapable of combining with phlogiston; the other, having a strong attraction for that substance, had united with it, forming heat, which had penetrated through the walls of the vessel containing it—hence the diminution of the original volume of air. Heat, Scheele considered, was decomposed by means of bodies which had a strong attraction for its phlogiston, such as the calces of gold, silver, and mercury, and oil of vitriol mixed with black manganese ore, and consequently the other constituent of heat, empyreal or fire-air (oxygen), became isolated. Heat could be synthesized, for it was produced by the union of the phlogiston of coals with fire-air. Light, like heat, was a compound of fire-air and phlogiston, but was richer in the latter constituent, to the varying proportions of which it owed its differences of colour. Subsequently, when it became impossible for Scheele to ignore the consideration of the increase observable in many substances after burning or calcination, he so far modified his views as to regard fire-air as a compound containing, with a very little phlogiston, a saline principle (*principium salinum*) and water, which last gave to fire-air the greater part of its weight. When fire-air formed heat by combining with phlogiston, it gave up its water to the materials it dephlogisticated, and thus it was that they were rendered heavier by ignition. Such, in brief, were the theoretical conceptions of Scheele; it is upon his work as a practical chemist that his fame must rest. Tartaric acid was isolated by him in 1769, and he made the discovery in 1774 of baryta and of dephlogisticated muriatic acid (chlorine), and in 1779 of glycerine, the properties of which he pointed out in 1784; in 1781 he demonstrated the nature of hydrofluoric acid, first obtained by him in 1771, and prepared tungstic acid, before unknown; and between the years 1776 and 1786 he discovered benzoic, molybdic, lactic, mucic, oxalic, malic, and gallic acids, and made important observations on the compounds of arsenious acid.

The advance made during the last part of the 18th century in analytical chemistry is attributable in great measure to the labours of Torbern Bergman of Upsala (1735-1784), who devised systematic methods of examining compounds by the wet way, and by means of the blow-pipe, and first rendered it possible to analyze minerals insoluble in acids by fusing them with an alkali or alkaline carbonate. In 1718 E. F. Geoffroy had published tables in which he exhibited the reciprocal chemical affinities of various substances, and these tables had been improved upon by Gellert in his *Metallurgic Chemistry*, 1751, and by Linbourn, 1761. Bergman, in 1775, gave in a dissertation on *elective attractions*, as he named affinity, an arrangement in 59 columns of all the chemical substances known at the time, in which was shown the order of their decomposition when in solution, and when exposed to a strong heat. The nature of the compounds formed by the mixture of reagents depended, in Bergman's estimation, on the sum of their attractions. Bergman contributed also in some measure to the determination of the constitution of neutral salts—a subject treated of by Homberg in 1699, and, after Bergman and Kirwan, investigated by Wenzel in his *Vorlesungen über die chemische Verwandtschaft der Körper*, published in 1777. From Wenzel's observations

the idea of equivalency took its rise. He showed that the products of the mutual decomposition of two neutral salts were themselves neutral, or, in other words, that the same weight of base satisfies definite quantities of two different acids. Thus, according to his experiments, 123 parts of lime and 222 of potash must be considered equivalent to each other, being both competent to neutralize 181.5 parts of sulphuric, or 240 parts of nitric acid.

In England, ten years previously to the publication of Wenzel's treatise, Cavendish described certain quantities of fixed alkali and marble as "equivalent;" and in 1788 he stated that a quantity of oil of vitriol sufficient to produce 100 parts of plumbum ponderosum with sugar of lead would dissolve 33 of marble, since he found by experiment that so much oil of vitriol would saturate as much fixed alkali as a quantity of nitrous acid sufficient to dissolve 33 of marble.—(*Phil. Trans.*, 1767, p. 102; 1788, p. 178.)

In 1792, J. B. Richter (1762-1807) published a work on *Stöchiometrie*, or the Art of Measuring Chemical Elements, in which he gave in two series of tables the weights of different bodies which neutralized 1000 parts of various acids, and the weights of acids that similarly corresponded to 1000 parts in the case of the bases, and pointed out the proportionality that existed between the weights of the bases, as also of the acids, in each series. There was, he remarked, a constant ratio between the quantity of an acid and the quantity of oxygen in the weights of the bases needed for its complete saturation,—a fact afterwards restated by Berzelius, who showed that a simple and uniform relation was observable between the amounts of oxygen in the acid and basic portions of salts of the same class.

Although neither the science of chemistry nor yet a change in its objects can be said to have originated with Lavoisier (1743-1794), the means he introduced of attaining those objects, the ideas he put forth concerning the constitution of bodies, and the explanations he gave of various phenomena were new, and gave to the science in the twenty years preceding his death a completely altered aspect. The mine of chemistry had yielded rich returns long before Lavoisier came to labour in it; he availed himself of the old workings and, extending them, opened the main lode. "He discovered," says Liebig, "no new body, no new property, no natural phenomenon previously unknown; but all the facts established by him were the necessary consequences of the labours of those who preceded him. His merit, his immortal glory consisted in this—that he infused into the body of the science a new spirit; but all the members of that body were already in existence, and rightly joined together."—(*Letters on Chemistry*, ii.) In the first of his papers, in 1765, Lavoisier indicates no doubt of the existence of phlogiston. In 1775 he still spoke of it, but in the following year he expressed his conviction that, for the elucidation of certain phenomena, one must ascribe to phlogiston other qualities than those assigned to it by Stahl. It was in 1775 that he presented to the French Academy a memoir *On the Nature of the Principle which combines with the Metals during their Calcination, and which augments their Weight*, in which he describes the formation of fixed air from charcoal in the reduction of calces, and the preparation and properties of oxygen; but he makes no allusion to the fact that Priestley had in November of the foregoing year made him acquainted with that gas, or to the observations of Bayen in the *Journal de Physique*, February and April 1774, to the effect that the change of a metal into a calx is attributable to the fixation of an aerial fluid, and that the red oxide of mercury is reduced by heat without the addition of anything, and loses in weight by reduction.

In 1776 Lavoisier, by experiments with phosphorus and sulphur, confirmed results already arrived at by him—that the atmosphere contained two gases, azote or nitrogen, and a highly respirable air, the absorption of which by burning substances accounts for their increase in weight. In 1777 he combated the assertion of Priestley that air is rendered irrespirable by becoming loaded with phlogiston, and showed that air in which candles were burnt furnished about two-fifths of its volume of fixed air, and that pure or dephlogisticated air under the same conditions became almost completely transformed into that gas. In a paper received by the Academy in 1778 Lavoisier broached his theory that the dephlogisticated air of Priestley was the universal acidifying or *oxygenizing* principle, which by combination with charcoal, sulphur, nitrogen, and phosphorus formed carbonic, vitriolic, nitric, and phosphoric acids, and with metals, calces; all the phenomena of combustion, Lavoisier contended, were explicable without the supposition of the existence of phlogiston, of which there was no evidence. In 1783, when he had determined to discover by carefully conducted experiments the nature of the product of the combustion of hydrogen, Lavoisier learned that Cavendish had ascertained that body to be water. He therefore repeated Cavendish's experiments, and with the aid of Meusnier proved that water contains hydrogen, by passing steam through a red-hot porcelain tube containing iron wire. Lavoisier had long been unable to hold the doctrine that hydrogen was the phlogiston of metals, seeing that the calces were actually heavier than the metals supposed to contain them, and that the hydrogen supposed to be evolved by the metals, though light, certainly had weight. Lavoisier now explained the production of hydrogen during the solution of metals in acids on the assumption that water was decomposed, its oxygen uniting with the metals, whilst its hydrogen escaped. In the case, however, of nitric acid, oxygen was supposed to be supplied by the acid. The effect of Lavoisier's reasonings upon his contemporaries is illustrated by Priestley's remark (*Phil. Trans.*, 1788, p. 155) that, "the doctrine of the decomposition of water being set aside, that of *phlogiston* (which in consequence of the late experiments on water has been almost universally abandoned) will much better stand its ground." But the fate of the Stahlian philosophy was sealed; and in 1792 Klaproth and the Berlin Academy gave in their adhesion to the new doctrines. Gren and Wiegleb in Germany, Delametherie in France, and Kirwan in England endeavoured but in vain, to support the phlogistic theory; and ere long Lavoisier's innovations could be regarded not simply as the anti-phlogistic, but as the universally accepted system of chemistry. "It was the glory of Lavoisier," wrote Davy in 1814, "to lay the foundation of a sound logic in chemistry by showing that the existence of this principle (phlogiston), or of other principles, should not be assumed where they could not be detected." In 1789 was published Lavoisier's *Traité élémentaire de Chimie*, in which the new chemical doctrines were set forth with remarkable clearness and ability. A list of 33 "simple substances" is given in the 2d part of the 1st vol. of this work, wherein light and caloric are included with oxygen, azote, and hydrogen as elements of bodies; but as to whether light was a modification of caloric, or caloric a modification of light, it was impossible, Lavoisier considered, to decide (*Traité élément.*, tom. 1. part ii. chap. 1). Under the head of "oxidable or acidifiable substances" he placed sulphur, phosphorus, carbon, and the muriatic, fluoric, and boracic radicals; the "oxidable and acidifiable metals" are antimony, silver, arsenic, bismuth, cobalt, copper, tin, iron, manganese, mercury, molybdenum, nickel, gold, platinum, lead, tungsten, and zinc; and the "simple

earthy and salifiable substances" are lime, magnesia, baryta, alumina, and silica. Of metallic oxides, he says (*Traité élément.*, tom. i. part i. chap. vii.), "they ought not to be considered as completely saturated with oxygen, because their action on that principle is balanced by the force of attraction exercised upon it by caloric. Oxygen, then, in the calcination of metals, obeys really two forces—that exercised by the caloric and that exercised by the metal." Davy, who by his experiments on the effects of friction on ice did much to dispel the belief in the materiality of heat, but who regarded light as a body in a peculiar state of existence, and consisting of minute particles, held the view that light in *phosozxygen* (oxygen gas) was intimately combined with oxygen.—(*Works*, vol. ii. pp. 11–32.)

The following table will serve to show the progress that has been made in the knowledge of the elementary bodies from the time of the publication of Lavoisier's *Traité élémentaire*; the second and third columns give the authorities by whom and the dates when these bodies were either first isolated, or were recognized as simple substances:—

Uranium	Klaproth	1789	Strontium	Davy	1808
Titanium	Klaproth	1795	Chlorine	Davy	1810
Chromium	Vauquelin	1797	Fluorine	Ampère	1810
Tellurium	Klaproth	1793	Iodine	Courtois	1811
Tantalum	(Hatchett & Ekeburg)	1801	Lithium	Arfvedson	1817
Vanadium	(Del Rio and Sefström)	1801	Selenium	Berzelius	1817
Cerium	(Berzelius, Uti-inger, & Klaproth)	1803	Cadmium	(Hermann & Stromeyer)	1818
Palladium	Wollaston	1803	Silicon	Berzelius	1823
Iridium	Tennant	1804	Zirconium	Berzelius	1824
Osmium	Tennant	1804	Bromine	Balard	1826
Rhodium	Wollaston	1804	Aluminium	Wöhler	1827
Potassium	Davy	1807	Glucinum		1828
Sodium	(Davy, and Berzelius & Pontin)	1808	Thorium	Berzelius	1828
Barium	(Davy, and Gay-Lussac & Thénard)	1808	Yttrium	Wöhler	1828
Boron	(Davy, and Berzelius & Pontin)	1808	Didymium	Mosander	1811
Calcium	(Davy, and Berzelius & Pontin)	1808	Lanthanum	Mosander	1843
Magnesium	Davy	1808	Erbium	Rose	1844
			Niobium	Claus	1844
			Cesium	(Kirchhoff & Bunsen)	1860
			Rubidium	Crookes and Lamy	1861
			Thallium	(Reich and Richter)	1862
			Indium	Boisbaudran	1875
			Gallium		

Lavoisier was assisted in the establishment of his system by Fourcroy (1755–1809), Monge (1746–1818), Guyton de Morveau (1737–1816), and Berthollet (1748–1822); Lavoisier's theory that oxygen was the principle of acidity was not, however, accepted by Berthollet. In 1803 appeared Berthollet's *Chemical Statics*, in which Bergman's conclusions with respect to the laws of the combination of acids and bases were disputed. Affinity, it was argued, could not be simply an attraction, for then no decomposition, but only an addition of constituents would take place when solutions of different compounds were mixed together; affinity might be regarded as an attraction between combining substances probably like that existing between the planetary bodies—an attraction dependent on mass, not on elective force, so that combination between the various kinds of matter could take place in all sorts of proportions. The complete removal of a constituent of a compound by means of a decomposing agent was attributed by Berthollet to its elasticity or insolubility in the free state. Thus, he considered that barium sulphate was precipitated by solution of potassium sulphate because it was insoluble in water, but that a triple compound was formed when solutions of the sulphates of sodium and potassium were mingled. The decomposition of ammonium carbonate by sulphuric acid he asserted to be due to the elasticity of the carbonic acid gas that escaped. Berthollet's hypotheses found an opponent in Proust (1755–1826), who had already written on the constancy of the relations by weight of the component parts of bodies, and had shown that tin and antimony unite with oxygen.

and iron with sulphur, in two definite proportions respectively. In a controversy with Berthollet that extended over some years he successfully demonstrated that all compounds are definite, and contain only certain determinate proportions of their constituents.

In August 1804, Dalton (1766–1844) communicated to Dr Thomson his theory of the atomic composition of bodies. Dalton's ideas had been vaguely foreshadowed by W. Higgins of Pembroke College, Oxford, in a publication entitled *A Comparative View of the Phlogistic and Antiphlogistic Theories*, where we read that—

“In volatile vitriolic acid a single ultimate particle of sulphur is intimately united only to a single particle of dephlogisticated air; and in perfect vitriolic acid every single particle of sulphur is united to two of dephlogisticated air, being the quantity necessary to saturation. As two cubic inches of light inflammable air require but one of dephlogisticated air to condense them, we must suppose that they contain equal number of divisions, and that the difference of their specific gravity depends chiefly on the size of their ultimate particles; or we must suppose that the ultimate particles of light inflammable air require two or three or more of dephlogisticated air to saturate them. If this latter were the case, we might produce water in an intermediate state, as well as the vitriolic or the nitrous acid, which appears to be impossible; for in whatever proportion we mix our acids, or under whatever circumstance we combine them, the result is invariably the same.”—(2d ed., 1791.)

The atomic theory first suggested itself to Dalton during his investigations on marsh-gas, or light carburetted hydrogen, and olefiant gas. He calculated that if the weight of carbon in each of these compounds were reckoned to be the same, then marsh-gas contained exactly twice the weight of hydrogen present in olefiant gas. He further observed that the quantity of oxygen in carbonic acid gas was twice as much as in carbonic oxide gas. These and similar facts he conceived might be explained by assuming the ultimate particles of matter to be incapable of further division, or, in other words, *atoms*, possessing definite weights, the ratios of which could be denoted by numbers, the weight of an atom of hydrogen being taken as unity. The combination of these atoms with one another would account then for the definite proportions in which the elements united. For clearness the atoms were represented by symbols, thus :—

	Relative Weights.
○ Oxygen	6·5
⊙ Hydrogen	1
● Carbon	5
Ⓛ Azote.....	5

Binary compounds with their weights were denoted thus :—

○ ⊙ Water.....	7·5
● ⊙ Olefiant gas	6
Ⓛ ⊙ Ammonia	6
○ ● Carbonic oxide	11·5

and ternary compounds in a similar manner :—

○ ● ⊙ Carbonic acid gas.....	18
● ⊙ ● Ether	11
⊙ ● ⊙ Carburetted hydrogen gas.....	7

The weight of the smallest particle of a compound was therefore, according to Dalton's theory, to be obtained by adding together the weights of its constituent atoms; the laws discovered by Wenzel and Richter were thus included within the law of atomic weights.

The new theory was promulgated in Dr Thomson's *System of Chemistry*, 3d edit., 1807. In the same year Thomson showed that the amount of oxalic acid required to form strontium binoxalate was twice as great as that in the case of the oxalate, supposing the weight of strontium in each salt to be the same; and Dr Wollaston proved that three potassium oxalates were obtainable, to form which

a definite amount of potash needed weights of oxalic acid in the proportion of 1 : 2 : 4.

In 1808, the year of the publication of Dalton's *New System of Chemical Philosophy*, Gay-Lussac made known to the world the laws of the combinations of gases by volume—to which his attention had been directed by the discovery which he and A. Von Humboldt had made, that a definite volume of oxygen combined with exactly twice its bulk of hydrogen. He pointed out that there is a simple relation between the volumes of two gases which unite together, and also between their collective volume in the uncombined and in the combined condition. Thus, three volumes of hydrogen combine with one of nitrogen to form two volumes of ammonia; one volume of chlorine with one of hydrogen produces two volumes of hydrochloric acid gas; and two volumes of nitrogen and one of oxygen give two volumes of protoxide of nitrogen. The law of definite proportions was shown to hold good with respect to the volumes as well as to the weights of combining bodies.

In 1811 Avogadro, remarking that equal variations of temperature and pressure produce in all gases and vapours the same changes of volume, enunciated the hypothesis that equal volumes of any gas or vapour contain the same number of atoms, and the same doctrine was brought forward in 1814 by Ampère. On this hypothesis the density of equal volumes of gases was shown to represent the relative weights of their atoms; and thus, as it had been discovered that gases frequently do not unite volume for volume, a distinction came to be drawn between atomic weights and equivalents. If we say atom for volume, wrote Berzelius, we find in Gay-Lussac's discovery one of the most direct arguments in favour of Dalton's hypothesis.

Berzelius (1779–1848), from considerations based on the law of combination by volume, accounted the atoms of elements distinct from their equivalents. Thus two volumes of hydrogen were recognized as the equivalents of one volume of oxygen, the relative weights of equal volumes of the two gases being those of their atoms. Berzelius adopted 100 parts of oxygen as his standard of atomic weight, the atomic weight of hydrogen was therefore 6·24, its equivalent, 12·48. He considered that the atoms of aluminium, arsenic, antimony, bromine, chlorine, fluorine, hydrogen, iodine, nitrogen, and some other elements had a weight equal to only half that of their equivalents, which latter were double and inseparable atoms. In place of the symbols used by Dalton to denote the proportions in which the elements combine by weight, he employed a notation in which letters were used to indicate the names of the elements. He introduced also an abridged notation, in which the equivalents or double atoms were represented by drawing a bar through the symbol of the element. A dot being used to signify an atom of oxygen, the formula of water was written $\text{H}\dot{\text{O}}$; and HCl denoted hydrochloric acid, which was viewed as consisting of a double atom of hydrogen united to a double atom of chlorine,—an hypothesis which left unexplained the fact that the combination of the so-called double atoms of hydrogen and chlorine resulted always in the formation of two molecules, instead of one, of hydrochloric acid gas. Berzelius constructed a table of atomic weights and equivalents, which the discovery by Dulong and Petit in 1819 of the connection between the specific heats and the atomic weights of the elements, and that of the law of isomorphism by Mitscherlich in 1820, enabled him to modify and improve. The equivalent notation of Berzelius was adopted by Gay-Lussac, and displaced in time that founded upon the atomic weights; but it was not generally applied with strictness to all compounds, molecular and not equivalent formulæ being employed in some cases. It had this objection, that it masked the relative atom-fixing

powers of the various acids; thus the formula $\text{AgO} \cdot \text{PO}_3$ did not express the tribasic character of a molecule of phosphoric acid, and its relations to the molecules of acids of less basicity. Observing the ratio between the oxygen of bases and acids, Berzelius was led to the conception of the dualistic theory, according to which all compounds consist of paired constituents or groups of constituents. This theory was applied to both organic and inorganic substances, and received considerable support from the development of the doctrine of compound radicals, of which Berzelius was the chief supporter.

De Morveau, in a memoir *On the Development of the Principles of Methodical Nomenclature*, had in 1787 given the name of *radicles* to the "acidifiable bases" of acids, and Lavoisier in his *Traité Élémentaire* had spoken of the "hydrocarbon radicles" in oils, starch, sugar, and gum. In 1817 Berzelius, following Lavoisier, held the opinion that all inorganic oxides contained simple radicles, and organic oxides compound radicles. In 1832 Liebig and Wöhler discovered the composition of bitter-almond oil, which they showed, on the assumption of the existence of a radicle $\text{C}_7\text{H}_5\text{O}$, might be compared with the compounds of potassium and other metals. Berzelius at first accepted their explanation of the constitution of benzoyl-compounds, but afterwards rejected it, as his electro-chemical theory did not support the view that oxygen could be a constituent of a radicle. Benzoic acid was represented by him as a compound containing the radicle C_7H_5 , thus— $\text{C}_7\text{H}_5\text{O}_2 + \text{HO}$, and alcohol as an oxide of the radicle CH_3 , or $2(\text{CH}_3)\text{O}$.

In 1834 Dumas made known his observations on the substitution of hydrogen by other elements; and Laurent subsequently concluded from numerous experiments that, when hydrogen is substituted by an equivalent of chlorine or bromine, these elements take the place occupied by the hydrogen, performing to a certain extent the functions of the latter in the new compound, which is therefore analogous to that from which it has been produced. Thus was given the first blow to the dualistic theory. The discovery of trichloroacetic acid by Dumas gave considerable aid in the establishment of the new doctrine; but Berzelius and others, who were unable to reconcile with the electro-chemical theory the substitution of an electro-positive by an electro-negative element, sought to explain the facts of substitution in accordance with dualistic notions. Berzelius considered that a compound in which oxygen was a fourth element was at once an oxide and a chloride; trichloroacetic acid was, in his opinion, a copulated compound of sesquichloride of carbon with sesquioxide of carbon (oxalic acid) $\text{C}_2\text{Cl}_3 + \text{C}_2\text{O}_3 + \text{HO}$; acetic acid, on the other hand, was a trioxide of acetyl (C_2H_3) with the formula $\text{C}_2\text{H}_3\text{O}_3 + \text{HO}$. The substitution-compounds discovered by Malaguti and Regnault were in like manner represented dualistically; dichloroformic ether, for example, was written $2\text{C}_2\text{H}_3\text{O}_2 + \text{C}_2\text{H}_3\text{Cl}_2 + 2\text{C}_2\text{H}_3\text{O}_2 + \text{C}_2\text{H}_3\text{Cl}_2$; such complex formulae, however, which implied in most cases a widely different constitution for bodies obviously related in properties, were received with but little favour by chemists. At length Melsens, by converting trichloroacetic acid into acetic acid, gave decisive evidence as to the truth of the principle of the substitution theory.

Gerhardt, who regarded all compounds as simple molecules, certain atoms of which were displaceable by double decomposition, discarded entirely the conception of radicles. He classified organic substances according to the number of carbon atoms contained in their molecules; hence the recognition of homologous series of organic compounds. What he termed *residues*—molecules deprived of certain of their constituents—were in many instances identical with the radicles employed by Berzelius, but were not held necessarily to pre-exist in compounds. Gerhardt

was the means of re-introducing, in a modified form, the atomic notation of Berzelius. Observing that the smallest quantities by weight of carbonic acid gas and water produced in reactions were expressed by the formulae C_2O_4 and H_2O_2 , he concluded that these must represent the molecules of the two bodies, which might be more conveniently written CO_2 and H_2O , the atomic weights of hydrogen, oxygen, and carbon being taken as 1, 16, and 12 respectively. He made the atomic weights of bromine, chlorine, fluorine, hydrogen, iodine, nitrogen, and other of the elements equal to those given by Berzelius, thus enabling the formulae of water and most volatile compounds to be expressed in agreement with the law of Gay-Lussac; but he halved the old atomic weights of most of the metals, supposing that all metallic oxides were similar in constitution to water, or contained two atoms of metal to one of oxygen. Regnault afterwards proved that, according to the law of Dulong and Petit, this alteration ought to be made in the case only of the atomic weights of the metals lithium, potassium, sodium, and silver; many metals were accordingly to be regarded as having oxides of the general formula RO . Such metals, being compared with the diatomic radicles of organic chemistry, were called diatomic by Cannizzaro in 1858. Thus originated the idea of the polyatomicity of the metals.

The theory of types dates from the time of the discovery of trichloroacetic acid by Dumas, who observed that this body and others similarly obtained must be of the same *electric type* with the hydrogenated substances from which they are derived. The discovery by Wurtz of the compound ammonia, and by Hofmann of diethylamine and triethylamine, led to the creation of the *ammonia type*; and Williamson, by the discovery in 1850 of the mixed ethers, was enabled to refer ether, alcohol, and acids to the *ether type*, and to predict the existence of acetic anhydride, which, as well as benzoic anhydride, was discovered in 1852 by Gerhardt. To these types Gerhardt added two others, those of hydrogen and hydrochloric acid, and with the former associated the aldehydes, ketones, and many hydrocarbons, e.g., the radicles discovered by Frankland and Kolbe. The theory of types was still further extended by Williamson, to whom the conception of condensed types is due; by Oilling, who first suggested the idea of representing the relations of compounds by the use of mixed types; and by Kekulé and numerous other investigators.

The foundation of electro-chemical science may be said to have been laid by Nicholson and Carlisle, who in 1800 discovered the decomposition of water by the agency of the voltaic pile; but the earliest electro-chemical experiments were those made by Priestley in 1775 upon ammonia gas, and by Deiman and Van Troestwijk in 1789 upon water, by means of frictional electricity. Cruickshank by experiments with the chlorides of magnesium, sodium, and ammonium demonstrated that when those salts are decomposed by the electric current, alkali always appears at the negative, and acid at the positive pole.

In 1803 Berzelius and Hisinger published their observations on the electrical decomposition of salts and some of their bases; oxygen, acids, and oxidized bases, they said, appear at the positive pole; combustible bodies, alkalies, and earths at the negative. Later experimenters, however, showed that it is the metal, not the oxide, that appears at the negative pole when salts are electrolysed, and that oxides cannot be supposed to exist ready formed in salts. Davy, whose electrical experiments were commenced in 1800, undertook in 1806 a course of investigations which led him to the discovery of the metals of the alkalies and alkaline earths. In 1807 he expressed the opinion that bodies having an affinity for one another are in different states of electricity, and "that chemical and electrical

attractions depend upon the same cause, acting in the one case on particles and in the other on masses of matter."

In 1834 Faraday discovered that the decompositions effected by the voltaic current indicate the quantity by weight in which the elements combine, or the weights of the atoms of the atomic theory, thus adding to the probability of the correctness of the supposition that the operations of the same agent are exhibited in both chemical and electrical phenomena. Latterly, the discovery of the action of the copper-zinc couple by Gladstone and Tribe has opened out a new field of electro-chemical research, already productive of important results. To mention, however, the numerous advances that have been made in recent times, whether in chemical physics or in chemistry proper—especially as regards the constitution and synthesis of the compounds of carbon—would be to exceed the scope of the present introductory notice. The reader must, therefore, be referred to the treatises and original memoirs of those whose labours have effected the modern development of chemistry, and have raised it to the high position which it occupies as a science at the present time. (F. H. B.)

THE ELEMENTS.

The examination of all the various substances met with in nature has led to the discovery of sixty-four different bodies, from which it is impossible by any means *now* at our disposal to separate simpler substances; they are consequently termed "elementary or simple bodies," or "elements." It is not asserted that such substances are absolutely simple, or that they may not be found hereafter to yield more than one kind of matter, but merely that so far as our knowledge extends it is so; indeed, recent spectroscopic researches favour the impression that some at least of the elements are, perhaps, compounds of simpler bodies.

It is the study of the laws which regulate the combination of the elements with one another, and to which their compounds are subject in their mutual actions, and of the properties of the elements and of the compounds formed by their union, which constitutes the science of chemistry.

The majority of the elements are of comparatively rare occurrence, whilst many of them are extremely rare, being met with only in certain localities. Gold and a few others almost always occur as such, and our atmosphere, we know, consists chiefly of the two elements, oxygen and nitrogen, in the free state; also some others, such as carbon, copper, silver, and sulphur, are occasionally met with in the uncombined state, but in general two or more elements are found united. The number of elements of which the materials are made up which principally compose the earth and the plants and animals living upon it is, however, exceedingly small. Thus, plants consist chiefly of carbon, hydrogen, and oxygen, and animals chiefly of these three elements together with nitrogen; water consists entirely of oxygen and hydrogen. The solid earth is mainly composed of substances such as quartz or silica, chalk or limestone, and various silicates like felspar and clay,—the elements which are the chief constituents of these substances being oxygen, silicon, carbon, calcium, magnesium, aluminium, iron, and potassium. The only elements which appear to be absolutely essential to vegetable or animal life are carbon, oxygen, hydrogen, nitrogen, sulphur, phosphorus, calcium, iron, potassium, sodium, magnesium, silicon, and chlorine; and the remainder are to us, so to speak, merely of artificial value.

Four of the elements—chlorine, hydrogen, nitrogen, and oxygen—are gases; and fluorine, which is not known with certainty in the free state, is probably also a gas; two are liquid at ordinary atmospheric temperatures, viz., mercury and bromine; and the element gallium, recently discovered in certain zinc ores, but as yet obtained in only very small

quantities, is also said to be a liquid. The remaining elements are solids.

The following is a list of the elements now known, arranged in alphabetical order. The most important elements are distinguished in the table by capitals; whilst those which at present are of slight importance, on account of their rare occurrence, or of our insufficient knowledge of their properties, are printed in italics.

Name of Element.	Symbol.	Atomic Weight.
ALUMINIUM	Al	27.3
Antimony	Sb (Stibium)	122
Arsenic	As	74.9
Barium	Ba	136.8
Bismuth	Bi	207.5
Boron	B	11
BROMINE	Br	79.75
Cadmium	Cd	111.6
<i>Cesium</i>	Cs	132.7
CALCIUM	Ca	39.9
CARBON	C	11.97
<i>Cerium</i>	Ce	141
CHLORINE	Cl	35.36
Chromium	Cr	52.4
Cobalt	Co	58.6
COPPER	Cu	63.3
<i>Didymium</i>	Di	147
<i>Erbium</i>	Er	(?)170.5
Fluorine	F	19.1
Gallium
<i>Glucinum</i>	G	9.3
Gold	Au (Aurum)	196.2
HYDROGEN	H	1
<i>Indium</i>	In	113.4
IODINE	I	126.53
<i>Iridium</i>	Ir	196.7
IRON	Fe (Ferrum)	55.9
<i>Lanthanum</i>	La	139
LEAD	Pb (Plumbum)	206.4
<i>Lithium</i>	Li	7.01
Magnesium	Mg	23.94
Manganese	Mn	54.8
MERCURY	Hg (Hydrargyrum)	199.8
<i>Molybdenum</i>	Mo	95.8
Nickel	Ni	58.6
<i>Niobium</i>	Nb	91
NITROGEN	N	14.01
<i>Osmium</i>	Os	196.6
OXYGEN	O	15.96
<i>Palladium</i>	Pd	106.2
PHOSPHORUS	P	30.96
Platinum	Pt	196.7
POTASSIUM	K (Kalium)	39.04
<i>Rhodium</i>	Rh	104.1
<i>Rubidium</i>	Rb	85.2
<i>Ruthenium</i>	Ru	100.5
<i>Selenium</i>	Se	79
SILICON	Si	28
SILVER	Ag (Argentum)	107.66
SODIUM	Na (Natrium)	23
Strontium	Sr	87.2
SULPHUR	S	31.98
<i>Tantalum</i>	Ta	182
<i>Tellurium</i>	Te	128
<i>Thallium</i>	Tl	203.64
<i>Thorium</i>	Th	(?)178.5
TIN	Sn (Stannum)	117.8
<i>Titanium</i>	Ti	48
<i>Tungsten</i>	W (Wolfram)	181
<i>Uranium</i>	U	(?)180
<i>Vanadium</i>	V	51.2
<i>Yttrium</i>	Y	(?) 89.5
ZINC	Zn	64.9
<i>Zirconium</i>	Zr	90

Laws of Combination by Weight and Volume—Their explanation by the Atomic Theory—Determination of the relative Weights of Atoms.

The proportions in which elements unite together are definite and constant, a given compound always consisting of the same elements united in the same proportions.

Chloride of silver, for example, in whatever manner it may be prepared, invariably consists of chlorine and silver in the proportions by weight of 35·36 parts of the former and 107·66 of the latter.

But it is often the case that elements combine together in several proportions; whenever this occurs the several proportions in which the one element unites with the other invariably bear a simple relation to one another. Thus, 1 part by weight of hydrogen unites with 8 parts by weight of oxygen, forming water, and with 16 or 8×2 parts of oxygen, forming peroxide of hydrogen. Again, in nitrous oxide we have a compound of 8 parts by weight of oxygen and $1\frac{1}{2}$ of nitrogen; in nitric oxide a compound of 16 or 8×2 parts of oxygen and $1\frac{1}{2}$ of nitrogen; in nitrous anhydride a compound of 24 or 8×3 parts of oxygen and $1\frac{1}{2}$ of nitrogen; in nitric peroxide a compound of 32 or 8×4 parts of oxygen and $1\frac{1}{2}$ of nitrogen; and lastly, in nitric anhydride a compound of 40 or 8×5 parts of oxygen and $1\frac{1}{2}$ of nitrogen. This law is known as the law of combination in multiple proportions.

The proportions in which two elements combine with a third also represent the proportions in which, or in some simple multiple of which, they will themselves combine. For instance, 35·36 parts of chlorine and 79·75 parts of bromine combine with 107·66 parts of silver; and when chlorine and bromine unite it is in the proportion of 35·36 parts of the former to 79·75 parts of the latter. Iodine unites with silver in the proportion of 126·53 parts to 107·66 parts of the latter, but it combines with chlorine in two proportions, viz., in the proportion of 126·53 parts either to 35·36 or to three times 35·36 parts of chlorine. This is known as the law of combination in reciprocal proportions.

In explanation of these three laws deduced entirely from experimental observations, chemists have adopted the atomic or molecular theory which was first introduced into the science by Dalton at the commencement of this century. According to this theory the exceedingly small masses or *molecules* of which it is supposed matter consists are composite, being made up of indivisible particles or *atoms* (see the article *ATOM*, vol. iii. p. 36). The molecules of the elements are assumed to consist of similar atoms, whereas those of compounds are congeries of dissimilar atoms; and the molecules which constitute a given kind of matter, it is supposed, are alike in weight and general properties, but differ from those of which all other kinds of matter are composed, so that every molecule belongs to one of a definite number of species. The study of the alterations which take place in the composition of molecules under the influence of various forces, and which result from their action upon one another, is the work of the chemist; whilst it is the province of the physicist to study the influences of those forces upon matter which affect entire molecules without in any way altering their composition.

The chemist has no means of ascertaining, nor does he attempt to ascertain, the absolute weights of the atoms or of the molecules of the various elements and their compounds: he concerns himself merely with their relative weights, hydrogen being adopted as the standard of reference since it is the lightest of all known elements. The relative weight of the atoms of the various elements referred to that of hydrogen regarded as 1 are given in the third column of the table on page 467. The determination of the exact atomic weight of an element is an operation of extreme difficulty, and one requiring the greatest analytical skill, so that as yet the atomic weights of only a limited number of elements have been ascertained with more than approximate accuracy. The most accurately determined atomic weights are those of hydrogen, oxygen, nitrogen, chlorine, bromine, iodine, lithium, potassium,

sodium, silver, and thallium. Apparently the numbers obtained for these elements are practically perfect.

The manner in which the relative weights of the atoms of the elements are determined will be evident from the following considerations.

If, instead of comparing together the relative weights of the elements which enter into combination, the volumes which they occupy in the state of gas (at the same temperature and under the same pressure) before and after combination are compared, it is found that gases always unite together in very simple proportions, viz., either in equal volumes, or in volumes which bear some simple relation such as 1 : 2, 1 : 3, 1 : 4, 2 : 3, &c. Moreover, whatever the number of volumes before combination, it always is reduced to two on combination. Thus, equal volumes of hydrogen and chlorine gases unite without condensation to form hydrochloric acid gas; in the production of water 2 volumes of hydrogen and 1 of oxygen combine, but form only 2 volumes of water-gas or steam; and if ammonia gas be decomposed by heat or a series of electric sparks, 2 volumes of the gas yield 3 volumes of hydrogen and 1 of nitrogen.

Now, according to the law of Boyle and Mariotte, the volume of a given mass of any gas varies inversely as the pressure, provided that the temperature remains the same; for instance, the quantity of air which is contained in a vessel of the capacity of 1 pint under the pressure of 1 atmosphere, or 15 lb upon the square inch, may be contained in a vessel of half a pint capacity if the pressure be doubled.

According to the law of Charles and Gay-Lussac, on the other hand, all gases expand equally by heat, provided the pressure remains constant,—the rate of expansion being $\frac{1}{273}$ of the volume at 0° C. for each rise of 1° C. in temperature; or in other words, the volume of a gas varies directly as the absolute temperature.

A gas which strictly conforms to these two laws is said to be a perfect gas, but none of the gases with which we are acquainted are perfect in this sense. Thus, Andrews's experiments show that carbonic anhydride, which under a pressure of 36 atmospheres at 0° C. is reduced to the liquid state, condenses more than it should according to Boyle's law. Again, the density of chlorine gas referred to air, according to Stas's determination of the atomic weight of this element, should be 2·4501. The following table exhibits its density at various temperatures from 20° to 200° C.,¹ and it is evident that it is higher than it should be at all temperatures below 200° C.:

Temperature.	Density.	Temperature.	Density.
20°	2·4807	150°	2·4609
50°	2·4783	200°	2·4502
100°	2·4685		

From the few accurate observations which have been made on this subject it appears that, in general, the departure from the laws of Boyle and Charles is greater the more the temperature of the gas approaches to that at which it becomes liquid; and chlorine affords an instructive illustration of this, since it is readily condensed to a liquid under the pressure of 4 atmospheres at 15°·5 C., or by cooling in a bath of solid carbonic anhydride and ether.

The general resemblance in the behaviour of gases under the influence of pressure and heat is very great, however, although not in absolute accordance with the laws of Boyle and Charles; by this we are led to the assumption that their physical constitution must be similar, and, therefore, to the acceptance of the proposition, originally stated by Avogadro in 1811, that equal volumes of different gases contain equal numbers of molecules. Obviously, therefore, if the relative weights of equal volumes of different gases are determined under the same conditions as to tempera-

¹ Ludwig, *Berichte der deutschen chemischen Gesellschaft*, 1863, 232.

ture and pressure, the temperature and pressure chosen being that at which the gases most closely approximate to the requirements of the laws above stated, an estimate of the relative weights of their molecules is obtained. For example, the density of nitrogen referred to hydrogen is 1.4, since a given volume of nitrogen is found to weigh 1.4 times as much as an equal volume of hydrogen at the same temperature and under the same pressure; hence, according to Avogadro's hypothesis, the molecules of nitrogen are fourteen times as heavy as the hydrogen molecules.

In the formation of hydrochloric acid gas equal volumes of chlorine and hydrogen unite without condensation. The density of chlorine gas referred to hydrogen is 35.36, and the simplest possible hypothesis of the composition of hydrochloric acid is that it consists of an atom of hydrogen weighing 1, and an atom of chlorine weighing 35.36, so that its molecule, therefore, must weigh 35.36. But since the density of hydrochloric acid gas is ascertained by experiment to be only 18.18 as compared with that of hydrogen, and, according to Avogadro's hypothesis, equal volumes of hydrogen and hydrochloric acid gas contain equal numbers of molecules, it follows that the weight of the hydrogen molecule as compared with that of hydrochloric acid must be 2, or in other words, *that the hydrogen molecule consists of two atoms*. The chlorine molecule in like manner must consist of two atoms, each weighing 35.36, and in the formation of hydrochloric acid from hydrogen and chlorine two molecules of hydrochloric acid are produced from a molecule of hydrogen and a molecule of chlorine: in the one molecule half the hydrogen is displaced by chlorine, in the other half the chlorine is displaced by hydrogen. It may be proved that the assumption is correct that the molecule of hydrochloric acid contains only a single atom of chlorine, weighing 35.36, and that it does not consist, for example, of two atoms of chlorine each weighing 17.68, by comparing the various volatile compounds containing chlorine. In the first place their densities in the state of gas are determined, and a knowledge is thus obtained of the relative weights of their molecules as compared with that of the hydrogen molecule; the percentage of chlorine they contain is then ascertained by careful analysis. The density referred to hydrogen as unity multiplied by 2 gives the molecular weight of the compound; and the percentage of chlorine being known, the amount contained in the quantity expressed by the molecular weight is ascertained by a simple calculation. For example, the density of sulphur chloride is found to be 57.36, and its molecular weight is therefore 57.36×2 or 114.72; it contains 61.64 per cent. of chlorine, so that in 114.72 parts there are 70.72 of chlorine. When the numbers thus deduced are compared it is seen that the lowest amongst them is 35.36, and that all the higher numbers are simple multiples of this; 35.36 is accordingly adopted as the number which expresses the weight of the atom of chlorine relatively to that of the hydrogen atom. A number of volatile chlorine compounds are thus compared in the following table:—

Name of Compound.	Molecular Weight.	Weight of Chlorine.
Hydrochloric acid	35.36	35.36
Methyl chloride	50.33	35.36
Carbon oxychloride.....	98.65	35.36×2
Mercuric chloride.....	270.52	35.36×2
Boron chloride.....	117.03	35.36×3
Phosphorus trichloride..	137.04	35.36×3
Carbon tetrachloride....	153.41	35.36×4
Silicon tetrachloride....	169.44	35.36×4
Aluminium chloride	266.70	35.36×6
Chlorine.	70.72	35.36×2

In like manner, on comparing the various volatile compounds which contain oxygen, it is found that the number 16 represents the least weight of oxygen contained in the molecular weight of any of its compounds; 16 is therefore taken as the atomic weight of oxygen.

In all cases in which it is possible to obtain volatile compounds, the atomic weights of elements may be deduced in this manner; unfortunately, however, many of the elements do not furnish stable volatile compounds, so that hitherto the atomic weights of the following elements only have been ascertained by the application of Avogadro's hypothesis:—

Antimony.	Iodine.	Silicon.
Arsenic.	Lead.	Sulphur.
Bismuth.	Mercury.	Tantalum.
Boron.	Molybdenum.	Tellurium.
Bromine.	Niobium.	Tin.
Carbon.	Nitrogen.	Titanium.
Chlorine.	Osmium.	Tungsten.
Chromium.	Oxygen.	Vanadium.
Fluorine.	Phosphorus.	Zinc.
Hydrogen.	Selenium.	Zirconium.

The determination of the density of bodies in the state of gas is thus an operation of fundamental importance. The precise manner in which the determination is effected is described in most of the text-books on chemistry. The methods ordinarily employed in the case of liquids and solids which by the application of heat can be converted into vapour or gas without undergoing decomposition are known respectively as Dumas's and Gay-Lussac's, a modification of the latter method of great value has recently been introduced by Hofmann. By Dumas's method the weight of substance is ascertained which will furnish a certain volume of gas at a certain temperature and pressure; by Gay-Lussac's method, however, and by Hofmann's modification of it, the volume of gas is measured which is furnished by a given weight of the substance at a certain temperature and pressure. By either method we arrive finally at a knowledge of the weight (w) of a certain volume (v) of the gas at a temperature t and pressure p ; and its density (D) referred to hydrogen is then found by dividing the weight w by the weight (w') of an equal volume of hydrogen at the same temperature t and pressure p —

$$D = \frac{w}{w'}$$

Or the density referred to air may be calculated in a similar manner, and then converted into the density referred to hydrogen by multiplication by 1.43,—the number which expresses the density of air referred to hydrogen. Both methods require that the substance be heated to the temperature at which its vapour most closely approximates to the laws of Boyle and Charles, which is readily ascertained by experiment; this temperature, however, is often very considerably above the boiling point of the substance, and acetic acid may be cited as an illustration of this. Thus, although this acid boils at 119° C., its vapour does not exhibit the required density until it is heated to 250° C., as will be evident from the following table—the theoretical vapour density of acetic acid vapour referred to hydrogen being about 30:—

Temperature.....	125°	130°	140°	160°	190°	250°	300°
Vapour Density....	46.1	45.0	41.8	35.7	33.1	30.01	30.01

Owing to unavoidable experimental errors, and, in many cases, probably to the circumstance that the vapours of solid and liquid bodies are very imperfect gases at temperatures not much above their boiling points, the determination of the vapour density of a substance does not, as a rule, furnish a result of more than approximate accuracy,—the result being the more accurate, however, the more rarefied the vapour and the higher the temperature at which the

density is determined, provided always that the temperature be not so high as to cause decomposition. But the relative proportions in which the elements combine, and the composition of compounds may usually be ascertained with very great—in many cases with almost absolute—accuracy by chemical analysis; and the determination of the density in the state of gas simply serves to prove which of the several multiple proportions, in which it is found that the elements combine together, is the true atomic weight. For instance, analysis shows that marsh gas is a compound of carbon and hydrogen exactly in the proportions of 1 part of the latter with 3 of the former; that carbonic anhydride consists of carbon and oxygen in the proportion of 16 parts or an atom of the latter and 6 or 3×2 parts of carbon; and carbonic oxide of the same elements, in the proportion, however, of 16 of oxygen and 12 or 3×4 of carbon. The question, therefore, is, Which of the numbers, 3, 6, or 12, represents the relative weight of the carbon atom; that is to say, is marsh gas a compound of an atom of hydrogen and an atom of carbon weighing 3, of two atoms of hydrogen and an atom of carbon weighing 6, or of four atoms of hydrogen and an atom of carbon weighing 12? The molecular weights of these three compounds would be respectively $3+1$ or 4, $6+2$ or 8, and $12+4$ or 16; and the corresponding theoretical densities referred to hydrogen 2, 4, and 8. Finding, however, by experiment that the density of marsh gas is, say, 7.5, we at once conclude that the atomic weight of carbon is 12 and not 6 or 3, because the observed density of marsh gas most closely accords with that required on this assumption. The difference between theory and experiment is practically seldom, if ever, so large as in this case, which is merely given as an illustration of the principle involved.

The equivalent of an element—that is to say, the amount of it which is capable of combining with or displacing one part by weight, or one atom, of hydrogen—being known, its atomic weight is not absolutely fixed by the determination of the density in the state of gas of its compounds with other elements; we are at most enabled to say from this that the atomic weight cannot exceed a certain value,—for instance, that the atomic weight of chlorine cannot exceed 35.36, because all its compounds contain either this amount or some simple multiple of it in their molecules. It is nevertheless possible that 35.36 is not the weight of one but of several atoms of chlorine; the probability that 35.36 is the true atomic weight is enormously increased, however, as compound after compound is examined and found to contain 35.36 or some simple multiple of 35.36 parts of chlorine in its molecule.

In the case of those elements of which stable volatile compounds have not been obtained, the study of their specific heats is of great importance, and moreover furnishes most important confirmation of the atomic weights deduced by the aid of Avogadro's hypothesis. To raise the temperature of equal weights of different substances the same number of degrees, from 0° to 1° C. for instance, very different amounts of heat are required; and on the other hand very different amounts of heat are given out when equal weights of different substances are cooled from the initial temperature t° to a lower temperature t'° . Of all bodies except hydrogen water has the greatest capacity for heat, and is, therefore, adopted as the standard of reference,—the number which expresses the amount of heat necessary to raise the temperature of a given weight of a body a certain number of degrees, or which is given out by it in cooling through a certain number of degrees, as compared with that required to raise the temperature of an equal weight of water the same number of degrees, being termed its specific heat. Thus, the specific heat of lithium is .9408; that is to say, to raise the temperature of a given

weight of lithium—1 gramme, for example—from 0° to 1° C. only requires .9408 of the heat necessary to raise the temperature of 1 gramme of water from 0° to 1° C. The specific heats in the solid state of the various elements of which the atomic weights have been determined by Avogadro's hypothesis are given in the second column of the following table:—

Name of Element.	Specific Heat.	Atomic Weight.	Specific Heat Multiplied by Atomic Weight.
Antimony.....	.0508	122	6.19
Arsenic.....	.0814	74.9	6.10
Bismuth.....	.0308	207.5	6.39
Boron.....	.5	11	5.5
Bromine.....	.0843	79.75	6.72
Carbon.....	.4589	11.97	5.49
Iodine.....	.0541	126.53	6.84
Lead.....	.0314	206.4	6.48
Mercury.....	.0317	199.8	6.33
Molybdenum.....	.0722	95.8	6.92
Osmium.....	.0311	198.6	6.17
Phosphorus.....	.174	30.96	5.39
Selenium.....	.0745	79	5.86
Silicon.....	.2029	28	5.68
Sulphur.....	.171	31.98	5.47
Tellurium.....	.0474	128	6.07
Tin.....	.0562	117.8	6.62
Tungsten.....	.0334	184	6.14
Zinc.....	.0955	64.9	6.19

On comparing the numbers in the fourth column of this table it will be seen that they vary within comparatively narrow limits; and if certain of the elements are excepted, viz., boron, carbon, phosphorus, sulphur, silicon, and selenium, the agreement becomes much closer, the average product obtained by multiplying specific heat into atomic weight being about 6.3. From this it would appear that the specific heats of these elements are, at least approximately, inversely proportional to their atomic weights. From the observation of this relation in the case of only a small number of elements Dulong and Petit, in 1811, were led to infer that the atoms of all simple bodies have the same capacity for heat. The specific heat of a body varies, however, with the temperature; an extreme instance of this is afforded by the elements carbon, boron, and silicon, as will be evident on inspecting the following table of the specific heat of carbon in the form of diamond at various temperatures:—

Temperature.....	0°	50°	100°	150°	200°	606°	806°	985°
Specific Heat.....	.095	.144	.191	.236	.279	.440	.448	.453
Product of Atomic Wt. and Specific Heat..	1.12	1.72	2.28	2.81	3.33	5.26	5.36	5.48

Hence, owing to the circumstances that the determinations of specific heat have not been made at temperatures which are comparable for the different elements, there is no doubt that many of the results which have been obtained are defective; but from Weber's recent researches it appears that in the case of the solid elements there is a point for each element, after which the increase in specific heat with increase of temperature is insignificant, and when this point is reached the product of specific heat into atomic weight—the so-called atomic heat—varies within comparatively narrow limits. These limits, according to Weber, are from 5.5 to 6.5, but it appears probable that the superior limit is slightly greater than this, and as a matter of fact the atomic heats of nearly all the elements are nearer 6.5 than 5.5,—the latter number being characteristic of the so-called non-metallic elements, the atomic weights of which can be determined by the aid of Avogadro's hypothesis.

In consequence of this relation between the specific heat of an element and its atomic weight, we can readily deter-

mine the atomic weights of elements which do not furnish volatile compounds, it being merely necessary to ascertain the equivalent of the element by analyzing its compounds, and to multiply the equivalent by such a number that the product when multiplied by the specific heat of the element will furnish a number not less than 5.5, and not much greater than 6.5. As an instance of the application of the method, the metal indium, one of the most recently discovered elements, may be cited. Analysis showed that the equivalent of indium was 37.8, but this number was doubled on account of the many points in which indium resembles zinc,—the latter metal having the equivalent 32.45, but the atomic weight 64.9. For some time, until Bunsen determined its specific heat, 75.6 was accepted as the atomic weight of indium, but he found that it was necessary to multiply the equivalent by 3 in order that the product of specific heat into atomic weight should correspond to that ordinarily observed, thus raising the atomic weight to 113.4.

The following table is a list of the elements whose atomic weights have been determined from the observation of their specific heats alone:—

Name of Element.	Specific Heat.	Atomic Weight.	Atomic Heat.
Aluminium214	27.3	5.8
Cadmium.....	.0567	111.6	6.3
Calcium.....	.170	39.9	6.8
Cerium.....	.0417	141	6.2
Chromium.....	.100	52.4	5.2
Cobalt.....	.107	58.6	6.3
Copper.....	.0952	63.3	6.0
Didymium.....	.0456	147	6.7
Gincium.....	.61	9.3	5.9
Gold.....	.0324	196.2	6.4
Indium.....	.0570	113.4	6.5
Iridium.....	.0326	196.7	6.4
Iron.....	.111	55.9	6.4
Lanthanum.....	.0448	139	6.2
Lithium.....	.9408	7.01	6.6
Magnesium.....	.250	23.94	6.0
Manganese.....	.122	51.8	6.7
Nickel.....	.109	58.6	6.4
Palladium.....	.0593	106.2	6.3
Platinum.....	.0324	196.7	6.4
Potassium.....	.166	39.04	6.5
Rhodium.....	.0583	104.1	6.1
Ruthenium.....	.0611	102.5	6.3
Silver.....	.0570	107.66	6.1
Sodium.....	.293	23	6.7
Thallium.....	.0335	203.64	6.8

The only elements of which at present the atomic weights have not been ascertained, either by the vapour-density or specific heat method, are erbium, thorium, uranium, and yttrium. Even the equivalent of gallium is not yet known.

Often, also, information which is of service in determining the atomic weights of elements may be obtained by observing the manner in which their compounds crystallize, for it is found that in many instances a given element in a compound may be displaced by another without altering the crystalline form; for example, in ordinary alum, which is a double sulphate of potassium and aluminium, the potassium may readily be displaced by sodium, or the aluminium by chromium, and yet the resulting compounds crystallize in precisely the same manner as the alum. Substances which thus agree in crystalline form are said to be *isomorphous*. A great number of isomorphous substances have been examined by chemists; and they have been led to infer that, as a rule, when two compounds containing similar elements agree in crystalline form they contain the same number of atoms; and hence the quantity of an element which is capable of displacing an atom of another

element in a compound without altering its crystalline form is regarded as its atomic weight. This is by no means always the case, however, and the occurrence of isomorphism cannot alone be taken as a proof of the atomic weight of an element; it is of service rather as a check on the determinations made in other ways, and as a stimulus to investigation in the case of elements which have not been sufficiently examined. For instance, certain phosphorous and arsenic minerals of similar composition were known to be isomorphous with a vanadium mineral, vanadinite, the composition of which, according to the received atomic weight of vanadium, exhibited no analogy with them. Roscoe was led by this to investigate anew the compounds of vanadium and to determine its atomic weight, and he found that what had hitherto been regarded as vanadium was really an oxide of the element, and that when the composition of the mineral vanadinite was calculated from the true atomic weight of vanadium, it was precisely similar to that of the minerals with which it was known to be isomorphous.

Molecular Weights.

We have pointed out (p. 469) that it is to be supposed that the molecule of hydrogen consists of two atoms; hence, if the atomic weight of hydrogen be taken as 1 its molecular weight is 2. In order to ascertain the molecular weights of other elements—that is to say, the relative weights of their molecules referred to that of hydrogen—it is merely necessary to determine their densities referred to hydrogen as unity, and then to multiply the densities by 2. Unfortunately, owing to the high temperature at which most of the elements are converted into vapour, the densities of only very few of them are as yet known.

When, however, the molecular weights of the elements are compared with their atomic weights it is found that they are not always, as in the case of hydrogen, double their atomic weights; hence it is inferred that the molecules of elements do not all contain two atoms. In a few cases the atomic weight and molecular weight agree, which necessitates the conclusion that the molecules are monatomic or consist of a single atom; in a few other cases the molecular weight is either 4 or 6 times the atomic weight, and the molecules are therefore regarded as tetraatomic or hexatomic.

The following table includes all the elements of which the molecular weights have been determined:—

Name.	Atomic Weight.	Molecular Weight.	No of Atoms in Molecule.
Hydrogen	1	2	2
Chlorine.....	35.36	70.74	2
Bromine.....	79.75	159.50	2
Iodine.....	126.53	253.06	2
Nitrogen	14.01	28.02	2
Oxygen.....	15.96	31.92	2
Selenium.....	79	158	2
Tellurium.....	128	256	2
Mercury.....	199.8	199.8	1
Cadmium.....	111.6	111.6	1
Phosphorus.....	30.94	123.76	4
Arsenic.....	74.9	299.6	4
Sulphur.....	31.93	63.96	2
		191.88	6

It will be seen that two numbers are given for sulphur. This is because at temperatures above 800° C. the density of sulphur vapour is such as to indicate that the sulphur molecule consists of 2 atoms, whereas its density at about 500° C. is three times as great, and, consequently, it is to be supposed that the molecules are hexatomic. Selenium, which is closely allied to sulphur, exhibits a very similar behaviour, its vapour at about 1400° C. containing only diatomic molecules, but as the temperature sinks its density

¹ This number is known to be too low.

rapidly increases. These two elements, in fact, afford striking examples of the resolution of complex molecules into simpler molecules by heat; and it is by no means improbable that the tetratomic phosphorus and arsenic molecules will be found to behave similarly if sufficiently heated.

No method is known by which it is possible to determine the molecular weights of elements or compounds in any other state than that of gas, and the behaviour of sulphur is alone sufficient to prove that we are not justified in assuming that the molecular weights of liquid or solid elements or compounds are identical with their molecular weights as gases. Indeed it is in the highest degree probable that the molecules of solid and liquid bodies are very frequently far more complex than the molecules of the same bodies in the state of gas.

Chemical Notation—Valency of Elements—Rational Formulæ.

Opposite the name of each element in the second column of the table on p. 467, the symbol is given which is always employed to represent it. This symbol, however, not only represents the particular element, but a certain definite quantity of it. Thus, the letter H always stands for 1 atom or 1 part by weight of hydrogen, the letter N for 1 atom or 14 parts of nitrogen, and the symbol Cl for 1 atom or 35·36 parts of chlorine. Compounds are in like manner represented by writing the symbols of their constituent elements side by side, and if more than one atom of each element be present, the number is indicated by a numeral placed on the right of the symbol of the element either below or above the line. Thus, hydrochloric acid is represented by the formula HCl, that is to say, it is a compound of an atom of hydrogen with an atom of chlorine, or of 1 part by weight of hydrogen with 35·36 parts by weight of chlorine; again, sulphuric acid is represented by the formula H_2SO_4 , which is a statement that it consists of 2 atoms of hydrogen, 1 of sulphur, and 4 of oxygen, and consequently of certain relative weights of these elements. A figure placed on the right of a symbol only affects the symbol to which it is attached, but when figures are placed in front of several symbols all are affected by it, thus $2\text{H}_2\text{SO}_4$ means H_2SO_4 taken twice.

The distribution of weight in chemical change is readily expressed in the form of equations by the aid of these symbols; the equation

for example, is to be read as meaning that from certain definite weights of hydrochloric acid and zinc certain definite weights of two different bodies, zinc chloride and hydrogen, are produced. The + sign is invariably employed in this way either to express combination or action upon, the meaning usually attached to the use of the sign = being that from such and such bodies such and such other bodies are formed.

Usually, when the symbols of the elements are written or printed with a figure to the right, it is understood that this indicates a molecule of the element, the symbol alone representing an atom. Thus, the symbols H_2 and P_4 indicate that the molecules of hydrogen and phosphorus respectively contain 2 and 4 atoms. Since, according to the molecular theory, in all cases of chemical change the action is between molecules, such symbols as these ought always to be employed. Thus, the formation of hydrochloric acid from hydrogen and chlorine is correctly represented by the equation

that is to say, a molecule of hydrogen and a molecule of chlorine give rise to two molecules of hydrochloric acid; whilst the following equation merely represents the relative

weights of the elements which enter into reaction, and is not a complete expression of what is supposed to take place:—

As the molecular weights of comparatively few of the elements have been determined, however, it is possible only in a limited number of cases to employ such symbols. The molecular weights of the larger number of compounds are also unknown, but in all cases it is usual to represent them by formulæ which to the best of our knowledge express their molecular composition in the state of gas, and not merely the relative number of atoms which they contain; thus, acetic acid consists of carbon, hydrogen, and oxygen in the proportion of one atom of carbon, two of hydrogen, and one of oxygen, but the determination of its vapour density shows that it has a molecular weight corresponding to the formula $\text{C}_2\text{H}_4\text{O}_2$, which therefore is always employed to represent acetic acid. When chemical change is expressed with the aid of molecular formulæ, not only is the distribution of weight represented, but from mere inspection of the symbols it is possible to deduce the relative volumes which the agents and resultants occupy in the state of gas if measured at the same temperature and under the same pressure. Thus, the equation

not only represents that certain definite weights of hydrogen and oxygen furnish a certain definite weight of the compound which we term water, but that if the water in the state of gas, the hydrogen, and the oxygen are all measured at the same temperature and pressure, the volume occupied by the oxygen is only half that occupied by the hydrogen, whilst the resulting water-gas will only occupy the same volume as the hydrogen. In other words, 2 volumes of oxygen and 4 volumes of hydrogen furnish 4 volumes of water gas. A simple equation like this, therefore, when properly interpreted, affords a large amount of information. One other instance may be given; the equation

represents the decomposition of ammonia gas into nitrogen and hydrogen gases by the electric spark, and it not only conveys the information that a certain relative weight of ammonia consisting of certain relative weights of hydrogen and nitrogen is broken up into certain relative weights of hydrogen and nitrogen, but also that the nitrogen will be contained in half the space which contained the ammonia, and that the volume of the hydrogen will be one and a half times as great as that of the original ammonia, so that in the decomposition of ammonia the volume becomes doubled.

Formulæ which merely express the relative number of atoms of the different elements present in a compound are termed empirical formulæ, and the formulæ of all compounds whose molecular weights are undetermined are necessarily empirical. The molecular formula of a compound, however, is always a simple multiple of the empirical formula, if not identical with it; thus, the empirical formula of acetic acid is CH_3O , and its molecular formula is $\text{C}_2\text{H}_4\text{O}_2$, or twice CH_3O . If the vapour density of a compound cannot be ascertained, its molecular formula can only be ascertained, with more or less approximation to truth, by considering its properties, and especially its relations to allied compounds of known molecular weight. For example, chromic anhydride is represented as CrO_3 , and, although it cannot be vaporized, this is held to be its molecular formula chiefly on account of the formation from chromic anhydride of a volatile chromium oxychloride, the molecular weight of which is found to accord with the formula CrO_3Cl_2 .

But in addition to empirical and molecular formulæ.

chemists are in the habit of employing various kinds of rational formulæ, called constitutional formulæ, graphic formulæ, &c., which not only express the molecular composition of the compounds to which they apply, but also embody certain assumptions as to the manner in which the constituent atoms are arranged, and convey more or less information with regard to the nature of the compound itself, viz., the class to which it belongs, the manner in which it is formed, and the behaviour it will exhibit under various circumstances. Before explaining these formulæ it will be necessary, however, to consider the differences in combining power exhibited by the various elements.

It is found that the number of atoms of a given element, of chlorine, for example, which unite with an atom of each of the other elements is very variable. Thus, hydrogen unites with but a single atom of chlorine, zinc with two, boron with three, silicon with four, and phosphorus with five. Those elements which are equivalent in combining or displacing power to a single atom of hydrogen are said to be *univalent* or *monad* elements; whilst those which are equivalent to two atoms of hydrogen are termed *bivalent* or *dyad* elements; and those equivalent to three, four, five, or six atoms of hydrogen triad, tetrad, pentad, or hexad elements. But not only is the combining power or valency (atomicity) of the elements different, it is also observed that one element may combine with another in several proportions, or that its valency may vary; for example, phosphorus forms two chlorides represented by the formulæ PCl_3 and PCl_5 , and nitrogen the series of oxides represented by the formulæ

In explanation of these facts it is supposed that each element has a certain number of "units of affinity," which may be entirely, or only in part, engaged when it enters into combination with other elements; and in those cases in which the entire number of units of affinity are not engaged by other elements, it is supposed that those which are thus disengaged neutralize each other, as it were. For example, in pentachloride of phosphorus the five units of affinity possessed by the phosphorus atom are satisfied by the five monad atoms of chlorine, but in the trichloride two are disengaged, and, it may be supposed, satisfy each other. Compounds in which all the units of affinity of the contained elements are engaged are said to be *saturated*, whilst those in which the affinities of the contained elements are not all engaged by other elements are said to be *unsaturated*. According to this view, it is necessary to assume that, in all unsaturated compounds, two, or some even number of affinities are disengaged; and also that all elements which combine with an even number of monad atoms cannot combine with an odd number, and *vice versa*,—in other words, that the number of units of affinity active in the case of any given element must be always either an even or an odd number, and that it cannot be at one time an even and at another an odd number. There are, however, a few remarkable exceptions to this "law." Thus, it must be supposed that in nitric oxide, NO, an odd number of affinities are disengaged, since a single atom of dyad oxygen is united with a single atom of nitrogen, which in all its compounds with other elements acts either as a triad or pentad. When nitric peroxide, N_2O_4 , is converted into gas, it decomposes, and at about 180°C . its vapour entirely consists of molecules of the composition NO_2 ; while at temperatures between this and 0°C . it consists of a mixture in different proportions of the two kinds of molecules, N_2O_4 and NO_2 . The oxide NO_2 must be regarded as another instance of a compound in which an odd number of affinities of one of the contained elements are disengaged, since it contains two atoms of dyad oxygen united with a single

atom of triad or pentad nitrogen. Again, when hexachloride of tungsten is converted into vapour it is decomposed into chlorine and a pentachloride, having a normal vapour density, but as in the majority of its compounds tungsten acts as a hexad, we apparently must regard its pentachloride as a compound in which an odd number of free affinities are disengaged. Hitherto no explanation has been given of these exceptions to what appears to be a law of almost universal application, viz., that the sum of the units of affinity of all the atoms in a compound is an even number.

The number of units of affinity active in the case of any particular element is largely dependent, however, upon the nature of the element or elements with which it is associated. Thus, an atom of iodine only combines with one of hydrogen, but may unite with three of chlorine, which never combines with more than a single atom of hydrogen; an atom of phosphorus unites with only three atoms of hydrogen, but with five of chlorine, or with four of hydrogen and one of iodine; and the chlorides corresponding to the higher oxides of lead, nickel, manganese, and arsenic, PbO_2 , Ni_2O_3 , MnO_2 , and As_2O_5 do not exist as stable compounds, but only the lower chlorides, PbCl_2 , NiCl_2 , MnCl_2 , and AsCl_3 , are known.

It is difficult, therefore, to classify the elements according to their valencies; indeed, an absolute classification is scarcely possible. In the following table a number of the elements are arranged mostly according to their apparent maximum valencies:—

<i>Monads.</i>	<i>Dyads.</i>	<i>Triads.</i>
Hydrogen.	Oxygen.	Boron.
Fluorine.	Barium.	Gold.
Chlorine.	Strontium.	
Bromine.	Calcium.	
Iodine.	Magnesium.	
Potassium.	Zinc.	
Sodium.	Cadmium.	
Lithium.	Copper.	
	Mercury.	
Silver.		
<i>Tetrads.</i>	<i>Pentads.</i>	<i>Hexads.</i>
Carbon.	Nitrogen.	Sulphur.
Silicon.	Phosphorus.	Selenium.
Tin.	Arsenic.	Tellurium.
Lead.		
Aluminium.	Antimony.	Tungsten.
Indium.	Bismuth.	Molybdenum.
Thallium.		
Iron.		
Chromium.		
Manganese.		
Cobalt.		
Nickel.		
Platinum.		
Palladium.		

The valency of an element is usually expressed by dashes or Roman numerals placed on the right of its symbol, thus: H', O'', B''', C'', P'', Mo''; but in constructing graphic formulæ the symbols of the elements are written with as many lines attached to each symbol as the element which it represents has units of affinity.

Graphic formulæ are employed to express the manner in which it is assumed that the constituent atoms of compounds are associated together; for example, the trioxide of sulphur is usually regarded as a compound of an atom of hexad sulphur with three atoms of dyad oxygen, and this hypothesis is illustrated by the graphic formula

When this oxide is brought into contact with water it combines with it forming sulphuric acid, H_2SO_4 , and it is

supposed that in this compound only two of the oxygen atoms are wholly associated with the sulphur atom, each of the remaining oxygen atoms being united by one of its affinities to the sulphur atom, and by the remaining affinity to an atom of hydrogen; thus—

Again, the reactions of acetic acid, $\text{C}_2\text{H}_4\text{O}_2$, show that the four atoms of hydrogen which it contains have not all the same function, and also that the two atoms of oxygen have different functions; the graphic formula which we are led to assign to acetic acid, viz.,—

serves in a measure to express this, three of the atoms of hydrogen being represented as associated with one of the atoms of carbon, whilst the fourth atom is associated with an atom of oxygen which is united by a single affinity to the second atom of carbon, to which, however, the second atom of oxygen is united by both of its affinities. It is not to be supposed that there are any actual bonds of union between the atoms; graphic formulæ such as these merely express the hypothesis that certain of the atoms in a compound come directly within the sphere of attraction of certain other atoms, and only indirectly within the sphere of attraction of others,—an hypothesis to which chemists are led by observing that it is often possible to separate a group of elements from a compound, and to displace it by other elements or groups of elements.

Rational formulæ of a much simpler description than these graphic formulæ are generally employed. For instance, sulphuric acid is usually represented by the formula $\text{SO}_2(\text{OH})_2$, which indicates that it may be regarded as a compound of the group SO_2 with twice the group OH . Each of these OH groups is equivalent in combining or displacing power to a monad element, since it consists of an atom of dyad oxygen associated with a single atom of monad hydrogen, so that in this case the SO_2 group is equivalent to an atom of a dyad element. This formula for sulphuric acid, however, merely represents such facts as that it is possible to displace an atom of hydrogen and an atom of oxygen in sulphuric acid by a single atom of chlorine, thus forming the compound SO_2HCl ; and that by the action of water on the compound SO_2Cl_2 twice the group OH , or water minus an atom of hydrogen, is introduced in place of the two monad atoms of chlorine—

Constitutional formulæ like these, in fact, are nothing more than symbolic expressions of the character of the compounds which they represent, the arrangement of symbols in a certain definite manner being understood to convey certain information with regard to the compounds represented.

Groups of two or more atoms like SO_2 and OH , which are capable of playing the part of elementary atoms (that is to say, which can be transferred from compound to compound), are termed compound radicles, the elementary atoms being simple radicles. Thus, the atom of hydrogen is a monad simple radicle, the atom of oxygen a dyad simple radicle, whilst the group OH is a monad compound radicle.

It weights of the elements which enter into reaction, and is not upon complete expression of what is supposed to take place:—

say, a complete molecular weights of comparatively few of the atoms have been determined, however, it is possible thus a limited number of cases to employ such

The molecular weights of the larger number of are also unknown, but in all cases it is usual to employ formulæ which to the best of our knowledge give the molecular composition in the state of

Chemical change or chemical action consists of carbon, hydrogen, in the composition of molecules, of one atom of carbon, twice the action of agents such as heat, &c., but the determination of of two or more elements or compounds has a molecular weight

Three kinds of changes are to be observed, which therefore is changes which involve combination, acid. When chemical involve decomposition or separation, and molecular formulæ, not involve at the same time both decomposition and combination, but from Changes of the first and second kind, according to deduce the present views of the constitution of molecules, atoms occupy in of very rare occurrence; in fact, chemical action is almost always to involve the occurrence of a single appears kinds of change, for, as already pointed out, in both these assume that the molecules of hydrogen, oxygen, &c., we must several other elements are diatomic, or that they consist of two atoms. Indeed, it appears probable that they consist exceptions the elements are all compounds, and with few atoms united together by one or more units of oxygen of similar cording to their valencies. If this be the case, the affinity, as it is evident that there is no real distinction between, however, the reactions which take place when two elements combine together and when an element in a compound is displaced by another. The combination, as it is ordinarily termed, of chlorine with hydrogen, and the displacement, or displacement, of chlorine by the action of potassium iodide, may be cited as examples; if these reactions are represented, as they are commonly are, by equations which express the relative weights of the bodies which enter into reaction, and of the products, thus—

they appear to differ in character; but if they are represented by molecular equations, or equations which express the relative number of molecules which enter into reaction and which result from the reaction, it will be obvious that the character of the reaction is substantially the same in both cases, and that both are instances of the occurrence of what is ordinarily termed double displacement.

For chemical action to take place between two bodies it is necessary that they should be in contact, and, generally speaking, that one of them should be in the state of liquid or gas.

In all cases of chemical change energy in the form of heat is either developed or absorbed, and the amount of heat developed or absorbed in a given reaction is as definite as are the weights of the substance engaged in the reaction. Thus, in the production of hydrochloric acid from hydrogen and chlorine 22,000 units of heat are

¹ A unit of heat is the quantity of heat necessary to raise the temperature of 1 gramme of water 1° C., and whenever in this article it is

developed; in the production of hydrobromic acid from hydrogen and bromine, however, only 8440 units of heat are developed; and in the formation of hydriodic acid from hydrogen and iodine 6040 units of heat are absorbed.

This difference in behaviour of the three elements, chlorine, bromine, and iodine, which in many respects exhibit considerable resemblance, may be explained in the following manner. We may suppose that in the formation of gaseous hydrochloric acid from gaseous chlorine and hydrogen, according to the equation

a certain amount of energy is expended in separating the atoms of hydrogen in the hydrogen molecule, and the atoms of chlorine in the chlorine molecule, from each other; but that heat is developed by the combination of the hydrogen atoms with the chlorine atoms, and that, as more energy is developed by the union of the atoms of hydrogen and chlorine than is expended in separating the hydrogen atoms from each other and the chlorine atoms from one another, the result of the action of the two elements upon each other is the development of heat,—the amount finally developed in the reaction being the difference between that absorbed in decomposing the elementary molecules and that developed by the combination of the atoms of chlorine and hydrogen. In the formation of gaseous hydrobromic acid from liquid bromine and gaseous hydrogen—

in addition to the energy expended in decomposing the hydrogen and bromine molecules, energy is also expended in converting the liquid bromine into the gaseous condition, and probably less heat is developed by the combination of bromine and hydrogen than by the combination of chlorine and hydrogen, so that the amount of heat finally developed is much less than is developed in the formation of hydrochloric acid. Lastly, in the production of gaseous hydriodic acid from hydrogen and solid iodine—

so much energy is expended in the decomposition of the hydrogen and iodine molecules and in the conversion of the iodine into the gaseous condition, that the heat which it may be supposed is developed by the combination of the hydrogen and iodine atoms is insufficient to balance the expenditure, and the final result is therefore negative; hence it is necessary in forming hydriodic acid from its elements to apply heat continuously.

These compounds also afford examples of the fact that, generally speaking, those compounds are most readily formed, and are most stable, in the formation of which the most heat is developed. Thus, chlorine enters into reaction with hydrogen, and removes hydrogen from hydrogenized bodies, far more readily than bromine; and hydrochloric acid is a far more stable substance than hydrobromic acid, hydriodic acid being greatly inferior even to hydrobromic acid in stability.

When two substances which by their action upon each other develop much heat enter into reaction, the reaction is usually complete without the employment of an excess of either; for example, when a mixture of hydrogen and oxygen, in the proportions to form water—

is exploded, it is entirely converted into water. This is

stated that a certain amount of heat is developed in the production of a certain body, the production of a quantity of it equal to its molecular weight in grammes is to be understood. Thus, in the above case, the production of hydrochloric, hydrobromic, and hydriodic acids means the production respectively of 36.36, 81.75, and 127.53 grammes of these bodies.

also the case if two substances are brought together in solution, by the action of which upon each other a third body is formed which is insoluble in the solvent employed, and which also does not tend to react upon any of the substances present; for instance, when a solution of a chloride is added to a solution of a silver salt, insoluble silver chloride is precipitated, and almost the whole of the silver is removed from solution, even if the amount of the chloride employed be not in excess of that theoretically required.

But if there be no tendency to form an insoluble compound, or one which is not liable to react upon any of the other substances present, this is no longer the case. For example, when a solution of a per-salt of iron is added to a solution of potassium thiocyanate, a deep red coloration is produced, owing to the formation of thiocyanate of iron. Theoretically the reaction takes place in the case of the per-nitrate of iron in the manner represented by the equation

Ferric nitrate. Potassium thiocyanate. Ferric thiocyanate. Potassium nitrate.

but it is found that even when more than sixty times the amount of potassium thiocyanate required by this equation is added, a portion of the ferric nitrate still remains unconverted, doubtless owing to the occurrence of the reverse change—

In this, as in most other cases in which substances act upon one another under such circumstances that the resulting compounds are free to react, the extent to which the different kinds of action which may occur take place is dependent upon the mass of the substances present in the mixture. As another instance of this kind, the decomposition of bismuth chloride by water may be cited. If a very large quantity of water be added, the chloride is entirely decomposed in the manner represented by the equation—

Bismuth chloride

Bismuth oxychloride.

the oxychloride being precipitated; but if smaller quantities of water be added the decomposition is incomplete, and it is found that the extent to which decomposition takes place is proportional to the quantity of water employed, the decomposition being incomplete, except in presence of large quantities of water, because of the occurrence of the reverse action—

Chemical change which merely involves simple decomposition is also influenced by the presence of the products of decomposition. Thus when calcium carbonate is strongly heated in an open vessel, it is entirely decomposed into carbon dioxide gas and calcium oxide—

Calcium carbonate. Carbon dioxide. Calcium oxide.

When it is heated in a confined space, the decomposition only goes on until the liberated gas has attained a certain tension, and as long as the temperature does not vary, the tension remains the same, and is independent of the proportion of the compound decomposed, that is to say, of the amount of calcium oxide present; but the tension increases if the temperature is raised, and diminishes if it is lowered, owing to the recombination of a portion of the carbon dioxide with the calcium oxide; for example, at 800° C. the tension is equivalent to a column of mercury 85 millimetres high, but at 1040° C. it is equivalent to a column of 520 mm. Deville applies the term dissociation to changes which occur in this manner; the term only applies to those cases of decomposition in which products are obtained which under the conditions of the experiment are capable of reuniting to form the original sub-

stance. When such substances are heated in a confined space, not only does decomposition take place, but a certain proportion of the decomposition products recombine, and for each degree of temperature a definite relation exists between the number of molecules broken up and the number of molecules reconstituted; an equilibrium is thus maintained, and the tension remains constant. But as the temperature rises, a larger number of molecules are decomposed and a proportionally smaller number reformed than at the lower temperature, so that the tension rises with the temperature. When, however, a substance like calcium carbonate is heated in an open vessel, the carbon dioxide escapes as it is formed, and therefore it is impossible for recombination to occur, and ultimately the whole of the carbonate is decomposed. Apparently whenever solid substances undergo dissociation and furnish a solid and a gaseous product, the tension of dissociation is always independent of the amount of the solid decomposition product present.

The Elements and their Compounds.

The elements are usually divided into two great classes, the metallic and the non-metallic elements, the following being classed as non-metals, and the remainder as metals:—

Hydrogen.	Selenium.
Chlorine.	Tellurium.
Bromine.	Nitrogen.
Iodine.	Boron.
Fluorine.	Carbon.
Oxygen.	Silicon.
Sulphur.	Phosphorus.

The metals are mostly bodies of high specific gravity; they exhibit, when polished, a peculiar brilliancy or metallic lustre, and they are good conductors of heat and electricity; whereas the non-metals are mostly bodies of low specific gravity, and bad conductors of heat and electricity, and do not exhibit metallic lustre. The non-metallic elements are also sometimes termed metalloids, but this appellation, which signifies metal-like substances, strictly belongs to certain elements which do not possess the properties of the true metals although they more closely resemble them than the non-metals in many respects; thus, selenium and tellurium, which are closely allied to sulphur in their chemical properties, although bad conductors of heat and electricity, exhibit metallic lustre and have relatively high specific gravities.

But when the properties of the elements are carefully contrasted together it is obvious that no strict line of demarcation can be drawn dividing them into two classes; and if they are arranged in a series, those which are most closely allied in properties being placed next to each other, it is evident that there is a more or less regular alteration in properties from term to term in the series.

When binary compounds, or compounds of two elements, are decomposed by an electric current, the two elements make their appearance at opposite poles. Those elements which are disengaged at the negative pole are termed electro-positive, or positive, or basylous elements, whilst those disengaged at the positive pole are termed electro-negative, or negative, or chlorous elements. But the difference between these two classes of elements is one of degree only, and they gradually merge into each other; moreover the electric relations of elements are not absolute, but vary according to the state of combination in which they exist, so that it is just as impossible to divide the elements into two classes according to this property as it is to separate them into two distinct classes of metals and non-metals. The following, however, are negative towards the remaining elements which are more or less positive:—

Fluorine.	Oxygen.
Chlorine.	Sulphur.
Bromine.	Selenium.
Iodine.	Tellurium.

Elements which readily enter into reaction with each other, and which develop a large amount of heat on combination, are said to have a powerful affinity for each other. The tendency of positive elements to unite with positive elements, or of negative elements to unite with negative elements, is much less than that of positive elements to unite with negative elements, and the greater the difference in properties between two elements the more powerful is their affinity for each other. Thus, the affinity of hydrogen and oxygen for each other is extremely powerful, much heat being developed by the combination of these two elements; when binary compounds of oxygen are decomposed by the electric current, the oxygen invariably appears at the positive pole, being negative to all other elements, but the hydrogen of hydrogen compounds is always disengaged at the negative pole. Hydrogen and oxygen are, therefore, of very opposite natures, and this is well illustrated by the circumstance that oxygen combines, with very few exceptions, with all the remaining elements, whilst compounds of only a very limited number with hydrogen have been obtained.

Hydrides.—The only elements which are known to form binary compounds with hydrogen are fluorine, chlorine, bromine, iodine, oxygen, sulphur, selenium, tellurium, carbon, silicon, nitrogen, phosphorus, arsenic, antimony, and copper. Palladium has the property of absorbing a large volume of hydrogen gas, and it is supposed forms a definite compound with it; sodium and potassium, when heated to 350° to 400° C., also absorb hydrogen and appear to form definite compounds. With the exception of carbon, which furnishes an enormous number of compounds with hydrogen, the above-named elements unite with hydrogen only in one proportion, or at most in two or three different proportions. Excepting oxygen, fluorine, chlorine, and bromine, they do not readily enter into reaction with hydrogen, so that in most cases, in order to obtain their compounds with hydrogen, it is necessary to resort to indirect methods of preparation. The compounds of the elements with hydrogen may all be included under the general title of hydrides, but usually they possess specific names; thus, the hydride of oxygen is known as water, and the hydride of nitrogen as ammonia. Some of the hydrides of carbon are gases, but the majority are either liquids or solids; the two known hydrides of oxygen, water and the so-called peroxide of hydrogen, are liquids; a gaseous and a liquid hydride of sulphur are known; three hydrides of phosphorus are said to exist, one of which is liquid, one solid, and one gaseous; hydride of copper is a solid; and the hydrides of the remaining elements are gases. Excepting the hydride of copper, all are colourless substances. The following is a list of the known hydrides, including, however, only the first or simplest hydride of carbon:—

Name	Formula.	
Hydrogen hydride, or hydrogen.....	H ₂	gas.
fluoride, or hydrofluoric acid.....	HF	"
chloride, or hydrochloric acid.....	HCl	"
bromide, or		"
iodide, or		"
oxide, or water	H ₂ O	liquid.
dioxide.....	H ₂ O ₂	"
sulphide, or sulphuretted hydrogen.....	H ₂ S	gas.
persulphide.....	H ₂ S ₂ (?)	liquid.
Selenium hydride.....	H ₂ Se	gas

Oxides.—The element oxygen is known to form compounds with all the elements excepting fluorine, but the affinity of the various elements for oxygen, and consequently the stability of the compounds resulting from their union with oxygen, varies within very wide limits; the oxides of many elements which have but a weak affinity for oxygen can only be obtained by indirect means.

Although many of the elements unite with oxygen in several proportions, none are known to furnish more than five distinct oxides, and these belong to a certain limited number of forms, since they contain one, two, three, four, or five atoms of oxygen in the molecule. But as the same number of atoms of oxygen may unite with a given element in more than one proportion, each of these five classes includes sub-classes. The composition of the oxides may be best illustrated and their behaviour explained by regarding them as formed on the type of the two oxides of hydrogen, hydrogen monoxide or water, OH_2 , and hydrogen dioxide, O_2H_2 .

The *monoxides* are formed on the type of a single molecule of water, that is to say, they may be regarded as derived from a single molecule of water by the displacement of the two atoms of hydrogen by the equivalent amount of other elements. If two atoms of a monad element, or single atom of a dyad element, or of a polyad element which functions as a dyad, displace the two atoms of hydrogen, normal monoxides result, examples of which are potassium monoxide, K_2O , and copper oxide, Cu_2O . But monoxides are known in which two atoms of a dyad or it may be polyad element displace the two atoms of hydrogen in water; it is supposed that in this case the two atoms of polyad metal are united together and therefore function as a dyad compound radicle. Monoxides of this kind are usually termed suboxides; the suboxide of copper, $(\text{Cu}_2)'\text{O}$, and the suboxide of palladium, $(\text{Pd}_2)'\text{O}$, may be cited as examples. The supposed constitution of the three classes of monoxides is represented by the following graphic formulæ:—

Two classes of *dioxides* may be distinguished:—the one formed from two molecules of water by the displacement of the four atoms of hydrogen by a single tetrad atom, such as carbon dioxide, $\text{C}''\text{O}_2$, and tin dioxide, $\text{Sn}''\text{O}_2$; the other formed from a single molecule of hydrogen dioxide by the displacement of the two atoms of hydrogen either by two monad atoms, or by a single dyad atom, such as potassium dioxide, $\text{K}'_2\text{O}_2$, barium dioxide, $\text{Ba}''\text{O}_2$, and manganese dioxide, $\text{Mn}''\text{O}_2$. These two kinds of dioxide differ enormously in chemical properties; their supposed constitution is represented by the following graphic formulæ:—

The dioxides derived from hydrogen dioxide are usually termed peroxides.

The *trioxides* are divisible into three classes, but all may be regarded as derived from three molecules of water. In the one class the six atoms of hydrogen are displaced by a single hexad atom, as in sulphur trioxide, $\text{S}'''\text{O}_3$, and tungsten trioxide, $\text{W}'''\text{O}_3$; in the second class the six atoms of hydrogen are displaced by two polyad (tetrad?) elements, which together function as a hexad compound radicle, as in ferric oxide, $(\text{Fe}_2)'''\text{O}_3$, and chromic oxide,

$(\text{Cr}_2)'''\text{O}_3$. A third class may be regarded as formed by the displacement of the six atoms of hydrogen by two triad atoms, and includes boron trioxide, $\text{B}'''\text{O}_3$, and bismuth trioxide, $\text{Bi}'''\text{O}_3$. There are considerable differences in properties between these three classes of trioxides; their graphic formulæ are as follows:—

As examples of *tetroxides*, osmium tetroxide, OsO_4 , antimony tetroxide, Sb_2O_4 , the so-called magnetic oxide of iron, Fe_3O_4 , and lead tetroxide, Pb_3O_4 , may be quoted. These oxides undoubtedly belong to different classes, but too little is known of them for their relations to each other to be defined.

Lastly, the few *pentoxides* which are known may, with scarcely an exception, be regarded as derived from five molecules of water, the ten atoms of hydrogen being displaced by two pentad atoms. This is illustrated by the following graphic formulæ of phosphorus and arsenic pentoxides:—

Several of the oxides of chlorine and of nitrogen, and one of the oxides of sulphur, are gases; the oxides of hydrogen, and the oxides of chlorine and of nitrogen which are not gaseous, are liquid; and the remaining oxides are solid bodies.

Acids—Bases—Salts.—Many oxides have an extremely powerful affinity for water, and readily combine with it; but the compounds formed in this manner by different oxides differ remarkably in properties. For example, when sulphur trioxide, SO_3 , is added to water, a solution is obtained which has the property of changing the colour of blue vegetable colouring matters, such as litmus, to red, and possesses a sharp sour taste; but when the oxide of a highly positive metal, such as barium oxide, is added to water, a solution capable of restoring the blue colour to reddened litmus is obtained. In both cases the water combines with the oxide, the sulphur trioxide being converted into *sulphuric acid*:—

and the barium oxide into *barium hydroxide*:—

Sulphuric acid and barium hydroxide are representatives of two most important classes of compounds, the *acids* and *bases*; the oxides which furnish acids when combined with water are conveniently termed *acid oxides*, whilst those which furnish bases may be termed *basic oxides*.

The acid oxides, however, unite with the basic oxides to form a third class of compounds called *salts*, which are usually neutral bodies, that is to say, they have no action either on red or on blue litmus; thus, sulphur trioxide and barium oxide unite to form the salt barium sulphate:—

The term acid is applied by some chemists to what are here called acid oxides, and what we have called basic oxides are frequently spoken of as bases, the acids being regarded as salts of hydrogen; this view of the constitution of acids is adopted because they are formed by the union of oxides of negative elements with the oxide of the positive element hydrogen, just as what are ordinarily

terned salts are formed by the union of oxides of negative with oxides of positive elements. In this article, however, the term acid is restricted to compounds containing hydrogen.

The acids formed from the oxides of the various elements in the manner above explained all enter into reaction with bases, and with especial readiness with those derived from the highly positive elements, in such a manner that salts are produced, the hydrogen of the acid being displaced by the metal of the base, and water formed; for example,

Sulphuric acid. Barium hydroxide. Barium sulphate.

We may therefore define an acid to be a compound containing one or more atoms of hydrogen which may be displaced by a metal by the action of a base; but, as will be evident later on, although applicable to all acids, this definition is of rather too wide a character.

The hydrides of fluorine, chlorine, bromine, and iodine also readily enter into reaction with bases, exchanging their hydrogen for other elements; and as they also possess an acid taste and redden blue litmus, they are universally regarded as acids. The fact that these compounds are powerful acids is of considerable importance, as showing that it is the association of hydrogen with a negative radicle which renders it subject to displacement by positive elements—that is to say, a compound in which hydrogen is associated with a negative radicle will have the properties of an acid, and the more negative the radicle the more readily can the hydrogen be displaced. The composition of all known acids is entirely in accordance with this view; thus, in nitric acid a single atom of hydrogen is associated with the negative compound radicle NO_3 , in sulphuric acid two atoms of hydrogen are combined with the negative compound radicle SO_4 , and in phosphoric acid three atoms of hydrogen are associated with the negative compound radicle PO_4 .

The oxides of the most negative and most positive elements most readily combine with water to form acids or bases, whilst the oxides of the feebly negative or feebly positive elements either do not unite with water or form extremely unstable combinations. Similarly, the oxides of the most negative and most positive elements unite together to form stable salts, much heat being developed by their combination, whereas the oxides of feebly negative and feebly positive elements either do not unite or form very unstable salts. The several oxides of an element often differ remarkably in properties, however, one oxide exhibiting acid characters, whilst another has basic properties.

The oxides of most of the so-called metallic elements are acted upon by acids, such as sulphuric, nitric, and hydrochloric acids, a salt of the metal being formed in all cases in which corresponding salts exist, and the hydrogen of the acid being eliminated in combination with the oxygen of the oxide as water; for example:—

Manganese oxide. Sulphuric acid. Manganese sulphate. Water.

If corresponding salts do not exist, however, and action take place, then other products are obtained. Thus, no stable sulphate corresponding with manganese dioxide exists, and when this body is decomposed with sulphuric acid oxygen is evolved:—

Manganese Sulphuric Manganese Water. Oxygen.
oxide. acid. sulphate.

Actions of this kind invariably occur with the oxides which may be regarded as formed on the type of hydrogen dioxide.

Sulphides.—Sulphur enters into union with most of the

elements forming compounds analogous to the oxides in composition and general properties; in fact, we may distinguish acid and basic sulphides, corresponding to the acid and basic oxides, and salts formed by the union of these two classes of sulphides. With very few exceptions the sulphides are solid bodies. Selenium and tellurium, which are closely allied to sulphur, also form compounds with many elements more or less closely resembling the sulphides, but they are of little importance.

Chlorides—Bromides—Iodides—Fluorides.—With very few exceptions compounds of all the elements with chlorine have been obtained, and, especially from a theoretical point of view, the chlorides are a class of bodies of the highest importance. The affinity of bromine and iodine for other elements being much lower than that of chlorine, and their compounds much less stable than the corresponding chlorides, comparatively few bromides and iodides are known. Fluorides of many of the elements have also been obtained.

Chlorine unites with many of the elements in two or more proportions, but at most six atoms of chlorine unite with a single atom of another element. The majority of the chlorides are either liquids or solid bodies which may be more or less readily volatilized.

Nitrides—Phosphides.—Nitrogen has but a slight affinity for other elements; its most important compounds are ammonia, NH_3 , cyanogen, C_2N_2 , and the oxides of nitrogen. The only elements which combine with it readily are tantalum, titanium, tungsten, and vanadium, and most of its compounds can be prepared only by indirect methods.

Phosphorus readily combines with chlorine, bromine, iodine, oxygen, and sulphur, and with most of the metals; its compounds with the non-metallic elements are of considerable importance to the chemist; but its compounds with the metals have been little studied.

Scarcely any of the remaining elements form compounds of importance with elements other than those which have already been considered.

We now proceed to the description of the elements and their more important compounds, commencing with hydrogen, and then passing to the so-called non-metallic elements, which will be considered in the following order:—Hydrogen, oxygen, chlorine, bromine, iodine, fluorine, sulphur, selenium, tellurium, nitrogen, phosphorus, boron, carbon, and silicon; after which the remaining elements will be briefly described as much as possible in the order of their relationship to each other. Hydrogen is placed at the head of the list, because it is the unit or standard of comparison both for the atomic weights and valencies of the remaining elements, and it is now usual also to refer the densities in the state of gas of all compounds to hydrogen. On account of the number and variety of their compounds with other elements the non-metallic elements are by far the most important, and therefore are naturally considered before the metals.

HYDROGEN.

Symbol, H; Atomic wt., 1; Molecular wt., 2; Valency, 1.

This element was discovered by Cavendish in 1766, and was called by him *inflammable air*; the name of Hydrogen is derived from *ὑδρ*, water, and *γεννάω*, to generate, on account of its forming water when burnt. It occurs in the free state in the gases of volcanoes, and by the aid of the spectroscope has been detected in the sun, stars, and nebulae; it chiefly exists in combination with oxygen as water, and is an important constituent of all vegetable and animal substances.

Hydrogen is obtained by the decomposition of water in

various ways. Thus, when two platinum plates, connected with the poles of a voltaic battery, are plunged into water acidulated with a few drops of sulphuric acid, hydrogen is evolved from the plate in connection with the negative pole, oxygen being disengaged from the positive pole. Water is also resolved into its elements when its vapour is heated by passing through an intensely ignited platinum tube, or by discharging electric sparks in an atmosphere of steam; but under these circumstances, owing to the recombination of much of the hydrogen and oxygen, only a small quantity of the mixed gases is obtained.

Hydrogen may also be obtained from water by the action of the highly positive metals, cesium, rubidium, potassium, sodium, and lithium, at ordinary temperatures; in each case a solution of the metallic hydroxide is obtained, and hydrogen evolved, thus:—

Barium, strontium, and calcium also decompose water in the cold, and hydrogen is evolved when magnesium is heated with water at temperatures below the boiling point of the latter. Many other metals, such as iron, manganese, zinc, cadmium, cobalt, nickel, tin, and antimony evolve hydrogen from water when its vapour is passed over the metal heated to redness, the oxide of the metal being formed, thus:—

Aluminium also decomposes water at a red heat, but owing to the formation of an impermeable coating of aluminium oxide on the surface of the metal the action soon stops. Metals like copper, mercury, silver, gold, and platinum are without action even at a bright red heat. Many metals, however, which do not decompose water unless heated with it, if placed in contact with a more negative element cause the evolution of hydrogen at ordinary atmospheric temperatures; for example, if a plate of zinc, coated with spongy copper by immersion in a solution of copper sulphate, be placed in water, hydrogen is gradually evolved, the reaction which occurs being as follows:—

Hydrogen is usually prepared by the action of zinc or iron on a solution of hydrochloric or sulphuric acid. The change which occurs is represented in the following equations:—

All metals which readily decompose water when heated readily furnish hydrogen on treatment with hydrochloric and sulphuric acid, and many other metals enter more or less readily (although none so readily) into reaction with these acids; also many other acids may be used in place of hydrochloric or sulphuric acid, but none act more readily. In all cases the action consists in the displacement of the hydrogen of the acid by the metal employed, and if the acid is not one which can enter into reaction with the displaced hydrogen, the latter is evolved as gas. If pure hydrogen is required, it is necessary to employ pure zinc or iron; the impurities in the ordinary metal communicate an extremely disagreeable odour to the gas.

On the large scale nearly pure hydrogen may be prepared by passing steam over charcoal or coke heated to dull redness. If the temperature be kept sufficiently low, hydrogen and carbon dioxide are the sole products:—

and the latter may be removed by causing the gas to traverse a vessel filled with slaked lime; but if the temperature be allowed to rise too high carbon monoxide is also produced, and cannot be removed from the mixture.

Pure hydrogen is a colourless, transparent, odourless and tasteless gas. It has never been liquefied, and is very slightly soluble in water, 100 volumes of water dissolving 1.93 volumes of the gas at all temperatures between 0° and 24° C. It is the lightest of all known bodies, its specific gravity being .0693, that of air being unity; one litre of hydrogen at 0° C, and under the pressure of 760 mm. of mercury, weighs .0896 gramme, and it is important to remember this number, since the weight of a litre of any other gas may be at once found by multiplying .0896 by half the molecular weight of the gas, the specific gravity of a gas referred to hydrogen being always half its molecular weight (p. 471).

Pure hydrogen is not poisonous, though it cannot support life; and if mixed with a certain proportion of oxygen, it may be breathed for some time without inconvenience. It is extremely inflammable, and burns in the air with a colourless non-luminous flame forming water; a burning taper is extinguished when plunged into hydrogen, and all bodies which burn in the air are incapable of burning in hydrogen.

Hydrogen does not spontaneously enter into reaction with any of the elements, although it has a powerful affinity for several of them. Thus, when hydrogen and oxygen are mixed nothing occurs, but if a burning taper or a heated wire is applied, a violent explosion ensues, water being produced. Similarly, chlorine and hydrogen are without action upon each other in the dark, but if the mixture is exposed to a bright light or is heated by the passage of an electric spark, the gases at once combine with explosive violence, forming hydrochloric acid. It has already been pointed out that we must suppose that the molecules which constitute free hydrogen, chlorine, and oxygen gases are diatomic, and that hydrogen and chlorine, for example, do not directly combine to form hydrochloric acid, but that an action occurs such as is represented by the equation—

and that, therefore, the combination of the atoms of chlorine and hydrogen is preceded by the separation of the two atoms of chlorine in the chlorine molecules, and of the two atoms of hydrogen in the hydrogen molecules, from each other, which necessarily involves an expenditure of energy. The application of heat, we may assume, serves to effect this decomposition of some of the molecules of hydrogen, oxygen, and chlorine into their constituent atoms, and since much heat is evolved by the subsequent combination of the atoms of hydrogen and chlorine, or of hydrogen and oxygen, it is only necessary to apply heat to start the reaction, because the remaining molecules are decomposed by the heat developed in the formation of the first portions of water or hydrochloric acid.

Compounds of hydrogen with bromine, iodine, sulphur, and nitrogen may also be obtained directly from these elements and hydrogen, although only with difficulty and in small quantity.

OXYGEN.

Symbol, O; Atomic wt., 15.96; Molecular wt., 31.92; Valency, ".

Oxygen was first isolated by Priestley in 1774; its name is derived from *ὀξύς*, sour, and *γεννάω*, to generate, in allusion to the circumstance that many of the bodies formed by combining it with other elements dissolve in water, producing sour or acid solutions. It was long believed, in fact, that oxygen was a constituent of all acids.

Oxygen is the most abundant and the most important of all the elements. About one-fifth of the atmosphere consists of free oxygen; it is the chief constituent by weight of water; it is an important constituent of all animal and vegetable substances, and is contained in greater or less proportion in most mineral substances.

Oxygen may be obtained from water in the manner already mentioned under hydrogen, by decomposing it by an electric current, and also by transmitting chlorine gas and steam through a porcelain tube heated to bright redness—

the oxygen is freed from hydrochloric acid and any excess of chlorine by passing it through a solution of sodium hydroxide.

The most interesting method of obtaining oxygen, although it is not a usual method of preparing it, is that by which it was first isolated by Priestley. When mercury is heated in contact with air to a temperature just below its boiling point, it gradually becomes covered with a red scale of mercuric oxide, HgO , and when this red scale is exposed to a considerably higher temperature it is broken up into oxygen and metallic mercury.

The oxides of gold, platinum, and other metals which have but a slight affinity for oxygen, are very readily decomposed when heated, oxygen being evolved and the metal remaining. Many other metallic oxides, and especially those which may be regarded as formed on the type of hydrogen dioxide, which readily breaks up into water and oxygen, when more or less strongly heated, are resolved into oxygen and a lower oxide:—lead dioxide, PbO_2 , barium dioxide, BaO_2 , and manganese dioxide, MnO_2 , for example. In the case of manganese dioxide, 3MnO_2 give Mn_3O_4 , the decomposition taking place at a red heat. Barium dioxide when strongly heated gives up one-half of its oxygen to produce barium monoxide, $2\text{BaO}_2 = \text{O}_2 + 2\text{BaO}$; and by passing moist air over less heated barium monoxide it may be reconverted into the dioxide, which may be decomposed by a stronger heat. By repetitions of these processes it is possible to procure large quantities of oxygen with the aid of a small quantity of barium dioxide, and it has been proposed to employ this method for the preparation of oxygen on the large scale, but in practice there have been found difficulties attending its use.

Ordinarily when pure oxygen is required it is prepared by heating potassium chlorate, which ultimately furnishes potassium chloride and oxygen: $2\text{KClO}_3 = 3\text{O}_2 + 2\text{KCl}$. This decomposition requires a high temperature, and can only be effected in vessels of *hard* glass, but when the chlorate is mixed with about one-eighth of its weight of a metallic oxide, such as copper oxide, ferric oxide, or manganese dioxide, the oxygen is given off at a considerably lower temperature, and with great rapidity; in this case, however, it is impure, being always contaminated with small quantities of chlorine.

When potassium chlorate is heated alone the salt fuses, but after a considerable evolution of oxygen has taken place the fused mass becomes pasty, and on examination it is found to consist of a mixture of potassium chloride and potassium perchlorate, KClO_4 , so that the first stage in the decomposition may be represented by the equation—

the potassium perchlorate is resolved on further heating into oxygen and potassium chloride. When a metallic oxide is mixed with the chloride, however, and heat applied, the latter does not fuse, and the formation of potassium perchlorate cannot be detected at any stage of the decomposition.

It is difficult to explain the manner in which the metallic oxide acts in promoting the decomposition of the chlorate, since it is found to be unchanged at the conclusion of the reaction; but it is a well-known fact that many bodies which, under ordinary circumstances, do not yield oxygen, readily part with this element when another substance having a tendency to combine or enter into reaction with oxygen is introduced into the sphere of action. Thus, when potassium dichromate is heated with concentrated sulphuric acid, oxygen is evolved, the yellow solution becoming green owing to the formation of chromium sulphate—

But if the dichromate is dissolved in a considerable quantity of water no change of this kind takes place even after prolonged heating; when, however, a body like sulphurous acid, H_2SO_3 , which has a tendency to unite with oxygen to form sulphuric acid, is added to the solution, it at once becomes green,—the dichromate being decomposed as represented in the above equation, and the oxygen being fixed by the sulphurous acid. Hence it is not improbable that the metallic oxide acts in virtue of a tendency to form a higher oxide, which higher oxide is no sooner produced, however, than it is broken up into oxygen and the lower oxide. The lower oxide may again undergo conversion into the higher oxide and the latter be broken up into oxygen and lower oxide, so that a relatively small quantity of the metallic oxide may suffice to promote the decomposition of a relatively large quantity of chlorate.

When a small quantity of cobalt sesquioxide, or a few drops of a solution of a cobalt salt, is added to a clear concentrated aqueous solution of bleaching powder, which is then gently heated, oxygen is evolved with great regularity, and the bleaching powder is completely resolved into oxygen and calcium chloride—

The bleaching powder solution is not decomposed in this manner when heated alone, and there is no doubt that the cobalt oxide induces the decomposition by acting as a carrier of oxygen; that is to say, it first takes oxygen away and passes to a higher state of oxidation, and then gives it up again, the higher oxide being an extremely unstable body.

When silver oxide is added to a solution of hydrogen dioxide in water, metallic silver, water, and oxygen are produced—

This reaction is especially interesting, as it affords experimental evidence in favour of the assumption that the molecule of oxygen consists of two atoms; moreover, a very considerable quantity of heat is developed in the reaction, and since there is every reason for believing that the separation of an atom of oxygen from silver oxide, and of an atom of oxygen from hydrogen dioxide, are both operations which involve an expenditure of energy, there can be little doubt that the heat developed is due to the combination of the atoms of oxygen to form molecules. In other words, this reaction affords evidence that oxygen atoms have a powerful affinity for each other.

The green leaves of plants with the aid of sunlight are enabled to decompose water and carbon dioxide, and evolve oxygen from them.

No method has yet been devised of directly separating pure oxygen from air, but Graham has shown that it is possible to obtain an "air" containing about 41.6 per cent. by volume of oxygen instead of about 20.8 per cent., which is the amount present in ordinary air, by *dialyzing* air through india-rubber. For this purpose a bag composed of the thinnest india-rubber supported on cloth is connected with a Sprengel air-pump; if the pump is kept in action, after the air is exhausted from the bag, it is found that it continues slowly to deliver "air" which, however, is richer in oxygen than ordinary air in about the proportions above-mentioned. The gases do not pass through actual pores, but apparently they are dissolved by the rubber, which is thus *wetted through* by the liquefied gases, and evaporate into the vacuum on the other side of the membrane, the increased amount of oxygen being doubtless due to the greater solubility of oxygen in rubber.

Many other methods of obtaining oxygen are known, but the above given are sufficient to illustrate the nature of the changes by which it is produced.

Oxygen is a colourless, odourless, and tasteless gas, which has hitherto resisted all attempts to liquefy it; it is only slightly soluble in water, 100 volumes of which at ordinary atmospheric temperatures dissolve about three volumes of oxygen. All bodies which burn in the air burn with greatly increased brilliancy and rapidity in oxygen; thus, a glowing splinter of wood bursts into flame when plunged into oxygen, and burns with great brilliancy; and even iron, if heated to redness before it is introduced into the gas, readily burns in it. In all cases in which bodies burn in oxygen the substances burnt combine with the oxygen to form new substances, and the heat and light developed are a consequence of their union. The weight of the products corresponds exactly with the weight of the body burned *plus* the weight of the oxygen consumed. The combination of two or more bodies when thus accompanied by the development of heat and light is termed combustion, the body burnt being the combustible, and the body in which the burning takes place the supporter of combustion. Thus, hydrogen is a combustible since it burns in oxygen, but oxygen is a supporter of combustion. These terms are merely relative, however, since oxygen may just as readily be burnt in hydrogen as hydrogen in oxygen; and, similarly, air may be burnt in coal gas.

The combination of oxygen with other elements is termed oxidation. In all cases of oxidation heat is developed, but it depends entirely upon the rapidity with which the oxidation is effected whether light is also produced, that is to say, whether what is ordinarily termed combustion takes place. Thus, when iron is burnt in oxygen, the combination of the two elements is effected with great rapidity, and a large amount of heat is developed within a very short space of time, and hence the product of combustion is intensely heated and becomes incandescent; when, however, iron slowly oxidizes or rusts, no light is produced, although actually more heat is developed than when the same weight of iron is burnt in oxygen, the oxide Fe_3O_4 being formed in the latter and the oxide Fe_2O_3 in the former case.

The various elements enter into reaction with oxygen with very various degrees of readiness, but as in the case of hydrogen and oxygen it is mostly necessary at least to start the reaction by the application of heat; and if the combination of the two elements can give rise to the development of only a moderate amount of heat, it is usually necessary to continue the application of heat until the oxidation is complete. Phosphorus slowly absorbs oxygen, but the remaining non-metallic elements are not affected

by it at ordinary temperatures. The highly positive metals readily absorb it; the majority of the metals, however, when in the massive state are unacted upon in dry oxygen, but undergo oxidation more or less readily in moist oxygen or air. The coating of oxide first formed frequently protects the metal from more than a superficial oxidation. Some of the metals when in a state of very fine division, for instance, lead as obtained by the ignition of its tartrate, undergo oxidation so readily, however, that spontaneous combustion results from their mere exposure to air or oxygen. The spontaneous combustion of substances such as woollen refuse, greasy tow, and hay is a precisely similar phenomenon,—the heat developed by their slow oxidation being to a great extent retained, as they are bad conductors of heat, until finally it becomes sufficient to inflame them. Most animal and vegetable substances when exposed to the air decay, and it is generally supposed that they simply undergo slow oxidation. Pasteur has shown, however, that the oxidizing power of atmospheric oxygen is much exaggerated, and that the decay of animal and vegetable substances exposed to air is not simply the result of the action of the atmospheric oxygen, but of the action of oxygen assisted by microscopic organisms, the decay taking place at an extremely slow and almost imperceptible rate when these organisms are entirely excluded.

When the colourless gas nitric oxide is mixed with oxygen, red fumes of higher oxides of nitrogen are formed, and by this reaction oxygen may with facility be detected and distinguished from other gases. A solution of potassium hydroxide and pyrogallol, or pyrogallie acid, or an ammoniacal solution of cuprous chloride, absorbs oxygen with avidity and may be employed to remove it from a mixture of gases

Ozone.

Symbol, O_3 ; Molecular wt., 47.83.

When exposed to the action of electricity, and especially under the influence of what is termed the silent discharge, oxygen undergoes a contraction of volume and acquires remarkably different properties, its chemical activity being greatly enhanced. It has been shown that the change consists in the conversion of the oxygen into an allotropic modification which has received the name of ozone ($\delta\zeta\omega$) in allusion to its peculiar odour; and from Sir Benjamin Brodie's experiments (*R. Soc. Trans.*, 1872, p. 435) there can be no doubt that ozone differs from ordinary oxygen merely in that its molecule contains three atoms; this difference is expressed in the following graphic formulæ:—

Various forms of apparatus are employed in ozonizing oxygen, but all are constructed on the principle of the Siemens's induction tube. This consists of two wide tubes of nearly equal diameter placed one within the other and coated on their exterior surfaces with tinfoil; the coatings of tinfoil are connected with the terminals of a powerful induction coil, and a current of oxygen is passed through the narrow space between the two tubes, and is thus submitted to the action of the electric discharge. In the apparatus employed by Brodie the coatings of tinfoil are dispensed with, but the inner tube is filled with water in which is placed one of the terminal wires of the induction coil, and the outer tube is immersed in a vessel of water in connection with the other terminal wire of the coil.

It is essential that the oxygen submitted to the electric action be pure and in a very dry condition; and it is especially desirable to prevent the elevation of temperature

consequent on the electric action, which may be done by placing fragments of ice in the interior of the tube and also in the water contained in the external cylinder in which the induction tube is immersed.

But it is not possible in this manner to convert more than about 15 per cent. of the oxygen into ozone, and Brodie's experiments prove that there is a fixed limit prescribed by the conditions of experiment, beyond which the formation of ozone cannot pass. The explanation of this appears to be that the formation of ozone belongs to the class of actions termed dissociation phenomena; that is to say, not only is oxygen converted into ozone by the electrical action, but ozone is also reconverted into oxygen, the amount of ozone actually obtained under given conditions of experiment being dependent upon the extent to which these two opposite kinds of change take place. We may therefore expect that the amount of oxygen finally obtained in the form of ozone will be greater the less the ozone is exposed to the electric action; and that this is actually the case is proved by the fact that no advantage is gained by submitting the oxygen more than once to the electric action or by passing it slowly through the induction tube, and also by the behaviour of carbon dioxide. When this gas is submitted to the action of the electric discharge, it is partially resolved into carbon monoxide and oxygen, and the latter is in part transformed into ozone. Brodie has shown that it is not difficult, by passing a rapid current of carbon dioxide through the induction tube, to convert 75 per cent. of the oxygen eliminated from the carbon dioxide into ozone, and has even succeeded in converting as much as 85 per cent.

Pure ozone has never yet been obtained, however. Ozone is also formed in small quantity when water is decomposed by the electric current, employing plates of platinum or gold as electrodes; the amount produced is greater the smaller the electrodes. The slow oxidation of phosphorus in moist air is said to be attended with the production of small quantities of ozone, and it is probable that ozone is formed in other slow oxidations; it appears that in all such cases the formation of ozone is accompanied by that of hydrogen dioxide, a fact which is also true of electrolytic ozone.

Traces of ozone are usually present in the atmosphere, especially in the open country; and it no doubt plays an important part in the removal of organic impurities from the atmosphere.

Ozone is a colourless gas of peculiar unpleasant odour; 100 volumes of water at 0° C. only absorb about 5 volume, so that it is considerably less soluble than oxygen. Air charged with ozone exerts an irritating action upon the respiratory organs. Ozone is chiefly remarkable, however, on account of its oxidizing power. Thus, dry mercury, which is not in the least affected by ordinary oxygen, unless heated to near its boiling point, is at once oxidized by ozone, and dry iodine absorbs ozone and is oxidized by it. It bleaches a solution of indigo, which is oxidized by it. It also rapidly corrodes organic substances, such as cork and caoutchouc, which therefore cannot be employed in experiments with ozone. Paraffin, however, is not attacked by it, and an excellent air-tight joint between two glass tubes may be made by means of it. A piece of glass tube, into which they exactly fit, is slipped over the two tubes, which are placed close together, and a fragment of pure paraffin is placed at the external junction of the tubes; on gently heating the paraffin it melts, and the liquid being extremely limpid runs into and fills up the narrow space between the tubes.

In the conversion of oxygen into ozone the volume contracts by one-third, three molecules of oxygen furnishing two molecules of ozone.

but when ozone is reconverted into oxygen the volume increases to the same extent that it diminishes when oxygen is converted into ozone, since

The conversion of ozone into oxygen may be effected by heat. Thus, when ozonized oxygen is passed through a glass tube heated to 110° C. slight decomposition of the ozone takes place; at 200° C. the decomposition is very rapid, about 97 per cent. being converted into oxygen; and below 300° C. decomposition is complete.

Similarly, ozone is decomposed to an unlimited extent by contact with metallic silver, and by manganese dioxide, lead dioxide, and copper oxide, without the substances undergoing more than an excessively minute increase of weight in the reaction. These decompositions afford instances of recurrent action, the active substance being alternately oxidized and reduced by the ozone; in the case of silver, supposing silver monoxide is formed, although the oxide produced is probably a higher oxide, the reaction may be represented in the following manner:—

Many reactions are known which prove that ozone has this power of effecting deoxidation, although itself a most powerful oxidizing agent; thus, by its action on a solution of sodium dioxide, sodium monoxide and oxygen are obtained:—

The decomposition of ozone in this manner by silver, &c., is accompanied by the development of a considerable amount of heat; thus, according to Berthelot, no less than 29,600 units of heat are evolved in the reaction

A corresponding amount of energy must therefore be expended in the formation of ozone from ordinary oxygen. But the conversion of ozone into ordinary oxygen is to be regarded as occurring in two stages,—in the first the molecule is resolved into $\text{O}_2 + \text{O}$, and in the second two atoms of oxygen from two molecules of ozone unite forming a molecule of ordinary oxygen. The splitting up of the ozone molecule into $\text{O}_2 + \text{O}$ probably requires an expenditure of energy, so that the energy developed in the reaction in the form of heat is due to the combination of the atoms of oxygen to form molecules, but is less than that actually developed by their combination by the amount expended in the decomposition of the ozone molecules. As already pointed out, the fact that so large an amount of heat is developed by the combination of oxygen with oxygen indicates that the affinity of the oxygen atoms for each other is very considerable. This being the case, we are enabled also to understand how it is that ozone has such superior power as an oxidizing agent as compared with ordinary oxygen, for it is evident that, in reactions into which oxygen enters, for every 32 grammes employed an amount of energy corresponding to at least 29,600 heat units must be expended in order to separate the two atoms forming the oxygen molecules from each other; whereas, mostly, when ozone is employed, the amount of energy to be expended is only that required to effect the decomposition of the ozone molecules into $\text{O}_2 + \text{O}$, which is probably very small.

The amount of oxidation effected by the same amount of ozone varies, however, according to the nature of the body

oxidized, and Brodie's experiments show that four classes of oxidations may be effected by ozone:—

In the first class of reactions one-third of the molecule is active in effecting oxidation, the remaining two-thirds being obtained as oxygen, so that the volume of oxygen obtained is the same as the volume of ozone operated upon. If the number of atoms of oxygen active in effecting oxidation are placed within brackets, this class of oxidations is expressed by the equation—

The action of ozone on a solution of sodium dioxide, quoted above, and its action on a solution of potassium iodide—

on ferrous chloride and sulphate, on an acid solution of potassium ferrocyanide, and on sodium arsenite, are special cases of this class of oxidations.

In the second class of reactions, four atoms of oxygen from two molecules of ozone are active, the remaining two atoms being obtained as oxygen; or

The oxidation of strongly alkaline solutions of sodium hyposulphite, the oxidation of hydriodic acid, and the oxidation of barium pentasulphide are included in this class.

In a third class of reactions, ten atoms of oxygen from four molecules of ozone are active in promoting oxidation, a single molecule of oxygen being obtained; or

The oxidation of sodium sulphhydrate and of hydriodic acid at 0°C. are to be referred to this class.

Lastly, in a fourth class of reactions, the entire molecule is active in effecting oxidation; or

Examples of this class are afforded by the oxidation of tin dichloride, oil of turpentine, and neutral and slightly alkaline solutions of sodium hyposulphite.

That ozone can thus enter into reaction in so many different ways affords the most conclusive evidence of its compound nature, and by these reactions it may be distinguished from all known gases, and estimated.

The reaction with potassium iodide is usually employed for the detection of ozone, the liberation of iodine being rendered evident by the addition of starch paste, which with iodine furnishes a beautiful blue colour. The liberation of iodine from potassium iodide is not alone sufficient proof, however, of the presence of ozone. By comparing at different times the depth of colour produced on exposing slips of paper moistened with starch paste and potassium iodide solution to the air, for the same length of time, an estimate of the relative amounts of ozone present may be obtained.

Compounds of Hydrogen with Oxygen.

Water.

Symbol, OH_2 ; Molecular wt., 17.96.

Hydrogen and oxygen when mixed do not enter into reaction at the ordinary temperature; but the contact of flame or of any other red-hot body, the passage of the electric spark, and the contact of platinum cause reaction to take place with explosion. The flame and the electric spark act by their intense heat, and the nature of the influence which, perhaps, heat exercises in inducing the combination of hydrogen and oxygen has already been pointed out; but the action of platinum is more obscure. Spongy platinum and the fine powder of that metal called

platinum black, although cold, cause the mixed gases to explode as readily as flame docs. Even polished slips of platinum, if perfectly clean, will cause the reaction to take place, although more slowly. It appears that at first the absorption of the gases on the surface of the cold metal, and the consequent approximation of their particles, is sufficient to induce the combination of a part of the gases; this being accompanied by the development of heat, the metal becomes warmed and acts more vigorously, and the combination of further quantities of the gases takes place, by which more heat is developed, so that by degrees the metal becomes red-hot, and if any of the mixed gases be still uncombined it causes them to explode. In the case of the powder or the sponge, especially the former, all this takes place so rapidly from the enormous surface of the metal, that it becomes red-hot as soon as it is introduced, and fires the mixture as rapidly as a flame. Now, it is well known that metallic platinum, and especially spongy platinum, or platinum black, readily condenses gases upon its surface; but the condensation is attended by the development of heat, and it seems not improbable, therefore, that its action in causing the combination of hydrogen with oxygen is of the same character as the action of flame,—that the platinum, in fact, does not itself induce the combination, but that the heat resulting from the condensation of the gases by the platinum is the direct cause of the reaction. Graham's researches have shown also that heated platinum absorbs hydrogen, and the absorption is doubtless accompanied by the development of heat; this is an additional reason for the action of platinum becoming more vigorous as it becomes warmer.

A series of experiments by Von Meyer (*Journal für praktische Chemie*, 1876, p. 121) may here be referred to, as illustrating in a remarkable manner the influence of finely-divided platinum in causing the combination of gases. It was first shown by Bunsen that when a mixture of hydrogen and carbon monoxide is exploded with insufficient oxygen to convert these two gases respectively into water and carbon dioxide, whatever the proportions employed, the quantities oxidized are always in a simple molecular ratio. From Von Meyer's experiments it appears that, when a similar mixture is placed in contact with finely-divided platinum, although the oxidation is effected very slowly, the same law obtains. Whereas, however, when the mixture of the three gases is exploded, always relatively more hydrogen than carbon monoxide is oxidized, the proportion in which the two gases are burnt being on the average about as 3 to 1, the reverse is the case when their oxidation is slowly effected with the aid of platinum; in the latter case the number of molecules of carbon monoxide oxidized to the dioxide is from 7 to 8 times as great as the number of hydrogen atoms oxidized to water.

When oxygen and hydrogen, from whatever cause, enter into reaction, it is always in the proportions to form water,—that is, invariably in the proportion of 2 volumes of hydrogen gas to 1 volume of oxygen gas. Any excess of either is left uncombined. If the water which is formed be measured as steam or gas, and its volume compared with the volume of the mixed gases at the same temperature before combination, it is found that condensation has taken place, 2 volumes of water gas being obtained from 2 volumes of hydrogen and 1 volume of oxygen gas; hence—

In the liquid state, however, the volume of the water formed is so small as compared with the volume occupied by the mixed gases that it may be neglected, so that if the contraction in volume which occurs on explosion is measured at the ordinary temperature, two-thirds of the

contraction represents the hydrogen, and one-third the oxygen, which has disappeared. This enables us to use hydrogen to determine the amount of free oxygen in air, or in any gaseous mixture, one-third of the contraction which occurs when a measured quantity of the gas is exploded with a measured excess of hydrogen representing the amount of oxygen present.

The affinity of oxygen for hydrogen, as measured by the heat developed by their combination, is very great, 68,376 units of heat, according to Thomsen, being evolved in the combination of 16 grammes of oxygen with 2.005 grammes of hydrogen, the product being liquid water at 18° C. By burning the two gases together from a jet the most intense artificial heat that is known, except that of the discharge of a powerful galvanic battery, is produced.

It is well here to call attention to the circumstance that the equations ordinarily employed to express the formation of water from its elements, and *vice versa* the resolution of water into its elements, viz.—

and

do not take into account that in the one case a large amount of heat is developed, and that in the other case a corresponding amount of energy is expended. These equations merely represent, in fact, the distribution of weight in the changes, and therefore are but imperfect expressions of what really occurs, since the development of heat in the formation of water, and the absorption of heat, or the expenditure of a corresponding amount of some other form of energy in its decomposition, are integral parts of the changes, the amount of heat developed or absorbed, under given conditions, being as definite and constant as the weights of the substances which enter into reaction and are produced. The same may be said of all equations employed to represent chemical change.

The composition of water may be determined by burning a known weight of hydrogen in an excess of oxygen, and weighing the water produced; then the difference between the weight of the hydrogen burnt and of the water produced is the amount of oxygen combined with the hydrogen. Or hydrogen is passed over a weighed quantity of copper oxide in a tube heated to redness; the hydrogen then *reduces* the oxide or removes the oxygen from it, forming water, which is carefully collected and weighed, and the loss of weight which the tube of copper oxide suffers is carefully determined. The loss of weight of the copper oxide gives the amount of oxygen, and the difference between this and the amount of water produced is the amount of hydrogen combined with this amount of oxygen.

The amount of oxygen combined with 2 parts by weight, or 2 atoms, of hydrogen is usually stated to be 16 parts, and 16 is generally regarded as the atomic weight of oxygen. But from the examination of the determinations which have been made by various elements of the composition of water, Staas, to whom we are indebted for the most exact determinations of atomic weights yet made, arrives at the conclusion that this number is too high, and that the atomic weight of oxygen is certainly not higher than 15.96. Thomsen has recently determined the amount of water produced by burning 2 litres of hydrogen in an excess of oxygen, and taking Regnault's numbers for the specific gravities of oxygen and hydrogen, he obtains a number for the atomic weight of oxygen which is in complete accordance with that given by Staas.

At the ordinary temperature of the air water is a clear, transparent, tasteless, and odourless liquid; it appears colourless when seen in small quantity, but that it really

has a pale blue colour is apparent when a shining white object is viewed through a column several feet in thickness.

Water is solid at temperatures below 0° C., 0° C. being the temperature at which frozen water or ice melts; the melting point is diminished by increase of pressure to the slight extent of 0.00757° C. for each additional atmosphere. Water expands in freezing, its density compared with water at 0° C. being .92. The conversion of liquid water at 0° C. into solid water or ice is accompanied by the liberation of heat, and heat is rendered latent or absorbed to the same extent in the melting of ice,—the quantity of heat absorbed or liberated in the melting of ice or freezing of water being sufficient to raise the temperature of 79 times its weight of water from 0° to 1° C.

Water evaporates at all temperatures when in contact with atmospheric air or other gases, and the vapour given off has a density and tension determined by the temperature; the tension of the vapour rapidly rises with the temperature, until at 100° C. it is equal to the ordinary atmospheric pressure (760 mm.), and the water boils. The boiling point, however, rapidly rises with increase of pressure, and sinks when the pressure is diminished; thus under the pressure of two atmospheres water boils at 121° C., and under the pressure of twelve atmospheres at 190° C. When water boils under the ordinary atmospheric temperature it is converted into 1600 times its volume of vapour. The conversion into vapour is attended with the absorption of a large amount of heat,—the quantity of heat absorbed or rendered latent in the conversion of water at 100° C. into steam of the same temperature being sufficient to raise the temperature of 536 times the weight of water converted into steam from 0° to 1° C.

Water, chemically speaking, is a remarkably neutral substance, and hence its great value to the chemist as a solvent. There are very few substances which are not to some extent dissolved by it, but the solubility of different substances is very unequal. Heat generally increases its solvent power, whilst cold diminishes it; there are many exceptions to this rule, however. The dissolution of substances which may again be separated from the solution undecomposed is accompanied, in the majority of cases, with an absorption of heat, as will be evident on inspection of the table on p. 185. In the first column the name of the substance is given, and in the second its formula; the third exhibits the number of molecules of water (in grammes) in which one molecule (in grammes) of the substance is dissolved at about 18° C.; the fourth column shows the number of units of heat developed or absorbed, the — sign indicating that heat is absorbed, and the + sign that it is developed.

It is extremely difficult to interpret the meaning of numbers such as are contained in the table, especially as we are almost entirely ignorant of the condition of substances in solution in water. But there is no doubt that the heat developed or absorbed on dissolving a solid substance is the net result of several distinct operations, which partly, perhaps, involve an absorption, and partly a development of heat. Thus, in the first place, there is a change of state from the solid to the liquid, which in most if not all cases involves an expenditure of energy; then, many substances on dissolving in water combine with it, the combination probably being always attended with development of heat. Contraction also generally takes place in the dissolution of salts in water, and is accompanied by a considerable development of heat, arising from the great resistance which water offers to compression. Chemists, moreover, are inclined to the belief that very many if not all substances, even those which are ordinarily regarded as stable in presence of water, enter to a greater or less extent into reaction with water when dissolved in it; a solu-

tion of sodium chloride, for example, may be regarded as containing a certain amount of sodium hydroxide and hydrochloric acid formed by the reaction—

Table of Phenomena attending Solution of Salts in Water.

Name.	Formula.	No. of mols. of water taken.	No. of units of heat developed or absorbed per molecule.
1. Crystalline Chlorine, Bromine, and Iodine compounds.			
Lithium chloride	LiCl	200	+ 8,440
Sodium chloride	NaCl	200	- 1,180
Potassium chloride	KCl	200	- 4,440
		100	- 4,410
Sodium bromide	NaBr	200	- 150
Potassium bromide	KBr	200	- 5,080
Sodium iodide	NaI	200	+ 1,220
Potassium iodide	KI	200	- 5,110
Magnesium chloride	MgCl ₂	800	+ 35,920
Aluminium chloride	Al ₂ Cl ₃	700	+ 153,690
2. Nitrates.			
Sodium nitrate	NaNO ₃	200	- 5,060
Potassium nitrate	KNO ₃	200	- 8,520
Silver nitrate	AgNO ₃	200	- 5,440
Thallium nitrate	TlNO ₃	300	- 9,970
Barium nitrate	Ba(NO ₃) ₂	400	- 9,400
Strontium nitrate	Sr(NO ₃) ₂	400	- 4,620
Lead nitrate	Pb(NO ₃) ₂	400	- 7,600
3. Sulphates.			
Sodium sulphate	Na ₂ SO ₄ + 10H ₂ O	Na ₂ SO ₄	400 - 60
			50 - 17,460
			100 - 18,130
			200 - 18,550
			400 - 18,760
		600	- 18,810
Potassium sulphate	K ₂ SO ₄	400	- 6,380
Magnesium sulphate	MgSO ₄ + 7H ₂ O	400	- 3,910
Zinc sulphate	ZnSO ₄ + 7H ₂ O	400	- 4,240
Iron sulphate	FeSO ₄ + 7H ₂ O	400	- 4,510
Nickel sulphate	NiSO ₄ + 7H ₂ O	800	- 4,250
Cobalt sulphate	CoSO ₄ + 7H ₂ O	800	- 3,570

The occurrence of reactions of this kind would in many cases involve an absorption, but in others a development of heat. The only two substances mentioned in the above table which develop heat to any extent when dissolved in water, it will be seen, are magnesium and aluminium chlorides. Both of these, however, are known to form compounds with water, and both probably enter to a very considerable extent into reaction with it in the manner above pointed out. It is even probable that the latter cannot exist as such when dissolved in water; the development of so large an amount of heat is therefore readily understood. But at present we are unable satisfactorily to account for the difference observed between salts such as potassium and sodium iodides, which so closely resemble each other in most respects, one of which, it will be noticed, absorbs 5110 units, whilst the other develops 1220 units of heat when dissolved in water.

From this it will be obvious that the study of the condition of salts in solution is beset with difficulties; the thermochemical method of investigation appears in most cases to be the only one which is applicable, since the introduction of new substances at once introduces a new set of conditions, but on account of the complexity of the phenomena attending dissolution, even the results obtained by this method possess only a limited value, and at present only general conclusions can be drawn from them.

Water, as we have already stated, enters into combination with oxides of many of the elements, forming two classes of compounds,—the acids, and the metallic

hydroxides or hydrates. The general properties and relations of these two classes of compounds may with advantage now be discussed.

The monoxides of the highly positive monad elements cesium, rubidium, potassium, sodium, and lithium form with water easily soluble hydroxides, which cannot be decomposed by heat; their solutions are soapy to the touch, and restore the blue colour to vegetable infusions which have been reddened by an acid. These hydroxides are usually termed alkalis,—a solution which has the power of restoring the blue colour to reddened litmus being said to exhibit an alkaline reaction. The term *alkali* is of Arabic origin, and was at first given to the crude sodium carbonate obtained from the ashes of sea-weed, a solution of which is soapy to the touch and restores the blue colour to reddened litmus, and like the above-mentioned hydroxides also has powerful cleansing properties.

The hydroxides derived from the monoxides of barium, strontium, and calcium, which are less positive elements, also exhibit an alkaline reaction, but they are not nearly so soluble in water; and, with the exception of barium hydroxide, they are decomposed on ignition, yielding the oxide and water. None of the remaining positive elements, except thallium, furnish soluble hydroxides which exhibit an alkaline reaction.

Similar differences may be observed between the oxides of negative elements, which furnish acids when combined with water. Thus, the monoxide of the highly negative element chlorine readily dissolves in water, but the acid produced is exceedingly unstable; similarly, the acids derived from the oxides of nitrogen are soluble, but of low stability. The oxides of the less negative elements, sulphur and phosphorus, however, furnish very soluble acids, which exhibit considerable stability, being with difficulty resolved into the oxide and water.

The lower oxides of the most positive elements enter into combination with water in such proportions as to produce compounds containing an equal number of atoms of hydrogen and oxygen; for example, sodium monoxide and water furnish sodium hydroxide—

and barium oxide and water yield barium hydroxide—

Hence these hydroxides may be looked upon as combinations of the respective elements with the monad compound radicle (OH) or hydroxyl; and the various compounds obtained from the oxides of the remaining elements by the action of water may either be regarded as similarly constituted, or may be viewed as combinations of one or more OH groups with compound radicles formed by the union of the elements with oxygen. Thus, we may regard nitric acid, HNO₃, as a compound of the two monad radicles, (NO₂) and (OH); sulphuric acid, H₂SO₄, as a combination of the dyad radicle (SO₂) with two OH groups; and phosphoric acid, H₃PO₄, as a combination of the triad radicle (PO) with three monad hydroxyl groups.

The number of OH groups which may be associated with a single atom of a given simple radicle or element, or with a compound radicle, entirely depends upon the nature of the radicle, but does not appear ever to exceed four; the stability of the compound also varies with the radicle, the tendency to form stable compounds with OH being the greater the more positive the radicle. In the case of compounds of feebly positive radicles with several OH groups, there is always a tendency for the elements of one or more molecules of water to separate from the compound, thus producing a body which is to be regarded as

a combination of one or more OH groups with an oxygenated radicle. For instance, ferric hydroxide, $\text{Fe}_2(\text{OH})_6$, very readily loses water, forming compounds such as $\text{Fe}_2\text{O}(\text{OH})_4$ and $\text{Fe}_2\text{O}_2(\text{OH})_2$.

Nearly all the bodies produced by the action of water on the oxides of the non-metals are to be regarded as compounds of oxygenated radicles with hydroxyl, and are more or less acid in character. As a rule, the more negative the radicle with which OH is associated the more powerful will be the acid, and since the addition of oxygen to the radicle renders it more negative, the acid furnished by the higher oxide of an element is usually more stable, and also a more powerful acid, than that furnished by the lower oxide; thus, sulphurous acid, H_2SO_3 , is extremely unstable as compared with sulphuric acid, H_2SO_4 , and a much less powerful acid, but the former may be regarded as a combination of the dyad radicle (SO), and the latter as a combination of the dyad radicle (SO_2), with twice the monad radicle (OH). The behaviour of the positive elements is exactly complementary of this, since the greater the amount of the negative element oxygen associated with them the less is the tendency to furnish corresponding hydroxides when combined with water, and the less the stability of the resulting hydroxides; and, as a rule, also the basic properties both of the oxides and of the hydroxides corresponding to them become much less pronounced as the relative proportion of oxygen increases.

In all cases in which oxides unite with water to produce stable combinations, much heat is developed; the stability of the compounds formed by the combination of water with oxides, in fact, appears to be directly in proportion to the amount of heat developed in their formation, and it has been shown that the formation of many of the most unstable hydroxides from their elements would be accompanied by an absorption of heat; hence their instability is readily understood.

When the hydroxides are added in sufficient quantity to solutions of the acids, mostly neutral solutions are produced,—that is to say, solutions which do not affect either blue or red litmus. The acid is then said to be neutralized by the hydroxide, or *vice versa*. The basic oxides which furnish hydroxides, and indeed the basic oxides generally, behave in a similar manner with acids. In these cases a *salt* is produced; thus, by the addition of sodium hydroxide to sulphuric acid the salt sodium sulphate is obtained—

Obviously, we may regard the salts produced in this manner as formed by the displacement of the hydrogen of the acid by more or less positive elements or simple radicles, and they may actually in many cases be prepared by the action of the metals on the acids; for example—

They are also obtained, as we have seen, by the union of a more or less basic with a more or less acid oxide. But a large number of salts are known derived from the acids by the displacement of hydrogen by compound radicles; thus, many of the salts of the element vanadium are formed by the introduction of the group $(\text{V}_2\text{O}_5)^{\text{IV}}$, which functions as a tetrad element, in place of the hydrogen of acids, vanadyl sulphate being $(\text{V}_2\text{O}_5)^{\text{IV}}(\text{SO}_4)_2$. The ammonium salts are formed in a similar manner by the displacement of hydrogen in acids by the monad compound radicle $(\text{N}^+\text{H}_4)^-$. But the hydrogen of many hydroxides may also be displaced by positive elements or radicles; for example, zinc hydroxide, although insoluble in water, dissolves in solutions of the alkalis, and on heating metallic zinc with a concen-

trated solution of potassium hydroxide, it dissolves with evolution of hydrogen—

Zinc hydroxide and similar compounds, therefore, display both basic and acid functions; and it is difficult to deny the compounds formed from them by introducing positive elements in place of hydrogen the title of salts.

Another class of oxy-salts are formed by the union of two different oxides of the same element; the compounds of fluorine, chlorine, bromine, and iodine with positive elements, and of acid with basic sulphides, are also termed salts, the compounds of sulphur being distinguished as sulpho-salts or thio-salts, whilst those of the four other elements are distinguished as haloid salts.

From this it will be obvious that the term *salt* is of very wide application, and that it is almost impossible to define it in a few words. It is also extremely difficult strictly to define an acid, for, although the very greatest difference is observable between the compounds of the oxides of highly negative and of highly positive elements with water, the differences become less and less marked as we pass from one end of the series to the other. The only definition which really separates bodies which are usually regarded as true acids from hydroxides possessing acid properties is afforded by the fact that, whilst the hydrogen in all hydroxides which exhibit basic properties may be displaced by negative and also in some instances by positive radicles, the hydrogen in acids can only be displaced by positive radicles. For example, the hydrogen in zinc hydroxide may be displaced by the positive radicle potassium and by the negative radicle NO_2 , but it is only possible to displace the hydrogen in sulphuric acid by positive radicles. This definition is not applicable, however, to organic acids.

The extent to which hydrogen may be displaced in an acid by positive radicles is termed its *basicity*, an acid which contains a single atom of displaceable hydrogen being termed monobasic, and acids containing two or three atoms of displaceable hydrogen, dibasic or tribasic. On the other hand, the hydroxides and basic oxides are frequently spoken of as monacid, diacid, or triacid, &c., according as they are capable of neutralizing a single molecule, two, or three molecules of a monobasic acid; thus, sodium hydroxide is monacid since a single molecule neutralizes a single molecule of monobasic nitric acid, forming the salt sodium nitrate—

and barium hydroxide is a diacid base since it neutralizes two molecules of nitric acid—

But we may also regard the salts formed by the action of acids on hydroxides as derived from the latter by the displacement of hydrogen by negative compound radicles,—sodium nitrate, for example, as sodium hydroxide in which the atom of hydrogen has been displaced by the monad compound radicle NO_2 ; hence we may define the acidity of hydroxides to be the extent to which hydrogen may be displaced in them by negative radicles.

In polybasic acids, that is to say, in acids containing two or more atoms of displaceable hydrogen, it is possible to displace the hydrogen step by step; thus, by the addition of a single molecule of sodium hydroxide to a single molecule of sulphuric acid, only one-half the hydrogen in the acid is displaced—

but by the addition of a second molecule of the hydroxide the second atom of hydrogen is also displaced—

Salts derived from acids by the partial displacement of their hydrogen are termed *acid salts*, those in which the hydrogen displaceable by metals is entirely displaced being termed *normal salts*. Similarly, when the hydrogen in polyacid hydroxides is entirely displaced by negative radicles, normal salts are obtained, but when it is only partially displaced the so-called *basic salts* are produced, which bear precisely the same relation to the hydroxides that the acid salts bear to the acids. Thus, from the triacid hydroxide, bismuth hydroxide, $\text{Bi}'''(\text{OH})_3$, and the monobasic acid, nitric acid, we obtain normal bismuth nitrate and two basic bismuth nitrates:—

These salts are strictly comparable with the normal and two acid salts produced from the tribasic acid, phosphoric acid, and the monacid hydroxide, sodium hydroxide:—

Two explanations may be given of the constitution of the salts formed by displacing the hydrogen in polybasic acids by polyad elements; the formula of barium sulphate, for example, may be represented by either of the following formulæ:—

according as it is supposed that two atoms of hydrogen in a single molecule of the acid are displaced, or that two molecules of the acid are concerned in the formation of the salt, one atom of hydrogen in each being displaced by each of the barium atoms. There is not at present sufficient evidence to enable us to decide definitively in favour of one or the other of these views, but the great tendency which the polybasic acids exhibit to form double salts appears to render the latter the more probable.

The formation of salts by the action of acids on metallic oxides and hydroxides is in all cases attended with a development of heat. This subject has been very carefully studied by several chemists, especially by Thomsen, whose results for a number of acids are given in the following tables. The amount of heat developed in the reaction—

that is to say, on adding a solution of α molecules (in grammes) of sodium hydroxide to a solution of one molecule (in grammes) of the acid, represented by Q,—is given for a number of acids in the first of the following tables. The second table exhibits the amount of heat developed in the reaction—

i.e., on adding a solution of one molecule of sodium hydroxide to a solution of α molecules of the acid Q. Each molecule (in grammes) of sodium hydroxide was dissolved in 200 molecules (in grammes) of water, and the solutions of the acids were of equivalent strength; that is to say, the number of grammes of acid required to form a normal salt with $23 + 16 + 1$ or 40 grammes of sodium hydroxide were dissolved in 18×200 or 3600 grammes of water. The temperature at which the two solutions were mixed in all the experiments was about 18°C . The results are expressed in hundreds of heat-units, and according to Thomsen they may all be relied on within 1 per cent.

Silicic.....	$\frac{1}{2}$ (H ₄ . SiO ₄)	2,710

From these tables it will be evident—(1), that when a molecule of sodium hydroxide in aqueous solution enters into reaction with an acid, the heat developed is very nearly proportional to the quantity of acid present until this amounts to 1, $\frac{1}{2}$, $\frac{1}{3}$, or $\frac{1}{4}$ molecule, according as the acid is mono-, di-, tri-, or tetrabasic; but that when the amount of acid added exceeds that requisite to form the normal salt, the different acids behave differently, heat being in some cases developed, and in others absorbed, according to the constitution of the acid; and (2), that mostly when a molecule of an acid in aqueous solution enters into reaction with sodium hydroxide, the amount of heat developed increases almost in proportion to the amount of the latter, and until 1, 2, 3, or 4 molecules are added, according as the acid is mono-, di-, tri-, or tetrabasic; the further addition of sodium hydroxide is not then attended with any considerable development of heat.

Very different amounts of heat, it will be observed, are developed on neutralizing the different acids, but there is mostly a remarkable similarity in the results obtained in the case of acids which from chemical evidence are known to be closely allied. Thus, hydrochloric, hydrobromic, and hydriodic acids exhibit the same heat of neutralization; and the numbers for sulphuric and selenic acids, and for phosphoric and arsenic acids, are very similar. Hydrofluoric acid, it will be seen, differs considerably from the allied monobasic acids since the addition of the first half molecule of sodium hydroxide produces less heat than the second, which is not improbably owing to the formation of

the acid salt HF₂Na; it differs also by its high heat of neutralization.

The tables show also that the dibasic acids may be divided into several groups, according to the amounts of heat developed on the addition of the first and second molecules of sodium hydroxide. The first group includes hydrofluosilicic and hydrochloroplatinic acids, the amount of heat developed by the second molecule of hydroxide being equal to that developed on the addition of the first molecule. The second group includes sulphuric, selenic, oxalic, and tartaric acids; with these acids less heat is developed by the first than by the second molecule; thus:—

Sodium hydroxide.	Sulphuric acid.	Selenic acid.	Oxalic acid.	Tartaric acid.
1st Molecule.	146	148	138	124
2d „	164	156	145	129

In the third group, which includes sulphurous, selenious, carbonic, and boric acids, and probably also chromic, phosphorous, and succinic acids, the contrary is the case:—

Sodium hydroxide.	Sulphurous acid.	Selenious acid.	Carbonic acid.	Boric acid.
1st Molecule.....	159	148	110	111
2d „	131	122	92	89

The tribasic acids exhibit similar differences; thus:—

Sodium hydroxide.	Citric acid.	Arsenic acid.	Phosphoric acid
1st Molecule.....	124	150	148
2d „	126	126	123
3d „	132	83	69

These differences which acids of the same basicity exhibit when submitted to thermochemical investigation correspond to differences in their chemical behaviour. For example, when a solution of citric acid is neutralized with sodium carbonate and evaporated to crystallization, the trisodium salt Na₃C₆H₅O₇ is readily obtained, but when a solution of phosphoric or arsenic acid is similarly treated, the disodium salt Na₂HPO₄ or Na₂HAsO₄ is formed; the trisodium salts of these acids can only be procured by adding sodium hydroxide. Apparently the trisodium salts of phosphoric and arsenic acids are partially decomposed by water, as their solutions are strongly alkaline; hence the third molecule of hydroxide does not effect the complete conversion of the di- into the tri-sodium salt. The behaviour of sulphuric acid will be discussed later on.

All soluble hydroxides when in solution appear to have nearly the same heat of neutralization, as will be seen from the following table, which exhibits the number of units of heat developed on neutralizing solutions of equivalent quantities of various hydroxides with a solution of one molecule (in grammes) of sulphuric acid, or of the equivalent quantities (2 molecules) of hydrochloric or nitric acid at 18° C.:—

Name of hydroxide.	Sulphuric acid.	Hydrochloric acid.	Nitric acid.
Lithium hydroxide	31,290	27,700	...
Sodium „	31,330	27,490	27,350
Potassium „	31,290	27,560	27,540
Thallium „	31,130	27,520	27,350
Barium „	27,780	28,260
Strontium „	30,710	27,630	...
Calcium „	31,140	27,900	...

But very different amounts of heat are developed on dissolving the hydroxides which are insoluble in water in acids. The following numbers represent the heat of

neutralization of various hydroxides insoluble in water by a molecule of sulphuric acid —

Magnesium hydroxide.....	31,220
Manganese „	26,480
Nickel „	26,110
Cobalt „	24,670
Iron „	24,920
Cadmium „	23,820
Zinc „	23,410
Copper „	18,440

Thomsen, however, considers that the differences between the amounts of heat developed when these hydroxides are dissolved in acids, and when soluble hydroxides are neutralized, are due to the heat absorbed in rendering them soluble; or in other words, that solutions of these hydroxides would have the same heat of neutralization as solutions of soluble hydroxides.

One of the most interesting results of the thermochemical investigation of the behaviour of acids with metallic hydroxides is the proof that when sodium hydroxide, for example, is added to a mixture of two acids in insufficient quantity to neutralize both, the sodium salts of the two acids are seldom formed in the proportions in which the two acids are mixed. Thus, when a solution of 2 molecules of sodium hydroxide is mixed with a solution containing two molecules of monobasic nitric acid and one molecule of dibasic sulphuric acid, two-thirds of the sodium hydroxide enter into reaction with the nitric acid and one-third with the sulphuric acid. The avidity, as it is termed by Thomsen, of nitric acid to enter into reaction with sodium hydroxide is thus twice as great as that of sulphuric acid. The avidity of hydrochloric acid for sodium hydroxide is equal to that of nitric acid, but the avidities of hydrobromic, hydriodic, and hydrofluoric acids are less than that of hydrochloric acid in the proportion $\text{HCl} : \text{HBr} : \text{HI} : \text{HF} = 100 : 89 : 79 : 5$.

In concluding this brief account of the thermochemical behaviour of some of the acids and hydroxides, we may observe that the interpretation of most of the remarkable results to which we have alluded has not been given. The study of this branch of chemistry is yet in its infancy, and is beset with difficulties, but its importance can scarcely be exaggerated. At present we scarcely know more than that in the formation of a given substance a certain amount of heat is finally developed or absorbed, but in most cases we are ignorant of the value of one or more of the several distinct operations which we believe are involved in the reaction by which it is produced, so that the results given by different substances cannot as a rule be satisfactorily compared.

Many substances belonging to all classes of chemical compounds unite with water, forming combinations from which it may be again expelled by the application of a greater or less degree of heat, and from the circumstance that many of these combinations are crystalline, the water is said to be present in the form of *water of crystallization*. Thus, potassium hydroxide crystallizes with 2 molecules of water, as $\text{KHO} + 2\text{H}_2\text{O}$; copper sulphate with 5 molecules, as $\text{CuSO}_4 + 5\text{H}_2\text{O}$; and sodium sulphate with 7 and with 10 molecules. The water may usually be expelled from these compounds by the application of a gentle heat, and many salts part with their water of crystallization on exposure to the air; but others are not deprived of it, or more than a part, unless very strongly heated. Copper sulphate, for example, readily loses 4 of the 5 molecules of water with which it combines, but the remaining molecule is only expelled by heating to about 200°C .; 5 of the 7 molecules of water in crystallized magnesium sulphate are readily removed, and the sixth is expelled at about 150°C ., but the seventh is retained at 200°C .

The compounds containing water of crystallization are usually denied the title of *atomic* compounds ordinarily applied to combinations of two or more elements in which it is supposed the constituent atoms are all associated in a single molecule under the influence of the force which has received the name of chemical affinity, and in contradistinction are termed *molecular* compounds, being regarded as combinations of two or more separate molecules. This, although perhaps true of many of the compounds containing water of crystallization, is certainly not true of all, and notably of the sulphates which are only deprived of their water by heating to high temperatures.

Hydrogen Dioxide, $\text{H}_2\text{O}_2 = 33.92$.

This compound cannot be obtained directly from its elements, but there appears to be little doubt that it may be formed by the combination of oxygen with water, since it is produced in many cases of slow oxidation in presence of water, and particularly in processes where ozone is formed. It is produced in small quantity when water is decomposed by an electric current, especially when small electrodes are employed. Its formation in this manner may be regarded as an oxidation of water, but it has been suggested that it is the direct product of electrolysis, and that the oxygen evolved is a secondary product derived from the decomposition of the hydrogen dioxide; thus—

It is usually prepared from barium dioxide by double decomposition with hydrochloric or carbonic acid:—

Hydrogen dioxide or peroxide is an exceedingly unstable substance, and readily decomposes even in aqueous solution into water and oxygen, especially on heating. The solution is more stable if slightly acid. A dilute solution may be concentrated by evaporation in vacuo over sulphuric acid, and hydrogen dioxide was obtained in this manner by its discoverer Thénard as a colourless transparent liquid, of specific gravity 1.452, which did not freeze at -30°C .; it is doubtful, however, whether it has ever been prepared quite free from water. It did not redden litmus, but had a harsh bitter taste; when placed upon the hand it instantly turned the cuticle white.

Hydrogen dioxide exhibits the closest resemblance to ozone. Thus, it is decomposed by mere contact with finely-divided metals, such as silver, gold, and platinum, with evolution of oxygen. Like ozone it is a powerful reducing agent, entering into reaction with silver oxide, for example, to form water, oxygen, and metallic silver:—

According to Fairley, about 37,000 units of heat are developed in the production of 32 grammes of oxygen by this reaction, which thus affords further proof of the strength of the affinity of oxygen for oxygen, as probably the heat developed is chiefly, if not entirely, due to the combination of the oxygen atoms. Many other oxides are reduced by it, either to the metallic state or to lower oxides, oxygen being evolved and water produced.

But hydrogen dioxide is also a powerful oxidizing agent. Thus, it decolorizes a solution of indigo; it converts sulphurous acid, H_2SO_3 , into sulphuric acid, H_2SO_4 ; lead sulphide, PbS , into lead sulphate, PbSO_4 ; and many oxides into higher oxides. It decomposes a solution of hydriodic acid with separation of iodine:—

With the aid of this reaction an important series of experiments to ascertain the connection between the con-

ditions of a chemical change and its amount have been made by Harcourt and Esson. The experiments consisted in adding successive equal portions of sodium hyposulphite to a solution containing hydrogen dioxide, hydriodic acid, and a little starch. By this reagent the iodine which is continually being liberated by the action of the dioxide on the hydriodic acid is instantly reconverted into iodide, so that the liquid, though it contain starch, and though iodine is being formed in it, remains quite colourless as long as any hyposulphite is present. But when the last trace of hyposulphite has been removed by the action of the iodine, the portion of iodine next formed remains free, and the liquid becomes suddenly blue. The addition of another small portion of hyposulphite again removes the colour, and until all the hyposulphite is decomposed the solution remains colourless, and then again becomes suddenly blue. The intervals at which the blue colour appeared were carefully noted, and the amount of hydrogen dioxide decomposed being known from the amount of hyposulphite employed, the quantity of dioxide decomposed in a given time was thus determined. The observed results are given in the following table:—

Amount of Dioxide.	Time from the beginning in minutes.	Chemical change in each interval.	Interval in minutes.
20.95	0.00		
19.95	4.57	1	4.57
18.95	9.37	1	4.80
17.95	14.5	1	5.13
16.95	19.37	1	5.37
15.95	25.57	1	5.70
14.95	31.63	1	6.11
13.95	38.20	1	6.52
12.95	45.23	1	7.03
11.95	52.82	1	7.59
10.95	61.12	1	8.39
9.95	70.15	1	9.03
8.95	80.03	1	9.93
7.95	91.27	1	11.19
6.95	103.83	1	12.61
5.95	118.50	1	14.62
4.95	135.65	1	17.35
3.95	157.00	1	21.15
2.95	181.53	1	27.53
1.95	223.45	1	33.92
.95	291.13	1	66.73

The general conclusion deducible from these experiments is, that the amount of change at any moment varies directly with the amount of dioxide present in the solution; in accordance with this law, the quantities of dioxide at the end of a series of times taken in arithmetical progression are themselves in geometrical progression. This law of chemical action has been corroborated by the investigation of other reactions, and it is probably of very general application.

When hydrogen dioxide solution is mixed with a concentrated solution of barium hydroxide, crystalline hydrated barium dioxide, $\text{BaO}_2 \cdot 6\text{H}_2\text{O}$, separates—

In a similar manner, peroxides of many metals are precipitated on the addition of their salts to a solution of hydrogen dioxide.

Hydrogen dioxide, it will be evident, differs remarkably from hydrogen monoxide or water. Its instability, and its tendency to enter into reaction with other bodies with separation of oxygen, appear to be explained by the fact that its decomposition into water and oxygen is attended with the development of a very considerable amount of heat. The behaviour of ozone and hydrogen dioxide, in fact, strikingly illustrates one of the most important laws of chemical action, viz. that those decompositions and

reactions which are attended with the development of heat always take place more readily than those which require an absorption of heat, and they take place the more readily the greater the amount of heat which is liberated. The heat developed by the decomposition of ozone and hydrogen dioxide, we have seen, is to be traced to the same cause, being due, it can scarcely be doubted, to the combination of the oxygen atoms.

FLUORINE—CHLORINE—BROMINE—IODINE

Fluorine,	Symbol, F;	Atomic wt., 19.1;	Molecular wt., (F) ₂
Chlorine,	" Cl;	" 35.36;	" 70.72
Bromine,	" Br;	" 79.75;	" 159.50
Iodine,	" I;	" 126.53;	" 253.07

These four elements form with metals compounds analogous to sea-salt, and from this circumstance the name halogens, or salt-producers (from $\alpha\lambda\gamma\sigma$, sea-salt), has been applied to them, their compounds with other radicles being frequently termed haloid compounds. They are always classed together on account of their close analogy in properties, but there are numerous and very important distinctions between them.

The element fluorine is not known in the free state, all attempts to isolate it having failed on account of the impossibility of obtaining vessels which can withstand its action. Chlorine is a gas of a greenish yellow colour, whilst bromine, at ordinary atmospheric temperatures, is a mobile red liquid, so deep in colour as to be almost opaque, and iodine is a black, crystalline, and very brittle solid, which exhibits metallic lustre.

None of these elements are ever met with in the free state, but their compounds are very widely distributed, and they are to be detected in most rocks and soils, in spring and sea-water, and in the ashes of plants and animals. Fluorine occurs most abundantly in combination with calcium as fluor-spar, and chlorine in combination with sodium as ordinary salt, large deposits of which exist in various parts of the globe; considerable deposits of bromine in combination with potassium have within recent years been discovered in Stassfurt, but no abundant source of iodine has hitherto been discovered.

Chlorine was discovered by Scheele in 1774, and was so named on account of its colour (from $\chi\lambda\omega\rho\acute{o}\varsigma$, green), but its elementary nature was first established by Davy in 1810. Bromine was first described in 1826 by Balard, who obtained it from *bittern*, the mother liquor of sea-water, after the less soluble salts have been extracted by evaporation and crystallization; it was named on account of its irritating odour (from $\beta\rho\acute{o}\mu\omicron\varsigma$, a stench). Iodine was discovered by Courtois in 1811, in the waste liquors from the manufacture of sodium carbonate from the ashes of sea-weed; it received its name from the beautiful violet colour of its vapour ($\iota\omega\epsilon\iota\delta\acute{\iota}\varsigma$, violet-coloured).

Chlorine is usually prepared, both in the laboratory and on the large scale, by gently heating a concentrated solution of hydrochloric acid with manganese dioxide; the reaction appears to take place in two stages,—the first consisting in the formation of the manganese chloride corresponding to manganese dioxide—

but this compound is so unstable that it breaks up into chlorine and a lower chloride of manganese—

It may be procured directly from salt by acting on a mixture of salt and manganese dioxide with sulphuric

acid, but in this case hydrochloric acid is first produced by the action of the sulphuric acid on the salt—

The hydrochloric acid then enters into reaction with the manganese dioxide, as explained above, but the manganese dichloride is converted into manganese sulphate and hydrochloric acid by the sulphuric acid. The following equation therefore expresses the final result, but does not take into account that there are several stages in the reaction—

Bromine and iodine are obtained in a precisely similar manner by treating the liquid containing the bromide or iodide with manganese dioxide and sulphuric acid.

Another process for the manufacture of chlorine has been recently introduced by Deacon, which consists in passing a mixture of hydrochloric acid gas and air through a heated brickwork chamber filled with pieces of firebrick or marble which have been soaked in a solution of copper sulphate and dried. The hydrogen of the hydrochloric acid forms water with the oxygen of the air, and chlorine is liberated, but the precise nature of the changes by which this is effected is not known. The reaction is at its maximum at a temperature of about 500°C ., which is much below that at which oxygen alone acts upon hydrochloric acid to form water and chlorine; the copper sulphate is but little affected, although a certain amount is always transformed into chloride. There can be no doubt, however, that the decomposition is the result of recurrent action, and another somewhat similar method of obtaining chlorine may be quoted in illustration. Thus, when a mixture of silica and sodium chloride is heated to redness in a current of oxygen, chlorine is evolved, and the chloride is converted into silicate—

but on passing hydrochloric acid gas over the silicate it is re-converted into the chloride and silica—

Hence, by passing hydrochloric acid together with air over the mixture of silica and chloride, a continuous evolution of chlorine is obtained, reaction in the one direction having no sooner taken place than reaction in the opposite direction sets in. There can be little doubt that the production of chlorine by Deacon's process is, in a similar manner, the result of a series of changes in opposite directions, the nature of which, however, remains to be discovered.

Chlorine is very readily condensed by a pressure of about 4 atmospheres at 15°C ., or by cold alone at about -50°C ., into a yellow mobile liquid of specific gravity about 1.33, but it has not been solidified. Bromine has at 0°C . the specific gravity 3.188; it boils at $59^\circ.5 \text{C}$., yielding a dense red vapour, and solidifies at $-24^\circ.5 \text{C}$. Iodine melts at 107°C ., and boils at about 175°C ., yielding a magnificent purple vapour. Chlorine gas and the vapour of bromine and iodine have a pungent, irritating, disagreeable odour, and are irrespirable. Water at 10°C . dissolves about 2.5 times its bulk of chlorine, and about 3 per cent. of bromine, but iodine is very sparingly soluble in water. When chlorine is passed into a mixture of crushed ice and water a crystalline hydrate, $\text{Cl}_2 + 10\text{H}_2\text{O}$, is produced, and a similar compound of bromine, $\text{Br}_2 + 10\text{H}_2\text{O}$, may be obtained, but iodine does not furnish a hydrate.

The halogens furnish with hydrogen compounds in which a single atom of hydrogen is united with a single atom of the halogen, viz. :—

The conditions under which hydrogen and chlorine enter into reaction have already been described, and we have seen that no change of volume occurs in the formation of hydrogen chloride from its elements. A mixture of hydrogen and bromine vapour does not explode on the application of flame, but hydrobromic acid is slowly formed when the mixture is heated; hydriodic acid is also produced when iodine is heated in hydrogen. Gore has shown that hydrofluoric acid may be prepared by heating silver fluoride in an atmosphere of hydrogen—

and he finds that one volume of hydrogen in uniting with fluorine produces two volumes of hydrofluoric acid gas, thus proving that the constitution of hydrogen fluoride is similar to that of hydrogen chloride, bromide, and iodide. Hydrogen chloride or hydrochloric acid is usually prepared by gently heating a mixture of sodium chloride or common salt and concentrated sulphuric acid, diluted with a small quantity of water—

Hydrogen bromide and iodide cannot be prepared in this manner from metallic bromides and iodides, as they are partially decomposed by concentrated sulphuric acid, bromine or iodine being liberated; this decomposition takes place much more readily with hydriodic acid than with hydrobromic acid—

Hydrobromic and hydriodic acid are therefore usually prepared by the action of water on the compounds of phosphorus with bromine and iodine; thus—

Hydrogen fluoride is procured by gently heating finely powdered calcium fluoride or fluor-spar with concentrated sulphuric acid in leaden or platinum vessels, or by strongly heating potassium hydrogen fluoride in a platinum retort—

The compounds of hydrogen with the halogens, or, as they are frequently termed, the haloid acids, are not only similar in composition, but they resemble each other very closely in properties. Thus, hydrogen chloride, bromide, and iodide at ordinary atmospheric temperatures are colourless transparent gases, which fume strongly in moist air, whilst hydrogen fluoride is a highly volatile colourless liquid, of specific gravity .988 at $15^\circ.7 \text{C}$., which boils at $19^\circ.4 \text{C}$.; its vapour fumes strongly in moist air. At a temperature of 10°C ., under a pressure of 40 atmospheres, hydrogen chloride is condensed to a colourless liquid of specific gravity 1.27, but it has never been solidified; hydrogen bromide and iodide are still more readily liquefied, and both may be caused to solidify, the former at -73°C ., and the latter at -51°C .

The circumstances which attend the formation of hydrogen chloride, bromide, and iodide from their elements, and

their general behaviour, show that the affinity of chlorine for hydrogen is much greater than that of bromine, whilst that of bromine is greater than that of iodine; and as already pointed out (p. 475), a considerable amount of heat is developed in the formation of hydrogen chloride, but a less amount in the formation of hydrogen bromide, and the production of hydrogen iodide from its elements involves the absorption of heat. We have seen, however, that the heat developed or absorbed in the formation of these compounds cannot be regarded as an absolute measure of the affinity of chlorine, bromine, and iodine for hydrogen, since there is an expenditure of energy due to the change of state, the three compounds being gases, but one being formed from two gases, the second from a gas and a liquid, and the third from a gas and a solid. Moreover, as we believe that the molecules which enter into reaction consist each of two atoms, the combination of the dissimilar atoms to form molecules of hydrogen chloride, bromide, and iodide must be preceded by the separation of the similar atoms which constitute the molecules of hydrogen, and of chlorine, bromine, and iodine, and there must be an expenditure of energy to effect this separation; it appears probable that different amounts of energy are expended in separating the atoms of chlorine, of bromine, and of iodine from each other, and we may further assume as probable that the amount of energy expended in the separation of the atoms is greater in the case of chlorine than of bromine, and greater in the case of bromine than of iodine, although at present there is scarcely any experimental evidence which enables us to draw conclusions of any value in proof of this.

Hydrogen fluoride is miscible with water in all proportions, and much heat is developed on mixing the two substances; hydrogen chloride, bromide, and iodide are also extremely soluble in water, forming colourless strongly acid solutions. Water at 0° C. absorbs ·825 of its own weight, or about 492 times its bulk, of hydrogen chloride gas, increasing in volume about one-third, and acquiring a density of about 1·23. This saturated solution consists of hydrogen chloride and water in about the proportions indicated by the formula $\text{HCl} + 3\text{H}_2\text{O}$; it fumes strongly, and when heated it gives off hydrogen chloride until at 112° C. a more dilute solution distils over, corresponding approximately in composition with the formula $\text{HCl} + 8\text{H}_2\text{O}$. A weaker solution when heated parts with water until it acquires this composition, and then distils unchanged. In like manner, a solution containing about 48 per cent. of hydrogen bromide distils unchanged at 125° C., and a solution containing about 57 per cent. of hydrogen iodide boils constantly at 127° C.; these solutions correspond approximately in composition with the formulæ $\text{HBr} + 5\text{H}_2\text{O}$ and $2\text{HI} + 11\text{H}_2\text{O}$. A solution of hydrogen fluoride approximately of the composition $\text{HF} + 2\text{H}_2\text{O}$ distils unchanged at 120° C. Roscoe's experiments have shown, however, that the composition of these solutions varies with the pressure, and that there exists for each pressure a solution of corresponding strength which undergoes no change in composition when distilled under this pressure, and therefore has a constant boiling point. Hence, the apparent constancy of composition cannot be regarded as proof of the existence of a definite hydrate corresponding in composition to that of the solutions obtained on distilling under a given pressure. There is no evidence, however, to invalidate, but much to support the conclusion that the haloid acids do not dissolve in water as such, but that they form definite hydrates; and if it be admitted that their solutions contain definite hydrates, their behaviour is precisely similar to that of other compounds which decompose when heated, but furnish products which can reunite to form the parent compound.

According to Thomsen's determinations, the amounts of

heat developed when gaseous hydrochloric, hydrobromic, and hydriodic acids are dissolved in water, in the proportion of 1 molecule of the acid to 400 molecules of water, are as follows—

In the dissolution of hydrogen chloride, 17,314 heat-units.
 " " " bromide, 19,207 " "
 " " " iodide, 19,207 " "

The development of so large an amount of heat, although, doubtless, in a great measure arising from the change from the gaseous to the liquid state, may be regarded as evidence that the acids really enter into combination with water, and are not merely dissolved; it may be noticed also that the same amounts of heat are developed in dissolving hydrogen bromide and iodide, and that their solutions, which under the ordinary atmospheric pressure distil unchanged, have nearly the same boiling point, and correspond approximately in composition.

Solutions of hydrogen chloride and bromide may be preserved unchanged, but the solution of hydrogen iodide gradually becomes brown, especially on exposure to light, owing to the separation of iodine, the hydrogen being oxidized by the oxygen of the air—

On the other hand, solutions of chlorine or bromine in water may be preserved unchanged in the dark, but when they are exposed to light oxygen is evolved, and hydrogen chloride or bromide produced—

A solution of iodine does not undergo alteration. In the presence of substances which have a tendency to enter into reaction with oxygen, water is often readily decomposed in this manner by chlorine and bromine without the aid of light, but iodine seldom effects this change; thus, on passing chlorine into a solution of sulphurous acid, the latter is oxidized to sulphuric acid—

The bleaching action which is powerfully exerted by chlorine in presence of water, and less powerfully by bromine, is in most cases the result of a similar change, the substance bleached being usually one which has a tendency to enter into reaction with oxygen.

Chlorine readily displaces bromine and iodine from their compounds with hydrogen and other elements, and, similarly, bromine displaces iodine; indeed the affinity of chlorine for other elements, with few exceptions, is superior to that of bromine, the affinity of bromine being in like manner superior to that of iodine. The decomposition of many chlorine compounds by the corresponding bromine and iodine compounds, and of bromine compounds by the corresponding iodine compounds, would appear at first sight to be in contradiction to this statement, but on examination of all such reactions it is found that they involve a development of heat, and therefore are perfectly normal in character. For example, silver chloride is converted into silver iodide by digestion with an aqueous solution of hydriodic acid—

It will be obvious that, in a molecule of silver iodide and a molecule of hydrogen chloride, the same quantity of the same elements is present as in a molecule of silver chloride and of a molecule of hydrogen iodide. But in the formation of the latter system from its elements, less heat is developed than in the formation of the former; hence reaction in the direction indicated by the above equation is attended with the development of heat. Thus, in the formation of a mole-

cule of dissolved hydriodic acid from its elements 13,170 units of heat are evolved, and about 34,800 units of heat are developed in the production of a molecule of silver chloride; whereas 39,320 units of heat are developed in the formation of a molecule of dissolved hydrochloric acid from its elements, and about 18,650 units in the production of a molecule of silver iodide. But—

$$(34,800 + 13,170) - (18,650 + 39,320) = -10,000$$

that is to say, the action of hydriodic acid on silver chlorido is attended with the development of no less than 10,000 units of heat.

All metals which decompose water at a red heat or at lower temperatures decompose a solution of hydrogen chloride with evolution of hydrogen, and form the corresponding metallic chloride, but with very different degrees of readiness; thus—

According to Thomsen, the amounts of heat developed in the production of 2 grammes of hydrogen by the action of various metals on a dilute solution of hydrogen chloride are as follows:—

Lithium.....	125,860	heat-units.
Potassium.....	123,700	" "
Sodium.....	114,380	" "
Magnesium.....	108,290	" "
Aluminium.....	79,880	" "
Manganese.....	49,360	" "
Zinc.....	31,200	" "
Iron.....	21,310	" "
Cadmium.....	17,610	" "
Lead.....	4,130	" "

Exact comparative observations of the degrees of readiness with which the various metals evolve hydrogen from a solution of hydrogen chloride have not as yet been made, but from ordinary observations it appears that those act most readily which develop the greatest amount of heat when dissolved. It is very difficult to compare the behaviour of different metals, however, since minute quantities of impurity exert a most remarkable influence; thus, ordinary zinc and iron dissolve with the greatest readiness in a dilute solution of hydrogen chloride, but the pure metals are only slowly dissolved.

Hydrogen bromide and iodide closely resemble hydrogen chloride in their behaviour with metals; mercury, however, which is not affected by hydrogen chloride or bromide, slowly dissolves in hydrogen iodide. Hydrogen fluoride not only acts with great readiness upon all metals which are dissolved by the other haloid acids, but likewise on many which these acids do not attack,—copper and silver, for example; and it also dissolves many elements which are insoluble in all other acids, such as silicon, boron, titanium, tantalum, and zirconium, with evolution of hydrogen. Gore has shown that anhydrous liquid hydrogen fluoride and chloride are, in most cases, much less energetic in their chemical reactions than their aqueous solutions; this is probably because the products which are formed in the first instance, being insoluble or difficultly soluble in the acid, form a coating on the surface of the substance submitted to the action of the acid, and thus preserve it from further action, or cause the action to take place more slowly; when water is present the product is dissolved, and thus a fresh surface is continually exposed.

The haloid acids readily enter into reaction with most metallic oxides, forming water and the corresponding compound of the metal with the halogen; thus—

Hydrogen fluoride is capable of dissolving some oxides, such as silica, SiO_2 , for example, which are not affected by the other haloid acids. It is in consequence easily distinguished from the other haloid acids by the powerful corrosive action which it exerts on glass.

The haloid acids also readily enter into reaction with, or neutralize, the hydroxides, forming water and the corresponding fluoride, chloride, bromide, or iodide—

The thermochemical behaviour of hydrochloric acid with hydroxides has already been discussed.

Chlorine enters into reaction with many of the elements at ordinary atmospheric temperatures, and with all of them, with few exceptions, at more or less elevated temperatures; its union with phosphorus, and with finely divided arsenic, antimony, tin, and copper, is attended with combustion. Bromine and iodine closely resemble chlorine in their behaviour with other elements; the union of bromine with other elements, however, appears always to take place less readily, and to be accompanied by the development of less heat than is the case with chlorine, and the affinity of iodine for most other elements is still weaker than that of bromine. The iodides also are usually less stable than the corresponding bromides, which are usually less stable than the corresponding chlorides. The compounds of the halogens with metals and with positive elements generally are mostly stable in presence of water, but their compounds with negative elements are mostly decomposed by water, and the halogen separated in the form of haloid acid.

The same element does not always enter into combination with chlorine, bromine, and iodine in the same proportions; thus, phosphorus forms a stable trichloride, PCl_3 , and an unstable pentachloride, PCl_5 ; a stable tribromide, PBr_3 , and a pentabromide, PBr_5 , less stable than the pentachloride; but with iodine it forms the compounds PI_3 and PI_5 . Many elements furnish compounds with fluorine containing a higher proportion of fluorine than corresponds to the amount of chlorine in their highest chlorides, or they form stable fluorides but unstable chlorides, bromides, and iodides; for example, phosphorus pentafluoride, PF_5 , is not decomposed by heat, whereas the pentachloride, PCl_5 , is readily resolved into the trichloride and chlorine by heating.

The halogens do not only combine with hydrogen and other elements, however, but they are capable of forming compounds with each other. Thus, by the action of iodine on silver fluoride, Gore has obtained iodine pentafluoride, IF_5 , as a colourless highly volatile liquid; iodine at once enters into reaction with chlorine, and is first converted into liquid iodine chloride, ICl , but ultimately yields iodine trichloride, ICl_3 , which is a crystalline solid; with bromine iodine appears to furnish only a liquid monobromide, IBr . In like manner, bromine forms with chlorine a liquid bromine chloride, BrCl .

On account of its great affinity for hydrogen, chlorine readily enters into reaction with a large number of hydrogenized carbon compounds, and displaces the hydrogen more or less completely. Thus, methane, CH_4 , when submitted to the action of chlorine, is successively converted into monochloromethane, CH_3Cl , dichloromethane, CH_2Cl_2 , trichloromethane, CHCl_3 , and tetrachloromethane, CCl_4 ,—the displaced hydrogen being evolved as hydrogen chloride. Bromine behaves similarly, but enters into such reactions much less readily; iodine seldom, if ever, behaves in this way.

Compounds of the Halogens with Oxygen.

Oxides of fluorine are unknown, and the oxides of the remaining halogens are very imperfectly investigated. Three oxides of chlorine have been prepared, viz. :—

At ordinary temperatures these compounds are greenish-yellow gases, remarkable on account of their instability, being decomposed with explosive violence by very slight elevations of temperature. Their instability is accounted for by the circumstance that their decomposition is attended with the development of a very considerable amount of heat; thus, according to Thomsen, the formation of gaseous hypochlorous anhydride from its elements would involve the absorption of 18,040 units of heat per molecule, and consequently this amount is developed when the anhydride is resolved into its elements. The explanation of the absorption of heat in the formation of the oxides of chlorine would appear to be that more energy must be expended in separating the atoms of oxygen from each other, and in separating the atoms of chlorine from each other, than is produced by the combination of the chlorine and oxygen atoms.

Oxides of bromine are also unknown, and since thermochemical investigation has shown that oxygen has less affinity to bromine than to chlorine, their non-formation in reactions corresponding to those by which the oxides of chlorine are produced is no longer surprising.

Iodine differs entirely from chlorine and bromine with regard to its affinity for oxygen. Only one oxide of iodine is known, viz., iodic anhydride, I_2O_5 , but this is a white crystalline substance of considerable stability, and, according to Thomsen's determination, the formation of this compound from its elements would involve the development of no less than 44,860 units of heat per molecule. It has not been directly produced from its elements, although its formation in this manner is not improbable.

Chlorous anhydride is prepared by passing dry chlorine gas over dry mercuric oxide—

It may be condensed by surrounding the receiver with a mixture of ice and salt, and thus obtained as a deep red liquid which emits a vapour of a deeper colour than that of chlorine, having a peculiar suffocating chlorous smell. It is with the greatest readiness decomposed into chlorine and oxygen, the warmth of the hand being sufficient to cause it to explode. Water dissolves about 200 times its bulk of the gas, forming a pale yellow solution of hypochlorous acid, which has an acid but not sour taste—

By neutralizing this solution with metallic hydroxides or carbonates corresponding metallic hypochlorites are formed, but these salts are usually prepared by passing chlorine into water in which the metallic hydroxide or carbonate is suspended or dissolved, the liquid being carefully cooled—

A concentrated solution of hypochlorous acid decomposes rapidly, even when kept in ice; a dilute solution is more stable, but is decomposed by boiling into chloric acid, water, chlorine, and oxygen. These substances are probably the products of several distinct changes, such as are represented by the following equations—

Hypochlorous acid, however, readily decomposes hydro-

chloric acid, and the chlorine produced is probably the result of reaction between these bodies—

Hypochlorous acid is a very powerful oxidizing agent, and rapidly converts many of the elements into their highest oxides, at the same time liberating chlorine; indeed, in many respects it is not unlike ozone and hydrogen dioxide in its chemical behaviour, and it enters into reaction with the latter in the manner represented by the equation—

Like chlorine, it possesses powerful bleaching properties. The hypochlorites also act as bleaching agents, probably by yielding oxygen to the substance submitted to their action, but less powerfully than the free acid.

The bleaching powder or chloride of lime of commerce is prepared by exposing slaked lime or calcium hydroxide to the action of chlorine gas. There has been much discussion among chemists as to the constitution of the compound so produced, and it is only quite recently that evidence has been obtained which enables us to pronounce a decision. The composition of bleaching powder is represented by the formula CaCl_2O , whereas calcium hypochlorite would be represented by the formula CaCl_2O_2 ; it was therefore supposed that the bleaching powder was a mixture of calcium chloride and calcium hypochlorite, since $\text{CaCl}_2 + \text{CaCl}_2\text{O}_2 = 2\text{CaCl}_2\text{O}$. Apparently, however, it is a distinct compound intermediate between calcium chloride and calcium hypochlorite, thus—

and its formation from calcium hydroxide may be represented by the following equation—

On dissolving in water, according to Kingzett, it is resolved into calcium chloride and calcium hypochlorite, which may be obtained in crystals by carefully concentrating the solution in vacuo, so that a solution of bleaching powder is correctly regarded as a solution of calcium hypochlorite—

Solutions of hypochlorites are very unstable, and when boiled they furnish a mixture of chloride and chlorate; thus—

It is on this account that it is necessary in preparing hypochlorites to act on a cold solution of the hydroxide, since if the solution be heated chlorate is formed by the decomposition of the hypochlorite.

The chlorates are very stable compounds as compared with the hypochlorites. They may be obtained well crystallized, and are all soluble in water. They are destitute of bleaching properties. The most important chlorate is potassium chlorate, KClO_3 , which is chiefly interesting as a source of oxygen, and is largely employed in the manufacture of fireworks; the resolution of this salt into oxygen and potassium chloride is attended with a development of heat amounting to 9700 units per molecule decomposed.

By exactly decomposing a solution of barium chlorate with sulphuric acid, a solution of chloric acid, HClO_3 , is obtained, which may be separated from the insoluble

barium sulphate by filtration, and concentrated by evaporation in vacuo until it forms a syrupy liquid:—

Chloric acid has a faint chlorous odour, and a powerfully acid reaction; it is instantly decomposed by contact with organic matter, with charring, and frequently even with ignition. In diffused daylight it gradually undergoes spontaneous decomposition, and when heated to a little above 100°C . it is rapidly converted into perchloric acid, water, chlorine, and oxygen—

It is a powerful oxidizing and bleaching agent

Chloric acid serves for the preparation of the remaining oxides and oxy-acids of chlorine. To prepare chlorous anhydride from it, 10 parts of pure benzene are dissolved in 100 parts of concentrated sulphuric acid, and when the mixture has cooled 12 parts of pulverized potassium chlorate are added. The chloric acid liberated from the chlorate under these circumstances is deprived of a portion of its oxygen by the benzene, which is oxidized, and at the same time, by the dehydrating influence exercised by the sulphuric acid, the elements of a molecule of water are removed and chlorous anhydride is liberated; thus—

The mixture is heated to about 50°C . in a flask having a delivery tube fitted to its neck by grinding, and blown out in several places into small bulbs; the gas, after passing through water contained in these bulbs, is conducted into a glass tube surrounded by a mixture of ice and salt. The condensed liquid deposits crystals of a hydrate of chlorous acid, and the supernatant liquid decanted immediately into a small cooled glass cylinder forms the nearly anhydrous oxide Cl_2O_2 . Liquid chlorous oxide or anhydride thus obtained is very mobile, is of a deep red colour, and has a specific gravity of 1.330 to 1.387 at 0°C .; it boils a little above 0°C ., and it explodes somewhat readily at a few degrees above 0°C . The specific gravity of the gaseous oxide accords with that required by the formula Cl_2O_2 . Chlorous anhydride is not very soluble in water, 100 grammes of water at 23°C . dissolving 5.65 grammes of the oxide (Brandan). The solution of chlorous acid, HClO_2 , thus obtained, has powerful bleaching and oxidizing properties; when it is heated, chloric and hydrochloric acids are formed and chlorine evolved. By neutralizing the solution with hydroxides of the alkali or alkaline earth metals corresponding chlorites are obtained, which are soluble; and from these the insoluble chlorites of lead and silver are obtained by double decomposition. Chlorites are decomposed by the feeblest acids, even by carbonic acid.

When fused potassium chlorate is carefully treated with concentrated sulphuric acid, chlorine dioxide or peroxide is evolved; the reaction by which it is produced, it is stated, is represented by the following equation—

The so-called *euchlorine* gas, which is obtained when a mixture of a chlorate and hydrochloric acid is gently heated, appears to be a mixture of chlorine peroxide with chlorine. Chlorine peroxide is gaseous at ordinary temperatures, but by means of a mixture of ice and salt it may be condensed to a red liquid. It has a deep greenish-yellow colour, and peculiar sweet chlorous odour; a slight degree of heat and mere contact with organic matters at once determine its explosion. Like all the oxides of chlorine, it acts rapidly upon mercury and most metals. From Pebal's recent experiments there appears to be no

doubt that chlorine peroxide is correctly represented by the formula ClO_2 , and it is, therefore, to be included with nitric oxide and the few other compounds in which we must suppose an odd number of affinities are free (see p. 473). It is absorbed by alkaline solutions, forming a mixture of a chlorite and a chlorate—

In this respect especially it differs from the other oxides of chlorine.

The only remaining chlorine compound to be considered is perchloric acid, HClO_4 . It may be formed from chloric acid by oxidation, but, according to Roscoe, the best method of preparing it consists in boiling down a solution of chloric acid; lower oxides of chlorine escape, and a solution of perchloric acid is left. It may also be obtained from potassium perchlorate, formed by heating potassium chlorate, by distilling it with sulphuric acid.

Aqueous perchloric acid may be concentrated by boiling till it attains a temperature of 203°C ., after which it passes over in the form of an oily liquid which approximately has the composition $\text{HClO}_4 + 2\text{H}_2\text{O}$. By distilling this hydrate with twice its volume of sulphuric acid, nearly pure perchloric acid is obtained.

The pure acid is a colourless very soluble liquid, of specific gravity 1.782 at $15^\circ 5' \text{C}$. In this state it is one of the most powerful oxidizing agents known; a single drop brought in contact with charcoal, wood, or almost any organic substance, immediately causes an explosive combustion, which in violence almost equals the sudden decomposition of the so-called chloride of nitrogen. It produces frightful burns if allowed to fall upon the skin. It undergoes spontaneous decomposition at ordinary temperatures, and cannot be distilled unchanged. It unites very energetically with water, and when mixed with it in suitable proportions forms the hydrate $\text{HClO}_4 + \text{H}_2\text{O}$; this is a white crystalline substance, which melts at 50°C ., and undergoes decomposition when heated to 110°C ., splitting up into the pure acid and the oily hydrate above mentioned.

Aqueous perchloric acid has a sour taste, and reddens litmus strongly, but does not bleach; it dissolves iron and zinc with evolution of hydrogen, and when dilute it is unaffected by hydrogen sulphide and sulphurous acid, which reduce all other oxy-acids of chlorine. Perchloric acid, in fact, is distinguished from all other oxidized chlorine compounds by its superior stability, oxygen being withdrawn from it with comparative difficulty.

The results of Thomsen's thermochemical examination of various reactions which are involved in the formation of some of the oxidized chlorine compounds are exhibited in the following table. The symbols in the first column indicate the nature of the reaction, and the numbers in the second column the units of heat developed or absorbed,—the reaction being supposed to take place between the substances of which the symbols are separated by commas. Thus, the line

is to be read as meaning that, in the formation of a molecule (in grammes) of gaseous chlorine oxide from chlorine and oxygen, 18,040 units of heat would be absorbed. Similarly, the reaction $\text{Cl}_2\text{O}, \text{Aq}$, that is to say, the absorption of gaseous chlorine oxide by water is attended with the development of 9440 units of heat; hence the reaction $\text{Cl}_2, \text{O}, \text{Aq}$, or the formation of a solution of hypochlorous acid (two molecules) from chlorine, oxygen, and water would involve the absorption of 8600 units of heat. For these, as in all Thomsen's experiments, the determinations were made at about 18°C .

Reaction.	Units of heat developed or absorbed.	Remarks.
Hypochlorous acid.	Cl_2, O	-18,040 Gaseous oxide.
	$\text{Cl}_2\text{O}, \text{Aq}$	+ 9,440 Absorption of gas by water.
	$\text{Cl}_2, \text{O}, \text{Aq}$	- 8,600 Formation of aqueous acid.
	$\text{Cl}, \text{O}, \text{H}, \text{Aq}$	+29,880 Ditto from $\text{Cl}, \text{O}, \text{H}$, and water.
	$\text{ClOHAq}, \text{KOH Aq}$	+ 9,980 Heat of neutralization.
Chloric acid.	$\text{Cl}_2, \text{O}_5, \text{Aq}$	-20,480 Formation of aqueous acid from chlorine, oxygen, and water.
	$\text{Cl}, \text{O}_3, \text{H}, \text{Aq}$	+23,940 Ditto from chlorine, oxygen, hydrogen, and water.
	$\text{ClO}_3\text{HAq}, \text{KOH Aq}$	+13,760 Heat of neutralization.
	$\text{ClO}_3\text{K}, \text{Aq}$	-10,040 Heat of dissolution.
	KCl, O_3	9,770 Oxidation of dry KCl .
	$\text{K}, \text{Cl}, \text{O}_3$	+95,840 Formation of crystalline KClO_3 from its elements.
	$\text{HCl Aq}, \text{O}_3$	-15,380 Oxidation of HCl in solution.
	$\text{KCl Aq}, \text{O}_3$	-15,370 Oxidation of KCl in solution.

In this table, and in all similar tables, the reactions are represented *empirically*, and the figures after the symbols merely indicate the number of atoms which enter into the composition of the compound. Thus, the reaction expressed as Cl_2, O , merely refers to the formation of a molecule (in grammes) of hypochlorous anhydride, Cl_2O , from chlorine and oxygen, and the arrangement of the symbols in this manner is not intended to indicate that the compound is formed from a *molecule* of chlorine and an *atom* of oxygen. The symbol *Aq* is intended to indicate that an *excess* of water is employed, *i.e.*, such an amount that no appreciable development of heat would be caused by the addition of a further quantity.

When bromine is added to an aqueous solution of sodium hydroxide, sodium hypobromite, NaOBr , is formed, but this is much less stable than the corresponding hypochlorite, and is readily converted into bromate and bromide. The bromates and bromic acid resemble the chlorates and chloric acid, but are much less stable; thus, a solution of bromic acid is decomposed at 100°C ., giving off bromine and oxygen, and all reducing agents decompose it with facility. The inferior stability of the oxidized compounds of bromine as compared with those of chlorine appears to indicate that the affinity of bromine to oxygen is less than that of chlorine; this is entirely confirmed by thermochemical investigation, Thomsen having obtained the following values for bromic acid:—

$\text{Br}_2, \text{O}_3, \text{Aq}$	= -43,520	Formation of the aqueous acid from bromine, oxygen, and water.
$\text{Br}, \text{O}_3, \text{H}, \text{Aq}$	= +12,420	Formation of the aqueous acid from its elements.
BrHAq, O_3	= -15,960	Oxidation of hydrobromic acid.
$\text{KOH Aq}, \text{BrO}_3\text{HAq}$	= +13,750	Heat of neutralization.

When iodine is added to solutions of alkaline hydroxides or carbonates, alkaline hypoiodites corresponding to the hypochlorites are perhaps formed, but as yet have not been isolated. By dissolving iodine in a warm solution of potassium hydroxide a mixture of potassium iodide and iodate is produced—

Iodine is converted into iodic acid by heating with the strongest nitric acid, and by the action of many other oxidizing agents; but iodic acid is usually prepared from barium iodate, which is decomposed with the necessary

quantity of sulphuric acid. Potassium iodate is most readily prepared by passing chlorine into water in which iodine is suspended until the latter is dissolved, then adding a corresponding quantity of potassium chlorate and warming; the iodine is converted into monochloride, which enters into reaction with the chlorate, and chlorine is evolved—

By adding a solution of barium hydroxide, insoluble barium iodate is precipitated, from which, as pointed out, iodic acid may be prepared.

Iodic acid separates from its solution on spontaneous evaporation in crystals of the composition HIO_3 ; when heated to 120°C . these crystals lose water, and apparently form the compound HI_3O_8 or $\text{HIO}_3 + \text{I}_2\text{O}_5$; at about 170°C . this compound is resolved into water and iodic anhydride, I_2O_5 . Iodic anhydride is a crystalline substance, which readily dissolves in water, forming iodic acid; when heated to about 370°C . it is resolved into oxygen and iodine. Iodic acid is a powerful oxidizing agent, being easily decomposed by deoxidizing agents; hydriodic acid reduces it to iodine and water—

The chlorates and bromates are mostly easily soluble, and the corresponding salts are isomorphous; but the iodates are mostly difficultly soluble, and with the exception of barium iodate, are not isomorphous with the corresponding chlorates and bromates. Moreover, chloric and bromic acids furnish but one class of salts, of which potassium chlorate, KClO_3 , is typical; but iodic acid, in addition to the normal iodates, such as potassium iodate, KIO_3 , forms acid salts. These differences appear to indicate that iodic acid differs in constitution from the other acids, and Thomsen has pointed out that it is probably a dibasic acid of the formula $\text{H}_2\text{I}_2\text{O}_6$, since it is readily converted into water and the anhydride I_2O_5 , a property which is characteristic of dibasic but not of monobasic acids; and since it furnishes acid salts, which is also characteristic of polybasic but not of monobasic acids, and is isomorphous with succinic acid, which is dibasic. Normal potassium iodate would therefore have the formula $\text{K}_2\text{I}_2\text{O}_6$, and the so-called diiodate is probably the acid salt KHI_2O_6 .

This view of the constitution of iodic acid is rendered the more probable by the behaviour of periodic acid, the disodium salt of which separates as a crystalline powder on passing chlorine into a solution of sodium iodate and sodium hydroxide; the reaction is empirically represented by the equation—

To prepare the acid from this salt, it is dissolved in nitric acid, and silver nitrate added; the precipitate of disilver periodate is dissolved in hot dilute nitric acid, and the solution concentrated at a moderate heat until a salt of the composition AgIO_4 crystallizes out. By treating this salt with cold water it is decomposed, disilver periodate and periodic acid being produced:—

to obtain the latter the solution is evaporated.

Periodic acid separates from its aqueous solution in colourless crystals of the composition H_5IO_6 , which are not altered at 100°C ., but melt at 130°C ., and when heated to a higher temperature give off water and oxygen, leaving iodic anhydride.

Periodic acid furnishes a complex but extremely interesting series of salts. Thus, it forms two potassium salts, one of which has the composition KIO_4 , and is obtained on passing chlorine into a solution of potassium iodate and potassium hydroxide; the second is represented

by the formula $K_4I_2O_7$, and is obtained on dissolving the former in potassium hydroxide solution. The latter crystallizes with 9 molecules of water, which, however, it loses when exposed over sulphuric acid. Corresponding sodium salts exist. That which has the composition $NaIO_4$ crystallizes either in the anhydrous state, or with 3 molecules of water, which it readily loses in dry air; the second salt, the formation of which was above described, separates in crystals of the composition $Na_4I_2O_9 + 2H_2O$, and is only rendered anhydrous by heating to $220^\circ C$. Three silver salts are known, represented by the formulae $AgIO_4$, $Ag_4I_2O_9 + 3H_2O$, and Ag_5IO_5 ; the second of these loses 2 molecules of water at $100^\circ C$, but the third only at $200^\circ C$. The barium salt $Ba_2I_2O_9$ separates in the anhydrous state from strongly acid solutions, but when prepared by precipitating a solution of the acid with barium hydroxide, or of an alkali salt with a barium salt, it contains 6 or 7 molecules of water, which are only completely removed by heating to $300^\circ C$. It also furnishes a lead salt of the composition $Pb_3I_2O_{10} + 2H_2O$, and amongst other magnesium salts one of the composition $Mg_3I_2O_{11}$, which crystallizes with 6 and with 9 molecules of water.

The question now arises—What is the nature of the relation between these various salts? By the chemical method alone it is extremely difficult, if not impossible, to decide, but from Thomsen's thermochemical investigation of the acid there can be little doubt as to the answer we should make to this question. When successive molecules of potassium hydroxide are added to a solution of 1 molecule of the acid H_5IO_6 the amounts of heat evolved are as follows:—

On the addition of the 1st molecule,	5,150 heat-units.
2d "	21,440 "
3d "	3,150 "
4th and 5th "	2,300 "

The first and second molecules, therefore, together cause the development of 26,590 units of heat, or of 13,295 units per molecule. But we have seen (p. 486) that on neutralizing a large number of acids, between 13,750 and 13,150 units of heat are developed per molecule of hydroxide added; and as the addition of further quantities of the hydroxide causes a comparatively slight development of heat there is little doubt from these results that the molecule H_5IO_6 is dibasic. But on account of the existence of salts, such as $K_4I_2O_9$, it appears desirable to double this formula, and to represent the molecule of periodic acid by the formula $H_4 \cdot I_2O_{12}H_6$. Several of the salts above alluded to may be regarded as derived from this molecule by the partial or total displacement of the hydrogen by metals; and we may term those which are formed by displacing 4 of the 10 atoms of hydrogen *normal* salts, while those in which 2, 4, or 6 of the remaining atoms of hydrogen are displaced may be called *basic* salts. Thus we have—

$Pb_2'' \cdot I_2O_{12}H_4Pb''; Mg_2'' \cdot I_2O_{12}H_2Mg_2''; Ag_4' \cdot I_2O_{12}Ag_6'$. That the tendency to form basic salts is slight in the case of the highly positive elements is also shown by the small amount of heat developed on the addition of the third, fourth, and fifth molecules of potassium hydroxide.

The anhydrous salts such as $K_4I_2O_9$ are to be regarded as derived from a distinct acid formed from the molecule $H_4 \cdot I_2O_{12}H_6$ by the withdrawal of the elements of 3 molecules of water. The salts, such as KIO_4 , which on account of its isomorphism with potassium permanganate, $K_2Mn_2O_8$, is more probably represented by the formula $K_2I_2O_8$, are, it may be supposed, also derived from a distinct acid, formed in a similar manner by the with-

drawal of the elements of a fourth molecule of water; these salts have the same empirical composition as the perchlorates, and as potassium perchlorate is isomorphous with the compound $K_2I_2O_8$, it is probable that it corresponds with it in composition, and that perchloric acid therefore is represented by the formula $H_2Cl_2O_8$. If this conclusion be correct, and chloric acid be correctly represented by the formula $HClO_3$, we have an explanation of the great difference which is observed in the properties of these two acids. Perchloric acid, we have seen, has a great tendency to combine with water, and its hydrates may be regarded as distinct acids, the liquid hydrate bearing the same relation to the acid $H_2Cl_2O_8$ that crystallized periodic acid bears to the hypothetical acid $H_2I_2O_8$, from which salts such as $K_2I_2O_8$ are derived. Basic perchlorates corresponding to the basic periodates are not known, but a cuprammonium salt and a lead salt have been obtained which apparently are derived from the crystalline hydrate of perchloric acid, the latter having the composition $Pb''Cl_2O_8 + PbH_2O_2$ or $Pb''Cl_2O_{10}H_2Pb''$.

It will have been noticed that the amount of heat developed on the addition of the first molecule of potassium hydroxide to the solution of periodic acid regarded as H_5IO_6 is much less than is usually observed with other acids, and the amount developed on the addition of the second molecule much greater; the two molecules together, however, produce an effect comparable with that observed in the case of other acids. But the salt produced on passing chlorine into a solution of potassium hydroxide has the composition $K_2I_2O_8$, so that the first action of potassium hydroxide on a solution of the acid $H_4 \cdot I_2O_{12}H_6$ apparently does not merely consist in the direct displacement of hydrogen in this acid by potassium; the elements of four molecules of water are also withdrawn, and since this latter operation involves the absorption of heat, the amount of heat finally developed in the reaction is but small. On the addition of a further quantity of hydroxide, however, change in the reverse order is effected, and hence the normal amount of heat is developed by the combined action of the two molecules of hydroxide. It is interesting also to observe that more heat is developed on adding the third than by the fourth and fifth molecules of hydroxide together, and to contrast this with the circumstance that the silver salt $Ag_4I_2O_{12}H_6$ loses the elements of two molecules of water at $100^\circ C$, but the elements of a third only at $200^\circ C$. Apparently there is a tendency on the part of potassium hydroxide to enter into reaction with the acid after the production of the normal salt $K_4I_2O_{12}H_6$; but salts containing a relatively larger proportion of potassium evidently cannot exist except in solution, and even then only to a limited extent.

We are now in a position also to explain the formation of sodium periodate by the action of chlorine on a solution of sodium iodate and sodium hydroxide. We have learnt that the action of chlorine on the latter is to produce sodium hypochlorite, and that this is a powerful oxidizing agent—

and there can be little doubt, therefore, that the iodate is at first oxidized by it, and converted into the salt Na_2IO_3 ; thus—

In presence of sodium hydrate and water, however, this salt is at once converted into the normal periodate—

The following are the results of Thomsen's thermochemical examination of iodine and periodic acids:—

lower specific gravity, viz., 1.98, but of higher melting point (120°C.); in the course of a few days, although the crystals maintain their prismatic form, they become opaque, and, on examination, are found to be converted into aggregations of minute octahedrons. This change of prismatic into octahedral sulphur is attended with the development of a considerable amount of heat, which is especially noticeable when the conversion is caused to take place rapidly by scratching the crystals. The transformation of the octahedral variety into the prismatic takes place at about the melting point of the former, a transparent crystal of octahedral sulphur being converted into an opaque mass of prismatic crystals when heated for some time to a temperature of $105^{\circ}\text{--}115^{\circ}\text{C.}$; also, when a saturated solution of sulphur in hot turpentine is allowed to cool, crystals of prismatic sulphur are at first deposited, but after a time, when the liquid has become comparatively cool, the crystals which separate are octahedral.

Prismatic sulphur is soluble in carbon disulphide and other menstrua which dissolve the octahedral modification; another modification, which is also soluble, but destitute of crystalline form, is obtained on addition of acids to solutions of alkaline polysulphides—

It has a greenish-white colour, and constitutes ordinary milk of sulphur; by keeping, it becomes gradually converted into octahedral sulphur. Sublimed sulphur, or flowers of sulphur, is probably closely allied to this form, but always contains a small proportion of insoluble sulphur.

When sulphur is heated to $260^{\circ}\text{--}300^{\circ}\text{C.}$ and then poured in a thin stream into cold water, it is converted into the so-called plastic modification, and is obtained as a soft yellowish-brown semitransparent mass, capable of being drawn out into fine elastic threads. In this state sulphur has the specific gravity 1.95, and is insoluble in carbon disulphide; in the course of a few hours, however, it again becomes brittle and almost entirely reconverted into the octahedral modification, the change being accompanied by the development of heat.

When the chloride of sulphur, S_2Cl_2 , is decomposed by water, it furnishes sulphur, hydrochloric acid, and thiosulphuric acid; the sulphur thus obtained is amorphous and insoluble in carbon disulphide, but is converted into octahedral sulphur by fusion, or by exposure for some time to a temperature of 100°C. Thiosulphuric acid also gradually decomposes into sulphur and sulphurous acid, and if a solution of a thiosulphate is decomposed by hydrochloric acid—

the sulphur which separates is soluble in carbon disulphide, but is obtained on evaporation of the solution in an amorphous condition, and cannot then be again dissolved in carbon disulphide; it is stated, however, that if the hyposulphite is decomposed by dilute sulphuric acid, the sulphur which separates is insoluble in carbon disulphide. When a solution of ordinary sulphur in carbon disulphide is exposed to sunlight, an amorphous insoluble modification separates; the reversion of this modification into octahedral sulphur is attended with the absorption of heat.

Several minor modifications of sulphur have been described, but it is not known whether the differences which they exhibit are inherent, or whether, as is not improbable, they are due to the presence of impurity.

There appears to be a relation between the modification formed in a reaction and the compound or compounds from

which it is obtained, since, generally, the sulphur separated from compounds in which it is associated with positive elements is soluble, whilst that separated from compounds in which it is associated with negative elements is insoluble in carbon disulphide; but the conditions under which the sulphur is separated doubtless exercise an important influence.

At present we have no knowledge as to the manner in which the various allotropes are related to each other; it has been suggested, however, that the differences between them are at least in some cases due to differences in molecular composition.

Several allotropic modifications of selenium are also known, but a tendency to form allotropes has not been observed in the case of tellurium.

Three principal modifications of selenium, corresponding to the three principal modifications of sulphur, may be distinguished, viz., (1), black crystalline selenium, of specific gravity about 4.80, which may be placed by the side of the octahedral variety of sulphur, being the form in which selenium separates when solutions of metallic selenides are exposed to the air, and since all other modifications are converted into it when heated to about 150°C. ; (2), red crystalline selenium, of specific gravity 4.46 to 4.51, which probably corresponds to monoclinic sulphur, as it has the same crystalline form, and may be obtained by rapidly cooling melted selenium; and (3), red amorphous selenium, of specific gravity about 4.3. This last corresponds to the amorphous allotrope of sulphur, and, as in the case of sulphur, it occurs in two modifications, the one soluble and the other insoluble in carbon disulphide. Black crystalline selenium, unlike octahedral sulphur, however, is insoluble in carbon disulphide, but the red crystalline allotrope is soluble, although to a much less extent than sulphur. The conversion of these modifications of selenium into each other is attended with development or absorption of heat, just as in the case of sulphur, and the melting points of the several modifications are different. Thus, if amorphous selenium, which melts a few degrees above 100°C. , be heated to about 96°C. , it quickly becomes crystalline, the change being attended with considerable rise of temperature, and the melting point rises to 217°C. The electrical conductivity of selenium is found to vary in a remarkable manner with the temperature, and is also influenced by light. Amorphous selenium is a non-conductor up to 80°C. , but from this temperature up to 210°C. its conductivity gradually increases, after which it again diminishes. Selenium which has been kept for several hours at 210°C. and then gradually cooled is especially sensitive to the influence of light, its conductivity increasing with the intensity of the light.

Sulphur, selenium, and tellurium form gaseous compounds with hydrogen, analogous in composition to water:—

Hydrogen sulphide may be produced directly from its elements by passing hydrogen gas into boiling sulphur, but it is always prepared by the action of a solution of hydrochloric or sulphuric acid on a metallic sulphide, that of iron being commonly employed—

The compounds of selenium and tellurium with hydrogen are obtained in a similar manner from metallic selenides and tellurides. Hydrogen and selenium also directly enter into reaction; the quantity of hydrogen selenide formed is apparently a function of the temperature; it increases from 250° to 260°C. , and decreases regularly from the latter point to 700°C.

Hydrogen sulphide, hydrosulphuric acid, or sulphuretted hydrogen gas, is transparent and colourless; it possesses a most offensive odour, and cannot be breathed with impunity, frequently giving rise to nausea and vertigo even when much diluted. It may be condensed by powerful pressure to an extremely mobile liquid, which solidifies when cooled in a bath of solid carbon dioxide and ether to a white transparent mass, which melts at -85°C . Hydrogen sulphide is readily inflammable, burning in air with a blue flame, and forming water and sulphur dioxide—

Most metals when heated in the gas decompose it, a metallic sulphide being produced, and hydrogen liberated. Hydrogen sulphide dissolves in water, a saturated solution containing about three times its volume of the gas; the solution has the odour and taste of the gas, and a slight acid reaction. It is gradually decomposed on exposure to the air, sulphur being deposited—

It is decomposed in a similar manner by nearly all oxidizing agents, and by the action of chlorine, bromine, and iodine—

Iodine, however, cannot decompose the gas at ordinary temperatures except in presence of water. This is because the reaction requires an absorption of heat. Thus, in the production of a molecule of hydrogen sulphide from hydrogen and sulphur in the state in which it separates when hydrogen sulphide is decomposed by iodine, 4500 units of heat are developed; but in the production of a molecule of hydriodic acid from its elements, 6000 units of heat are absorbed, so that the reaction indicated by the equation $\text{H}_2\text{S} + \text{I}_2 = 2\text{HI} + \text{S}$ would involve the absorption of $4500 + 2 \times 6000 = 16,500$ units of heat. That it takes place in presence of water is due to the fact that the dissolution of the hydriodic acid produced is attended with the development of $2 \times 19200 = 38,400$ units of heat; hence, when the reaction is effected in a dilute solution, heat is developed to the extent of $38,400 - 16,500 = 21,900$ units of heat. But it is found that the reaction takes place the less readily as the concentration of the solution increases, and that it ceases when the solution has attained a specific gravity of 1.56 at ordinary temperatures; in more concentrated solutions sulphur even dissolves with production of hydrogen sulphide and liberation of iodine. A simple explanation of this apparently anomalous result, however, is afforded by the observation that the heat developed by the absorption of equal quantities of hydriodic acid is less as the quantity of acid already dissolved in the water is greater. The amount of heat developed, therefore, diminishing as the quantity of hydriodic formed by the reaction in the liquid increases, at a certain point becomes equal to that absorbed in the decomposition of the hydrogen sulphide by the iodine, and the reaction ceases since it can no longer be attended with a development of heat.

This behaviour of iodine with hydrogen sulphide alone, or in presence of water, is one of the most striking illustrations of the fact that reactions involving the expenditure of energy cannot take place directly, and are only possible when the conditions are such that one or more of the products of the reactions enter into secondary reactions, so as to cause the development of more heat than is absorbed in the primary reaction.

The hydrogen in hydrogen sulphide may be displaced by metals,—the compounds formed by displacing one-half the hydrogen being termed sulphhydrates or hydrosulphides, whilst those in which the whole of the hydrogen is displaced are termed sulphides. These two classes of com-

pounds correspond to the metallic hydroxides and the metallic oxides respectively, and in many respects closely resemble them; the sulphur compounds, however, are, with few exceptions, far less stable than the corresponding oxygen compounds.

Hydrogen sulphide enters directly into reaction with the metallic hydroxides, exchanging its hydrogen for the metal; for example—

It therefore exhibits the behaviour of an acid. From Thomsen's experiments it appears that 7740 units of heat are developed on the addition of a solution of one molecule of sodium hydroxide to a solution of one molecule of hydrogen sulphide, and that the further addition of the hydroxide is without effect. Hydrogen sulphide is thus proved to be a *monobasic* acid, and this result also shows that when soluble sulphides, such as sodium sulphide, are dissolved in water, double decomposition occurs, thus: $\text{Na}_2\text{S} + \text{OH}_2 = \text{NaSH} + \text{NaOH}$, just as when sodium oxide, for example, is added to water: $\text{Na}_2\text{O} + \text{OH}_2 = 2\text{NaOH}$. It is uncertain, however, whether the decomposition of the sulphides by water in this manner is complete, or whether it is only partial, and the more complete the greater the quantity of water present.

The highly positive metals lithium, sodium, potassium, calcium, strontium, barium, and magnesium form soluble sulphides and hydrosulphides, but most of the sulphides of other metals are insoluble. The nature of many of the compounds precipitated from metallic solutions by hydrogen sulphide or an alkaline hydrosulphide is not well established; but in many cases apparently they are intermediate in composition between the hydroxides and hydrosulphides; the precipitate formed on the addition of an alkaline hydrosulphide to a solution of a zinc salt, for example, is probably a compound of this kind, and may be represented by the formula HO.Zn.SH ,—zinc hydroxide being HO.Zn.OH , and zinc hydrosulphide HS.Zn.SH . The solutions of salts of heavy metals, such as mercury and lead, furnish precipitates of the corresponding sulphides with hydrogen sulphide or alkaline hydrosulphides.

The hydrosulphides of certain elements, such as aluminium and chromium, cannot exist in presence of water, but enter into reaction with it with evolution of hydrogen sulphide; hence, on the addition of an alkaline hydrosulphide to solution of their salts, the corresponding hydroxides are precipitated:—

Sulphur unites with all the metals and with most of the non-metallic elements; the sulphides are therefore usually prepared directly from their elements. Two classes of sulphides corresponding to the basic and acid oxides may be distinguished, but the distinction between them is much less marked than that between the two classes of oxides. The sulphides of the non-metallic elements and the sulphides of arsenic, antimony, tin, molybdenum, tungsten, vanadium, gold, and platinum, which are soluble in solutions of alkaline hydrosulphides, belong to the class of acid sulphides, and the remaining sulphides are basic. These two classes of sulphides are capable of uniting together to form sulphur salts, just as the basic and acid oxides combine forming oxy-salts. As a rule, the sulphides and oxides of the same element have similar formulæ and correspond in their general behaviour. Occasionally there are oxides to which there are no corresponding sulphides, but more fre-

quently sulphides to which there are no corresponding oxides. All sulphides are decomposed more or less readily by hydrochloric acid gas, hydrogen sulphide and a chloride being produced, and in some cases sulphur is also liberated. Many of the sulphides which are decomposed when heated in an atmosphere of hydrochloric acid gas are little, if at all, affected by a boiling solution of the acid.

Hydrogen selenide and telluride closely resemble hydrogen sulphide in properties, but are far less stable compounds. The former has a most offensive acrid odour, impairing or even destroying the sense of smell for several hours, and producing inflammation of the eyes. Their aqueous solutions are decomposed on exposure to the air with separation of selenium and tellurium respectively; and with solutions of salts of most metals they produce precipitates of the corresponding selenhydrates or selenides and tellurhydrates or tellurides. The selenides and the tellurides, like the sulphides, may be formed by the direct combination of their elements, and are usually so prepared; in their general behaviour they resemble the corresponding sulphides.

A higher sulphide of hydrogen is known of which the composition has not yet been satisfactorily determined, owing to the difficulty of obtaining it in a pure state; but as it is obtained on adding a solution of potassium pentasulphide, K_2S_5 , to a dilute solution of hydrochloric acid, and is formed without evolution of hydrogen sulphide or separation of sulphur, it appears most probable that it is the pentasulphide H_2S_5 . It separates as an oily liquid, heavier than water, possessing a peculiar sulphurous disagreeable odour; it is soluble in water. It is a very unstable substance, undergoing decomposition into hydrogen sulphide and sulphur with great facility; this decomposition is instantaneous under the influence of substances such as finely divided platinum, gold, and charcoal. Its stability is increased by the presence of moderately strong acids, but diminished by alkalis. With an alcoholic solution of potassium hydrosulphide it furnishes potassium pentasulphide, hydrogen sulphide being evolved—

This reaction is analogous to that between sulphuric acid and potassium hydroxide:—

hydrogen pentasulphide may, in fact, be regarded as the analogue of sulphuric acid.

Sulphur, selenium, and tellurium form compounds with chlorine, bromine, and iodine, similar in composition, but differing greatly in stability.

With chlorine, sulphur forms the three compounds—

all of which are liquid. The chloride S_2Cl_2 is obtained by passing chlorine over sulphur, which is gently heated; it is a mobile reddish-yellow liquid, having a peculiar, penetrating, and most disagreeable odour. It boils without suffering decomposition at $137^\circ C$. It is slowly decomposed by water, yielding hydrogen chloride, sulphur, and thiosulphuric acid—

When saturated with chlorine at about $10^\circ C$, it is converted into the dichloride SCl_2 , but if saturated with chlorine at about $-22^\circ C$, it furnishes the tetrachloride SCl_4 . Both of these compounds are so unstable, however, that they are resolved into the lowest chloride S_2Cl_2 and chlorine when very slightly heated.

The chlorides of selenium and tellurium are also obtained by the direct action of chlorine on the elements. Two chlorides of selenium are known, Se_2Cl_2 and $SeCl_4$, the former being liquid and the latter a white crystalline solid.

Tellurium forms the two chlorides $TeCl_2$ and $TeCl_4$, both of which are solid. These chlorides of tellurium, as well as selenium tetrachloride, appear to volatilize without decomposition.

Very little is known of the bromides of sulphur and selenium, but from the observations which have been made there is no doubt that the sulphur bromides are much less stable than the chlorides; sulphur, therefore, like oxygen, appears to have less affinity for bromine than for chlorine. Tellurium furnishes two crystalline bromides, $TeBr_2$ and $TeBr_4$, both of which may be sublimed without decomposition.

The only iodide of sulphur which is known has the composition S_2I_2 , and is obtained by the direct union of its elements; it is a black crystalline solid, insoluble in water, and readily decomposes when heated. Iodides of selenium are not known with certainty, but two tellurium iodides have been prepared, TeI_2 and TeI_4 ; both are black crystalline bodies, which give off iodine when heated.

The chlorides and bromides of selenium and tellurium, like the chlorides and bromides of sulphur, are decomposed by water, but the iodides of these three elements are comparatively stable and are scarcely affected unless heated with water.

Sulphur, selenium, and tellurium burn in oxygen or air, forming the dioxides

Under certain conditions, sulphur dioxide takes up an additional atom of oxygen, and is converted into the trioxide, SO_3 ; a tellurium trioxide, TeO_3 , may also be obtained, but the corresponding oxide of selenium is not known. A third oxide of sulphur, S_2O_3 , has recently been described.

The dioxides and trioxides of sulphur, selenium, and tellurium have the property in common of forming corresponding acids when combined with water:—

These compounds differ greatly in stability and in their properties generally—the sulphur and selenium compounds being closely related, whilst the tellurium compounds are widely different from them in most respects.

Sulphur dioxide or sulphurous anhydride is a colourless gas, of pungent suffocating odour; by a pressure of three atmospheres, or a refrigerating mixture of ice and salt, it is readily condensed to a colourless mobile liquid, which boils at about $-10^\circ C$. The liquid anhydride freezes at $-76^\circ C$, forming a transparent colourless crystalline solid, which melts at about $-79^\circ C$. Water at $0^\circ C$ dissolves about 68 times its bulk of the gas, but only 32 times its bulk at 24° , forming a solution of sulphurous acid, H_2SO_3 , which is readily decomposed by heat.

Selenium dioxide or selenious anhydride is a white infusible substance, which volatilizes at a temperature below redness; its vapour condenses in snow white deliquescent prisms, which dissolve in water forming selenious acid, H_2SeO_3 .

Tellurium dioxide, however, is only very slightly soluble in water, and the solution does not exhibit an acid reaction; the attraction of this oxide for water, in fact, is so slight, that when a solution of tellurous hydrate (tellurous acid), H_2TeO_3 , is heated to about $40^\circ C$, the oxide separates. It fuses readily and volatilizes, and the fused oxide, which is a transparent, deep yellow liquid, solidifies on cooling to a white crystalline mass.

The difference in physical properties between sulphur and selenium dioxides is so great as to suggest that the

molecule of the latter is not represented by the formula SeO_2 , but that it is more complex; and although the vapour density of selenium dioxide is such as to negative this assumption for the gaseous substance, there is no evidence to show that the expression SeO_2 is the correct molecular formula for the solid oxide.

Sulphur trioxide or sulphuric anhydride is a white, highly volatile substance which dissolves in water, forming sulphuric acid, H_2SO_4 , the combination being attended with the development of so much heat that when the anhydride comes in contact with the water a violent hissing is produced, just as when a red-hot iron is plunged into water. Selenium trioxide has not been isolated, but selenic acid, H_2SeO_4 , the acid corresponding to sulphuric acid, is known, and very closely resembles the latter compound in many of its properties. Tellurium trioxide, TeO_3 , is an orange-yellow solid, insoluble in water, and therefore altogether different in properties from sulphur trioxide; moreover, the resemblance between the compound H_2TeO_4 , from which tellurium trioxide is obtained by heating to a temperature below redness, and sulphuric and selenic acids scarcely extends beyond the similarity of their formulæ, since telluric acid is nearly insoluble in water, and its solution has a metallic rather than an acid taste, and reddens litmus but slightly.

Sulphur dioxide is usually prepared for laboratory purposes by heating a metal, such as copper or mercury, with concentrated sulphuric acid; the most probable explanation of its formation in this manner appears to be that the metal acting upon the acid produces the corresponding sulphate and hydrogen, and that the latter whilst in the nascent state acts upon another portion of the acid, reducing it to sulphurous acid, which splits up into sulphur dioxide and water; thus—

We may also suppose, however, that the metal merely withdraws an atom of oxygen from the sulphuric acid, and that the oxide produced dissolves in the acid, forming a sulphate—

The kind of action represented by the first of these equations undoubtedly takes place when carbon in the form of charcoal is heated with sulphuric acid, whereby carbon dioxide, sulphur dioxide, and water are produced—

When copper is employed not only are sulphur dioxide, water, and cupric sulphate produced, but cuprous and cupric sulphides, Cu_2S and CuS , it is stated, are also formed; their production, however, is due to secondary action.

Selenium dioxide is obtained either by burning selenium in a stream of oxygen, or by evaporating a solution of selenious acid to dryness.

Sulphurous acid is always prepared by passing sulphur dioxide gas into cold water; the combination is attended with a slight elevation of temperature. Selenious acid is produced in a similar manner by dissolving the oxide in water, or by dissolving selenium in concentrated nitric acid, and evaporating to expel the excess of nitric acid. Tellurous acid may be obtained by dissolving tellurium in nitric acid of specific gravity 1.25, and pouring the solution, after the lapse of not more than a few minutes,

into water. If the precipitation be delayed for a longer time, the oxide TeO_2 is thrown down instead of the hydrate. It is best prepared by decomposing tellurium tetrachloride with water—

It is stated that anhydrous sulphurous acid, H_2SO_3 , has been obtained in crystals by cooling a saturated aqueous solution to 0°C .; a crystalline hydrate of the composition $\text{H}_2\text{SO}_3 + 8\text{H}_2\text{O}$ was obtained by Pierre by cooling to -6°C . a saturated solution through which a current of the gas was being transmitted. The solution of sulphur dioxide in water is strongly acid, and effervesces with carbonates; by passing a current of the gas through water in which metallic hydroxides or carbonates are dissolved or suspended metallic sulphites are produced. Two classes of metallic sulphites may be thus formed:—the *acid sulphites* or *bisulphites* in which one-half the hydrogen in sulphurous acid is displaced by a metal; and *normal sulphites*, in which the whole of the hydrogen is displaced. It is also possible to displace the two atoms of hydrogen in sulphurous acid by two different metals, and thus to obtain so-called double salts. The following table shows the composition of some of the sulphites, disregarding the water of crystallization which several of them contain:—

Potassium hydrogen sulphite	KHSO_3
Potassium	
Sodium hy	
Sodium sulphite	Na_2SO_3
Calcium sulphite	CaSO_3
Calcium hydrogen sulphite	$\text{CaH}_2(\text{SO}_3)_2$

The acid sulphites of barium, strontium, calcium, and magnesium, and the acid and normal sulphites of the alkali metals, are soluble in water, although only the sulphites of alkali metals are freely soluble; but most other sulphites are insoluble, and may be prepared by precipitation with an alkaline sulphite. The acid sulphites are prepared by saturating a solution of the metallic hydroxide or carbonate with sulphur dioxide gas, and then adding to it as much of the hydroxide or carbonate as it originally contained; thus—

The alkali and alkaline-earth metals are the only ones, however, which readily produce acid sulphites; in fact, the tendency to form acid salts is almost restricted to these metals in the case of all acids, and it is difficult to obtain acid salts containing heavy metals.

A solution of sulphurous acid slowly absorbs oxygen from the air and is converted into sulphuric acid; in like manner, the sulphites, particularly if in solution, become converted into sulphates on exposure to the air. All sulphites are decomposed at a red heat, either into sulphate and sulphide, or into sulphur dioxide and metallic oxide. They are also decomposed by all acids excepting carbonic and boric acids, sulphurous acid being liberated. Sulphurous acid possesses considerable bleaching powers, and is extensively employed in bleaching straw, wool, and many other articles, which would be injured by chlorine. The articles to be bleached are moistened and suspended in closed chambers in which sulphur is burnt; the sulphur dioxide produced is then absorbed by the damp goods, and their colour is discharged. The manner in which it acts is not well understood, but it appears to be by forming colourless compounds with the colouring matters; it does not, like chlorine, decompose colouring matters, for

the colour may usually be restored by acids or alkalis. The reproduction of the yellow colour of new flannel, when it is washed with an alkaline soap for the first time, is an illustration of this. Sulphurous acid is also a powerful antiseptic, and is highly valuable as a disinfecting agent.

Selenious acid is deposited from a hot aqueous solution on slow cooling in colourless prismatic crystals like salt-petre. It closely resembles sulphurous acid in properties, and like it furnishes *acid selenites*, such as potassium hydrogen selenite, KHSeO_3 , and *normal selenites*, such as potassium selenite, K_2SeO_3 , but it also forms so-called *hyperacid* salts with the alkali metals, e.g., $\text{HKSeO}_3 + \text{H}_2\text{SeO}_3$. The selenites of alkali metals are soluble in water, but the other selenites are insoluble.

Tellurous hydrate, prepared by decomposing tellurium tetrachloride with water, is a bulky precipitate, which, when dried over sulphuric acid, forms a light white earthy powder, having a bitter metallic taste. It is only slightly soluble in water, but dissolves in alkalis and alkaline carbonates. With the alkali metals tellurous acid forms three classes of salts corresponding to the three classes of selenites, of which the following are examples—

With the alkaline earth metals tellurous acid forms normal salts, and also certain peculiar salts, such as BaTe_2O_5 or $\text{BaTeO}_3 + \text{TeO}_2$, and BaTe_4O_9 or $\text{BaTeO}_3 + 3\text{TeO}_2$. With the heavy metals it appears to form only normal salts. The tellurites of alkali metals are soluble in water, but those of other metals are difficultly soluble or insoluble.

In its oxides, therefore, it will be evident tellurium differs widely from selenium and sulphur, but it much resembles metals like bismuth and antimony, since it forms salts with acids. Thus, a tellurium sulphate of the composition $\text{Te}(\text{SO}_4)_2$, it is stated, is formed by dissolving tellurium in concentrated sulphuric acid. Tellurous hydrate also dissolves readily in acids; the solution in hydrochloric acid probably contains either tellurium chloride, TeCl_4 , or a compound intermediate in composition between tellurium chloride and tellurium hydroxide, $\text{Te}(\text{OH})_4$, formed from the latter by the partial displacement of the OH groups by chlorine; when it is dissolved in oxy-acids, apparently salts are formed in which the group TeO displaces hydrogen, corresponding to the antimony salts in which the radicle SbO displaces hydrogen.

Sulphurous acid, on account of its tendency to form sulphuric acid, has considerable power as a reducing agent. Thus iodine and sulphurous acid, in presence of a large quantity of water, yield hydriodic and sulphuric acid—

With chlorine and bromine similar reactions occur still more readily. On this account, sulphurous acid is largely employed as an "antichlor" to remove the excess of chlorine from articles bleached with bleaching powder. When solutions of sulphurous and selenious acid are mixed, the latter is reduced, especially on warming, and red amorphous selenium precipitated; similarly, a black precipitate of tellurium is formed on warming a solution containing tellurous and sulphurous acids. But these acids also readily part with at least a portion of their oxygen. For instance, when hydrogen sulphide gas is passed into a solution of sulphurous acid, sulphur is deposited, and the solution contains pentathionic acid—

When a solution of selenious acid is similarly treated, a precipitate is thrown down, which apparently consists

chiefly of selenium sulphide, SeS_2 , mixed with a lower sulphide and free sulphur. Solutions of tellurous hydrate when thus treated furnish a brown precipitate of tellurium sulphide.

Sulphur Trioxide, SO_3 .

Dry sulphur dioxide gas and oxygen readily combine when the mixture is passed over gently heated platinum black or platinized pumice, forming sulphur trioxide or sulphuric anhydride, SO_3 . This compound may be obtained from sulphuric acid by distilling it with phosphoric anhydride:—

It is usually prepared from Nordhausen sulphuric acid, which gives off sulphur trioxide when gently heated, ordinary sulphuric acid remaining behind.

Sulphur trioxide usually crystallizes in white slender needles, but it exists in two modifications. Thus, when the liquid oxide is cooled, it solidifies at 16°C . in long colourless prisms, which melt at the same temperature; but if kept at temperatures below 25° , it changes into a mass of fine white needles. This second modification gradually liquefies at temperatures above 50° , and again passes into the first modification; it dissolves with extreme slowness in sulphuric acid, whereas the liquid oxide is miscible in all proportions with the acid. Liquid sulphuric anhydride undergoes very great expansion by heat, its mean coefficient of expansion between 25° and 45°C . being $\cdot 0027$ for 1°C .; it is quite colourless when pure. Sulphur trioxide very readily parts with one of its atoms of oxygen, converting phosphorus trichloride, for example, into phosphorus oxytrichloride—

This reaction takes place when the substances are merely mixed together, although a strong red heat is necessary in order to resolve the trioxide into sulphur dioxide and oxygen.

When finely divided sulphur is added in small quantities to liquid sulphuric anhydride, drops of a deep blue colour sink to the bottom and solidify immediately. These consist of the compound S_2O_3 . The temperature during the operation must be kept at 15°C ., for if it is lower the anhydride does not remain liquid, and if higher the substance decomposes. When about a gramme of sulphur has been added the anhydride is poured off, and the solid residue freed from any that remains by a gentle heat. A bluish-green crystalline mass is thus obtained, which decomposes at ordinary temperatures, giving off sulphur dioxide, and leaving sulphur; water immediately decomposes it, forming sulphuric, sulphurous, and probably thio-sulphuric acids. The corresponding selenium compound, SeSO_2 , may be prepared in a similar manner.

Sulphuric Acid, H_2SO_4 .

Of all chemical compounds this is probably the most important, on account of its numerous practical applications, and enormous quantities of it are now manufactured. The method employed consists essentially in oxidizing sulphurous acid by atmospheric oxygen, which is accomplished with the aid of nitric oxide gas in the following manner. Sulphur dioxide gas is prepared by burning sulphur, or iron pyrites, FeS_2 , in a properly constructed furnace, sulphur being always employed when the purest qualities of acid are required, and this gas is conveyed into a large leaden chamber, into which steam and air are also continuously admitted. At the back of the furnace in which the sulphur is burnt, a small vessel is placed containing sodium

nitrate and sulphuric acid, which continue to generate nitric acid for some time; thus—

The exact changes which occur among the various substances thus introduced into the chambers are but imperfectly understood; the nitric acid, however, is apparently decomposed by the sulphurous acid in such a manner that finally nitric oxide is produced—

But nitric oxide combines directly with oxygen at ordinary temperatures, forming the oxides N_2O_3 and N_2O_4 , and it is generally supposed that the nitric oxide thus formed acts as a carrier of oxygen,—that on coming in contact with the oxygen of the air introduced into the chamber, it is converted into a higher oxide, which, however, is no sooner produced than it is reduced again to nitric oxide by the sulphurous acid, which is oxidized to sulphuric acid; supposing the oxide formed to be nitric peroxide, we may represent the change by the following simple equation:—

The nitric oxide again absorbs oxygen to form the higher oxide, which again enters into reaction with sulphur dioxide and water, with liberation of nitric oxide, and so on continuously. Theoretically, therefore, a limited quantity of nitric oxide should suffice to produce an indefinitely large amount of sulphuric acid, but practically this is not the case, chiefly owing to the loss occasioned by the dissolution of a certain quantity in the sulphuric acid which collects on the floor of the chambers; a certain amount also escapes from the chambers with the nitrogen of the air, but this is usually absorbed by passing the escaping vapours through a tower filled with pieces of coke, kept moistened with sulphuric acid, or over which water is constantly pouring; when acid is employed it is afterwards pumped into a similar scrubber, and deprived of its nitric oxide gas by means of the sulphur dioxide gas from the burning sulphur or pyrites, and when water is used it is pumped into, and distributed on the floors of, the leaden chambers.

In practice the amount of sulphuric acid produced usually approximates very closely to the theoretical quantity.

It is beyond question that the reactions which occur in the formation of sulphuric acid are not all of the simple character represented by the equations above given. Thus, the formation of nitric oxide from nitric acid is probably the final result of three distinct reactions. In the first place, from the sulphur dioxide and nitric acid a compound which is known as the lead chamber crystals, on account of its forming crystals, is probably produced; thus—

This compound, it will be observed, is very closely related to sulphuric acid, and may be regarded as formed from it by the displacement of one of the OH groups by the group NO_2 . It is decomposed by water, yielding sulphuric and nitrous acids:—

From the nitrous acid thus formed nitric oxide may be produced in two ways,—either by its spontaneous decomposition in accordance with the equation

or by the action of sulphur dioxide—

The latter reaction appears to be the more probable on account of the large amount of sulphur dioxide present, but it is not unlikely that both occur.

With regard to the part which the nitric oxide plays in the conversion of sulphurous into sulphuric acid, it is highly probable that, by the conjoint action of the oxygen and water present, it is converted into nitrous acid, from which nitric oxide is reproduced by the action of the sulphur dioxide in the manner above pointed out—

If this be the case, nitrous acid is the active agent in the conversion of sulphur dioxide into sulphuric acid. It is known to effect the oxidation of sulphur dioxide with the greatest readiness, whereas dilute nitric acid has very little action. On this account, it is probable also that the nitric oxide is not converted into the peroxide, as sometimes is supposed, and that the latter is the active agent in the formation of sulphuric acid, for our general experience appears to warrant the conclusion that, as sulphur dioxide enters so readily into reaction with nitrous acid, this acid would be produced from the nitric oxide almost entirely to the exclusion of other oxidation products. Moreover, nitric peroxide in presence of water forms nitrous and nitric acids: $\text{N}_2\text{O}_4 + \text{H}_2\text{O} = \text{HNO}_2 + \text{HNO}_3$; so that, even supposing that the nitric oxide is converted into nitric peroxide, the formation of sulphuric acid would still in a large measure be due to the action of nitrous acid. Although sulphur dioxide acts very slowly on dilute nitric acid, it readily reduces it to nitric oxide in presence of moderately concentrated sulphuric acid; hence any nitric acid formed in the process, when carried down to the floor of the chamber and mixed with the moderately concentrated sulphuric acid there collected, would also undergo reduction by the sulphur dioxide.

The acid from the leaden chambers has generally a specific gravity of about 1.55; by concentration in shallow leaden pans this is raised to above 1.7. The further concentration is effected in glass or platinum retorts. The commercial acid, known as oil of vitriol, has a specific gravity of about 1.84; it is frequently of a more or less brown colour from the presence of organic matter, and always contains lead. Other impurities, such as arsenic and nitrous or nitric acid, are not unfrequently present.

Pure sulphuric acid, H_2SO_4 , is an oily, colourless, inodorous liquid, of specific gravity 1.842; it solidifies at -35°C . It cannot be distilled unchanged, and when heated gives off the anhydride until a liquid remains containing about 1.5 per cent. of water and 98.5 per cent. of sulphuric acid, which boils at 338°C ; acid of this strength may always be obtained by boiling down acid of any other degree of concentration. When the acid is vaporized, dissociation takes place very rapidly, the vapour at temperatures above 400°C . consisting entirely of a mixture of water and sulphuric anhydride. Sulphuric acid chars most organic substances containing oxygen and hydrogen on account of its great affinity for water, causing the separation of these elements in the form of water and the liberation of carbon; when exposed to moist air it will even double its weight in the course of a few days, and on this account it is much employed as a desiccating agent. Much heat is developed when it is mixed with water, as will be evident from the following table, which represents the amounts of heat developed on mixing one molecule of the acid (98 grammes) with n molecules of water at about 18°C ., according to Thomsen's determinations:—

No. of molecules of water added.	Units of heat developed.	No. of molecules of water added.	Units of heat developed.
1	6,272	99	16,850
2	9,301	199	17,056
3	11,108	499	17,304
5	13,082	799	17,632
9	14,940	1599	17,848
19	16,248	∞	17,994
49	16,676		

The last number in the table represents the amount of heat which, according to calculation, would be developed on mixing a molecule of sulphuric acid with an infinitely large quantity of water. It will be seen that the addition of the first two molecules is accompanied with the development of an amount of heat equal to half the entire amount developed on adding an excess of water; this appears to be accounted for by the formation of definite compounds of sulphuric acid with water. The first of these *hydrates*, $\text{H}_2\text{SO}_4 + \text{H}_2\text{O}$, may be obtained crystallized in colourless six-sided prisms, by cooling a mixture of the acid and water in these proportions to about 8°C .; it boils at $205^\circ\text{--}210^\circ \text{C}$., and may be produced by evaporating any more dilute sulphuric acid at 205°C . until it ceases to lose water. The second hydrate, $\text{H}_2\text{SO}_4 + 2\text{H}_2\text{O}$, may, in a similar manner, be obtained by evaporating any more dilute acid at 100°C . until it ceases to lose water; it boils at 193°C . The specific gravity of the first hydrate is 1.78, and that of the second 1.62; when water is added to the acid in the proportions to form the latter, the maximum condensation (about 8 per cent.) is observed which occurs on mixing these substances.

Further evidence in support of the view that sulphuric acid forms definite compounds with water which may be regarded as distinct acids is afforded by its behaviour on neutralization, by the persistent manner in which many sulphates retain one or two molecules of water, and by the existence of so-called basic sulphates. Thus, when it is neutralized by sodium hydroxide, considerably less heat is developed by the first than by the second molecule of hydroxide; this behaviour does not appear remarkable if it be supposed that it exists in solution in combination with water, and that, therefore, as in the case of periodic acid, not only is hydrogen displaced by sodium on the addition of the hydroxide, but the elements of one or more molecules of water are also separated, the latter being an operation which necessarily would involve the expenditure of energy, as the combination of the acid with water is attended with the development of heat (see page 488).

By displacing one-half the hydrogen in sulphuric acid by metals *acid sulphates* are formed, and *normal sulphates* are produced by displacing the whole of the hydrogen. Many of the normal sulphates crystallize with the same number of molecules of water, and are isomorphous, as, for example—

Magnesium sulphate	$\text{MgSO}_4, 7\text{H}_2\text{O}$
Zinc "	$\text{ZnSO}_4, 7\text{H}_2\text{O}$
Iron "	$\text{FeSO}_4, 7\text{H}_2\text{O}$
Nickel "	$\text{NiSO}_4, 7\text{H}_2\text{O}$
Cobalt "	$\text{CoSO}_4, 7\text{H}_2\text{O}$

Five of the seven molecules of water are removed with facility from these salts, but the sixth is less readily removed, especially from magnesium sulphate, and they are not deprived of the seventh unless heated to $200^\circ\text{--}300^\circ \text{C}$. Copper, cadmium, and manganese sulphates behave similarly, and are only with difficulty deprived of the last molecule of water. The last molecule retained with such persistency by these salts was termed, by Graham, *water of constitution*, to distinguish it from water of crystallization. In the present state of our knowledge it is impossible absolutely to define the meaning of those terms, or even to

say that there is an absolute difference between the so-called water of constitution and water of crystallization, and not merely one of degree; but since we have independent evidence tending to prove the existence of distinct acids formed by the combination of sulphuric acid with water, we may conveniently regard the above-mentioned salts as derived from these acids. Magnesium sulphate, for example, we may regard as the normal magnesium salt of the acid H_2SO_6 , crystallized with five molecules of water. It will be evident that such salts as this bear a relation to the acid from which they are regarded as derived similar to that which the normal periodates bear to crystalline periodic acid, H_5IO_6 ; indeed, a very considerable general resemblance may be traced between the periodates and the sulphates. Thus, the sulphates of potassium, K_2SO_4 , and of silver, Ag_2SO_4 , separate from aqueous solution in anhydrous crystals; and sodium sulphate, Na_2SO_4 , is also deposited in the anhydrous state at temperatures above 34°C .; it is only with metals such as magnesium, zinc, and copper, that salts are obtained which may be regarded as derived from the acids H_4SO_6 or H_6SO_6 . Similarly, the periodates KIO_4 , NaIO_4 , and AgIO_4 , derived from the at present hypothetical acid HIO_4 , are readily produced, but with other metals chiefly salts derived from the acid H_5IO_6 are obtained.

But that these hydrates of sulphuric acid are distinct acids derives its most important confirmation from the existence of the so-called basic sulphates, such as Zn_3SO_5 or $\text{ZnSO}_4 + \text{ZnO}$, Hg_3SO_6 or $\text{HgSO}_4 + 2\text{HgO}$, and $\text{Cu}_3\text{SO}_6 + 3\text{H}_2\text{O}$ or $\text{CuSO}_4 + 2\text{CuO} + 3\text{H}_2\text{O}$; these salts are strictly comparable with the basic periodates.

A large number of double and mixed salts formed by the union of two or more sulphates are known. Thus, magnesium sulphate and the isomorphous sulphates form isomorphous double salts with potassium, sodium and ammonium sulphates, which crystallize with six molecules of water, and which usually are therefore regarded as formed by the displacement of the molecule of so-called water of constitution by the alkaline sulphate—

Magnesium potassium sulphate.....	$\text{MgK}_2(\text{SO}_4)_2, 6\text{H}_2\text{O}$
Zinc " "	$\text{ZnK}_2(\text{SO}_4)_2, 6\text{H}_2\text{O}$
Iron " "	$\text{FeK}_2(\text{SO}_4)_2, 6\text{H}_2\text{O}$
Nickel " "	$\text{NiK}_2(\text{SO}_4)_2, 6\text{H}_2\text{O}$
Cobalt " "	$\text{CoK}_2(\text{SO}_4)_2, 6\text{H}_2\text{O}$

It has already been pointed out that sulphuric acid may be regarded as a compound of the dyad radicle SO_2 with the monad radicle OH , or as $(\text{SO}_2)(\text{OH})_2$, this view of its "constitution" being chiefly founded on its behaviour with the chlorides of phosphorus. Thus, by the action of phosphorus pentachloride on sulphuric acid, an atom of oxygen and an atom of hydrogen, in other words, the group OH , are displaced by a single atom of chlorine—

Although evidence of the existence of a second OH group in sulphuric acid cannot be obtained in a similar manner by the continued action of the phosphorus pentachloride, it is afforded by the behaviour of the compound SO_2Cl_2 , produced by the direct union of chlorine and sulphur dioxide with water, which successively converts it into the compound $\text{HO.SO}_2.\text{Cl}$ and sulphuric acid—

Sulphuric chloride, SO_2Cl_2 , and sulphuric chlorhydrate, $\text{SO}_2(\text{OH})\text{Cl}$, are both colourless liquids; the former boils at about 70°C ., and the latter at 158°C . Sulphuric chlorhydrate may be formed by the direct combination of hydrogen chloride with sulphuric anhydride, and when heated in closed vessels to 170°C ., it furnishes sulphuric chloride and sulphuric acid:—

Sulphuric acid enters into reaction with a large number of hydrogenized carbon compounds in such a manner that water is formed and hydrogen displaced by the monad group $\text{SO}_2 \cdot \text{OH}$; for example—

The *sulphonic acids*, as the compounds thus produced are termed, are powerful monobasic acids. But the action may proceed further, both OH groups in sulphuric acid being displaced by monad compound radicles, in which case neutral bodies called *sulphones* are formed; thus—

Selenic Acid, H_2SeO_4 .

This acid may be obtained by oxidizing selenious acid by the action of chlorine, or bromine, and water—

It is a transparent colourless liquid, which in the most concentrated state boils at 280°C ., and has a specific gravity of 2.6. In this state it is not quite pure selenic acid, but contains a little water, which cannot be driven off without decomposing the acid into selenium dioxide, oxygen, and water. Selenic acid resembles sulphuric acid in many of its properties, being very hygroscopic, and when it is added to water a considerable amount of heat is developed. It is reduced to selenious acid when boiled with hydrochloric acid—

but it is not decomposed by the hydrogen produced when zinc or iron is dissolved in its solution. Like sulphuric acid it precipitates barium salts, even in presence of other mineral acids.

The selenates or salts produced by displacing the hydrogen in selenic acid by metals correspond in composition, and also very closely in their properties, to the sulphates, with which they are isomorphous.

Telluric Acid, H_2TeO_4 .

The potassium salt of this acid is obtained by fusing tellurium or tellurous oxide with potassium nitrate. From this salt barium tellurate may be prepared by precipitating its solution with a barium salt, and the acid is produced by decomposing barium tellurate with sulphuric acid.

Telluric acid crystallizes from water in large prisms of the composition $\text{H}_2\text{TeO}_4 \cdot 2\text{H}_2\text{O}$. This hydrate has a metallic taste, and reddens litmus slightly. It dissolves slowly in cold water, but freely in boiling water. It loses its water of crystallization at a little above 100°C . The compound H_2TeO_4 is nearly insoluble in cold water, but dissolves on boiling; when heated to a temperature below redness it furnishes the oxide TeO_3 . It is reduced to tellurous acid by boiling with hydrochloric acid, and it is also decomposed by sulphurous acid, which is without action on selenic acid, with precipitation of tellurium.

In addition to acid and normal tellurates, such as KHTeO_4 and K_2TeO_4 , and hyperacid tellurates, of which the salt $\text{KHTeO}_4 + \text{H}_2\text{TeO}_4$ is an example, telluric acid also furnishes so-called di- and tetra-tellurates, such as $(\text{NH}_4)_2\text{Te}_2\text{O}_7$ and $(\text{NH}_4)_4\text{Te}_4\text{O}_{13}$ or $(\text{NH}_4)_2\text{TeO}_4 + 3\text{TeO}_3$, and basic tellurates, such as Ag_6TeO_6 and $\text{Ag}_3\text{Te}_2\text{O}_9$. The ditellurates may be regarded as salts of the acid $\text{H}_2\text{Te}_2\text{O}_7$, analogous to anhydrosulphuric acid, and the basic salt Ag_6TeO_6 as formed from the hydrate H_6TeO_6 or $\text{H}_2\text{TeO}_4 + 2\text{H}_2\text{O}$; whilst salts such as $\text{Ag}_3\text{Te}_2\text{O}_9$ are apparently derivatives of an acid formed by the withdrawal of the elements of three molecules of water from two molecules of the acid H_6TeO_6 .

Other Acids of Sulphur.

In addition to sulphurous and sulphuric acids, a number of acids, more or less closely related to them, may be obtained. The following is a complete list of the known acids of sulphur:—

Hyposulphurous acid	H_2SO_2
Sulphurous acid	H_2SO_3
Sulphuric acid	H_2SO_4
Thiosulphuric acid	$\text{H}_2\text{S}_2\text{O}_3$
Anhydrosulphuric acid	$\text{H}_2\text{S}_2\text{O}_7$
Dithionic acid	$\text{H}_2\text{S}_2\text{O}_6$
Trithionic acid	$\text{H}_2\text{S}_3\text{O}_6$
Tetrathionic acid	$\text{H}_2\text{S}_4\text{O}_6$
Pentathionic acid	$\text{H}_2\text{S}_5\text{O}_6$

Hyposulphurous Acid.—This acid is obtained by the action of zinc on a solution of sulphurous acid, which dissolves the metal, forming zinc sulphite; the hydrogen, which is the accessory product of this reaction, is not evolved, however, but reduces a portion of the acid, forming hyposulphurous acid; thus—

The solution thus obtained is very unstable, and rapidly decomposes with separation of sulphur. Sodium hypsulphite, NaHSO_2 , is a more stable substance, and is produced in a similar manner by the action of zinc on a solution of sodium hydrogen sulphite. This salt crystallizes in slender colourless needles; it is soluble in water, but insoluble in alcohol. When exposed to the air in a moist state it becomes very hot, and is converted by oxidation into hydrogen sodium sulphite, but in the dry state it is not affected by oxygen. The remarkable observation has been made, however, that when a solution of sodium hypsulphite is oxidized by free oxygen, that is to say, when water saturated with oxygen is added to a solution of the hypsulphite, only one-half the oxygen is employed in causing the conversion of the hypsulphite into the sulphite, the remaining half becoming affixed to water, forming hydrogen dioxide; the reaction may be expressed by the following equation—

Hypsulphurous acid has a much greater decolorizing and reducing power than sulphurous acid; it immediately reduces the metals from mercury and silver salts, and it precipitates copper hydride, Cu_2H_2 , from a solution of copper sulphate.

Thiosulphuric Acid, $\text{H}_2\text{S}_2\text{O}_3$.

This acid is formed from sulphurous acid by combining it with sulphur; thus, when a solution of sodium sulphite is digested with sulphur, sodium thiosulphate is produced—

It will be obvious that this reaction is precisely analogous to that which occurs when sodium sulphite is converted into sodium sulphate by the action of oxygen.

Thiosulphuric acid cannot be isolated, on account of its instability, and when an acid—hydrochloric acid, for example—is added to a solution of a thiosulphate, the thiosulphuric acid which is produced rapidly decomposes into sulphur and sulphurous acid: $\text{H}_2\text{S}_2\text{O}_3 = \text{H}_2\text{SO}_3 + \text{S}$. The thiosulphates of alkali and alkaline earth metals are crystalline and soluble in water, and are fairly stable salts; the thiosulphates of the heavy metals, however, which are precipitated on the addition of solutions of

metallic salts to a solution of sodium thiosulphate, are very unstable, and rapidly decompose into a metallic sulphide and sulphuric acid, thus—

Sodium thiosulphate is largely employed in photography for the purpose of dissolving the chloride, bromide, and iodide of silver. These salts are readily soluble in a solution of the thiosulphate until they are exposed to light, when they become insoluble. If, therefore, a sheet of paper coated with one of these silver salts be exposed to light under an object which is in part transparent and in part opaque, such as a piece of lace, for example, the silver salt is rendered insoluble in those parts upon which the light has fallen, and by then immersing the paper in a solution of sodium thiosulphate the unaltered silver salt is removed, and the picture is thus "fixed." The solvent power of the thiosulphate is due to the formation of a soluble silver sodium thiosulphate—

many other metallic salts insoluble in water are dissolved by a solution of sodium thiosulphate, probably also in consequence of the formation of similar mixed salts.

Anhydrosulphuric Acid, H₂S₂O₇.

This acid is obtained by dissolving sulphuric anhydride in sulphuric acid in the requisite proportions: $\text{H}_2\text{SO}_4 + \text{SO}_3 = \text{H}_2\text{S}_2\text{O}_7$. It crystallizes in large colourless transparent prisms. When gently heated it is decomposed into sulphuric anhydride, which distils over, and sulphuric acid, which remains. Water dissolves it, forming sulphuric acid.

The so-called Nordhausen or fuming sulphuric acid consists chiefly of this acid. It is prepared at Nordhausen, in Saxony, by distilling an impure ferric sulphate, $\text{Fe}_2(\text{SO}_4)_3$, obtained by exposing ferrous sulphate, FeSO_4 , to a moderate heat in contact with the air,—the distillate, consisting chiefly of sulphuric anhydride, being received in sulphuric acid. This acid readily dissolves many hydrogenized carbon compounds which are only with difficulty acted upon by ordinary sulphuric acid, converting them into sulphonic acids; it is employed on this account to dissolve indigo, and in the preparation of anthraquinonedisulphonic acid, from which alizarin is artificially produced.

Salts of this acid, such as $\text{Na}_2\text{S}_2\text{O}_7$, $\text{Ag}_2\text{S}_2\text{O}_7$, BaS_2O_7 , are obtained by combining the corresponding normal sulphates with sulphuric anhydride; water decomposes them, forming corresponding acid sulphates. The acid salt, KHS_2O_7 , or hydrogen potassium anhydrosulphate, is obtained by dissolving the normal salt in anhydrosulphuric acid; it crystallizes in prisms.

The chloride of anhydrosulphuric acid, $\text{S}_2\text{O}_7\text{Cl}_2$, is produced by the action of sulphuric anhydride on many chlorinated compounds, thus—

It is a colourless oily liquid, of specific gravity 1.829 at 18° C., and boils at 146° C. In contact with water it decomposes slowly and noiselessly, forming sulphuric and hydrochloric acids, and is thus distinguished from sulphuric chlorhydrate, $\text{SO}_2(\text{OH})\text{Cl}$, which is rapidly decomposed with almost explosive violence when thrown into water.

The lead chamber crystals (p. 504), when heated, furnish a magnificently crystalline body, which is also a derivative of anhydrosulphuric acid—

it distils at about 360° C. without decomposing.

Dithionic Acid, H₂S₂O₆.

The manganese salt of this acid is obtained by the action of a solution of sulphurous acid on manganese dioxide—

This salt may be converted into the barium salt by treatment with barium hydroxide, and from a solution of the barium salt the acid is produced by adding exactly sufficient sulphuric acid to precipitate the barium. By concentrating the solution in a vacuum over sulphuric acid it may be obtained of specific gravity 1.347, but on further concentration the acid is resolved into sulphurous acid and sulphur dioxide—

A dilute solution decomposes in a similar manner when heated. In contact with the air dithionic acid is slowly oxidized to sulphuric acid.

The dithionates produced by decomposing barium dithionate, BaS_2O_6 , with the corresponding sulphates, are all soluble in water and crystallize well. They exhibit considerable stability, but when heated are more or less readily converted into the corresponding normal sulphate and sulphur dioxide.

Trithionic Acid, H₂S₃O₆.

Potassium trithionato is produced, together with potassium thiosulphate, when a saturated solution of hydrogen-potassium sulphite is gently heated with sulphur; it is not improbable that the thiosulphate is a secondary product, formed by the action of hydrogen sulphide resulting from the action of the sulphur on the hydrogen potassium sulphite—

Trithionic acid may be obtained from a concentrated solution of the potassium salt by precipitating the potassium by hydrofluosilicic acid. The solution has a sour and somewhat bitter taste, and is inodorous; it is permanent in a dilute state only, and on concentrating it in a vacuum over sulphuric acid it begins to decompose, even at 0° C., sulphur dioxide being evolved, and sulphur deposited, while sulphuric acid remains in solution. The salts of trithionic acid are but little known; they are extremely unstable, and even when boiled with water are decomposed and converted into sulphates, with evolution of sulphur dioxide and deposition of sulphur—

Tetrathionic Acid, H₂S₄O₆.

The salts of this acid are produced by the action of iodine on thiosulphates; for example—

The acid may be prepared from the barium salt by double decomposition with sulphuric acid. A dilute solution may be boiled without decomposing; but a concentrated solution is decomposed when heated, yielding sulphur, and sulphurous and sulphuric acids. Its salts are all soluble in water, and are much more stable than the trithionates, but for the most part their solutions cannot be evaporated without decomposition.

Pentathionic Acid, H₂S₅O₆.

A solution of this acid is obtained by alternately passing sulphur dioxide and hydrogen sulphide gases through water—

the solution may be concentrated by a gentle heat till it attains a specific gravity of 1.25-1.3, and may then be further concentrated in a vacuum to the specific gravity of about 1.6. The solution is colourless and inodorous, and has a strongly acid taste; it may be preserved unchanged at ordinary temperatures, but on heating a concentrated solution of the acid, hydrogen sulphide and sulphur dioxide are evolved, sulphur is deposited, and sulphuric acid remains.

The salts of pentathionic acid are so unstable that it is difficult to obtain them in the solid state. In their formation from the acid there is a great tendency for the fifth atom of sulphur to be separated, tetrathionates being produced, which have greater stability, and sometimes two atoms of sulphur are given up and trithionates are formed.

A number of the reactions-involved in the formation of various sulphur compounds, and also of a few selenium and tellurium compounds, have been submitted to thermochemical investigation by Thomsen. The results deduced from his experiments are given in the following table:—

Reaction.	Units of heat developed or absorbed.	Remarks.
<i>Sulphur.</i>

<i>Tellurium.</i>		
Tellurous acid	(Te, O ₂ , H ₂ O)	81,190
Telluric acid	(TeO ₂ Aq, O).....	25,850
acid	(Te, O ₃ , Aq).....	107,040

The number 4510 for the reaction S, H₂ applies strictly only to sulphur in the state in which it separates when hydrogen sulphide is decomposed by iodine, and would require a small correction to make it applicable to rhombic sulphur.

On comparing the numbers representing the amounts of heat developed in the formation of sulphurous and sulphuric acids and of the corresponding selenium and tellurium compounds, thus—

	Sulphur.	Selenium.	Tellurium.
	R = S	R = Se	R = Te
R, O ₂ , Aq.....	78,770	56,790	81,190
R, O ₃ , Aq.....	142,400	77,240	107,040
RO ₂ Aq, O	63,630	20,450	25,850

it will be evident that the affinity of selenium to oxygen, as measured by the heat developed, is less than that of sulphur to oxygen, and also less than that of tellurium to oxygen. In this respect, therefore, sulphur, selenium, and tellurium form a series corresponding to that in which chlorine, bromine, and iodine may be arranged. Bromine, we have seen, is intermediate in its properties between chlorine and iodine, and its atomic weight is also almost the mean of the atomic weights of these two elements, and its affinity to oxygen is less than that of either chlorine or iodine; the atomic weight of selenium, which is intermediate in its properties between sulphur and tellurium, is also nearly the mean of the atomic weights of these elements.

Constitution of the Sulphur Compounds.

The constitution of the compounds of sulphur with monad elements may be readily deduced; thus, the only formulæ by which the chlorides of sulphur can be represented graphically are as follows:—

But the constitution of each of the oxides of sulphur may be expressed in two ways, thus—

In like manner, two corresponding formulæ may be assigned to each of the acids formed by combining these oxides with the elements of a molecule of water. Sulphuric acid, for instance, may be represented by either of the following formulæ—

But as compounds in which two or more atoms of oxygen are directly united together (for example, hydrogen dioxide, the higher oxides of chlorine, and chloric acid, as to the constitution of which there can be little doubt as they contain only monad elements associated with oxygen) readily decompose with separation of oxygen, the first of these formulæ for sulphuric acid appears improbable on account of the stability of the acid and of most of the

compounds derived from it. If, however, the second formula be adopted, it follows that the formula which represents the three atoms of oxygen in the trioxide as directly associated with the sulphur atom is the more probable. It is probable that sulphur dioxide and sulphurous acid are analogous in constitution to sulphur trioxide and sulphuric acid, and from the manner in which hyposulphurous acid is formed from sulphurous acid we may infer that it has the constitution represented by the second of the following formulae—

The following formulae are the most probable expressions of the constitution of the remaining acids of sulphur; the constitution of the SO_2 group is the same as in sulphuric acid and the dots are used instead of lines—

We have previously pointed out (p. 474) the value which is to be attached to constitutional formulae such as are here assigned to the sulphur compounds.

NITROGEN.

Symbol, N; Atomic wt., 14; Molecular wt., 28.

Nitrogen in the free state constitutes about four-fifths by volume of the atmosphere; in combination it occurs in nitrates and ammoniacal salts, and it enters into the composition of all animal and vegetable tissues.

It is best obtained from air by removing the oxygen by means of copper heated to redness; the air being first led through a solution of potassic hydrate to free it from carbon dioxide, and then through concentrated sulphuric acid to remove moisture, and when thus purified, passed through a tube containing metallic copper heated to dull redness. By passing a mixture of air and ammonia over heated copper, the copper oxide is reduced as fast as it is formed, and a short length of copper suffices for the preparation of an indefinite quantity of nitrogen; thus—

The supply of air is easily regulated, as an excess shows itself by tarnishing the surface of the copper.

The easiest method of obtaining pure nitrogen is to heat a solution of ammonium nitrate, which splits up into nitrogen and water: $\text{NO}_2\text{NH}_4 = \text{N}_2 + 2\text{H}_2\text{O}$. But as this salt is difficult to prepare, it is better to substitute for it a mixture of potassium nitrate and ammonium chloride, which together produce ammonium nitrate and potassium chloride—

Nitrogen is a colourless, inodorous, tasteless, incondensable gas; it is only very sparingly soluble in water, 100 volumes of water at 15°C . dissolving about one and a half volumes of nitrogen. It is incombustible, and does not support the combustion of ordinary combustibles; it is not poisonous, but an animal immersed in it dies sharply for want of oxygen. Nitrogen evinces but little tendency to enter into reaction with other elements; titanium, tungsten, vanadium, and probably a few others combine directly with it, however, but its compounds are mostly produced by indirect means.

Atmospheric air consists not only of nitrogen and oxygen, which are its chief constituents, but besides these contains carbon dioxide, ammonia, water vapour, &c.; solid substances, such as common salt, are also frequently held in suspension by it, especially in the neighbourhood of the sea and of towns. Air from which all other constituents are removed does not always exhibit the same composition, however, although the variations are very slight; usually in pure air the proportion of oxygen is from 20.9 to 21 volumes in 100 of air, but considerably less oxygen has been found in air from confined spaces and in a few samples collected in warm countries. Full information on this subject may be obtained from Dr Angus Smith's work on Air and Rain.

The fact, however, that oxygen and nitrogen are not always contained in air in the same proportions is alone a sufficient proof that they are not combined, but only mixed together, as the constituents of a compound always occur in invariable proportions. This conclusion is confirmed in many ways. Thus, the proportions in which nitrogen and oxygen are present in air are not those of their atomic weights, nor do they bear any simple relation to them. We know also that when gases enter into reaction to form new compounds their combination is usually attended with an alteration of volume, and heat is developed; moreover, the resulting compound possesses properties which differ strikingly from those of its constituents. But when oxygen and nitrogen are mixed together in the proportions in which they are present in air, neither is any alteration in volume observed, nor is heat developed; and the properties of the resulting mixture are precisely those of air, and just such as we should expect to result from the admixture of a gas which very readily supports combustion with one in which combustion is impossible. Again, were air a compound it should dissolve in water as such, or in other words, the proportion of oxygen and nitrogen in the dissolved air should be the same as in the undissolved air; but if a mixture, the more soluble constituent should dissolve the more readily, and relatively more oxygen than nitrogen should dissolve, since oxygen is more soluble than nitrogen. Experiment proves that the latter is the case, for if water which has been recently boiled to free it from dissolved gases and allowed to cool out of contact with air be shaken with air, and the dissolved air be then expelled from it by heating, and collected, it is found on analysis to contain 32 instead of only 21 per cent. by volume of oxygen. Lastly, we have seen (p. 481) that the oxygen may be to a great extent separated from the nitrogen by a mechanical process by submitting air to filtration through a thin caoutchouc membrane.

It is impossible for animals to live for any length of time in pure oxygen, apparently because oxidation takes place so rapidly that the animal is incapable of assimilating sufficient food to supply the waste; but by admixture with the perfectly neutral nitrogen the activity of the oxygen becomes greatly diminished.

Air from open places contains usually from 3 to 6 volumes of carbon dioxide in 10,000 volumes, but the amount of carbon dioxide in the atmosphere is subject to continual change, although within narrow limits. It does not continually increase in amount, notwithstanding that animals expire carbon dioxide, and that large quantities are produced by the combustion of wood and coal, because plants exercise a power which is the reverse of that of which animals are possessed, viz., that of decomposing carbon dioxide and restoring its oxygen to the atmosphere.

Ammonia, NH_3 ; Mol. wt., 17.

Ammonia is the only compound of nitrogen and hydrogen which is known to us. It may be formed directly

from its elements by submitting a mixture of the two gases to the action of the silent electric discharge; the combination is very imperfect, however. It is also obtained by the action of nascent hydrogen on nitric acid and many of its salts; but it is always prepared by heating an ammonium salt with an alkaline hydroxide, ammonium chloride and calcium hydroxide or slaked lime being the substances which are usually employed—

Ammonia is a product of the decay of all nitrogenous animal and vegetable substances, and the ammonia present in the atmosphere is chiefly if not entirely derived from this source; but it appears not improbable that ammonia is directly produced in the atmosphere by the decomposition of water into its elements by the electric discharge, and the combination also under the influence of the discharge of the hydrogen thus produced with nitrogen. Ammonia is present in the atmosphere apparently as carbonate, and in rain-water, especially in that of thunder showers, as nitrate and nitrite. Ammonia salts are sometimes found as minerals, chiefly in volcanic districts. The source from which ammonia salts are now obtained, however, is the watery liquid which distils over in the manufacture of coal gas; the ammonia is liberated from this liquid by heating it with slaked lime, and by receiving it in sulphuric acid ammonium sulphate is produced,—a salt which is largely employed as an artificial manure.

Ammonia is a transparent colourless gas, of a very pungent peculiar odour, and a burning taste. It may be reduced to the liquid state by a pressure of about 17 atmospheres at the ordinary temperature, or by cold alone at about -50° to -40° C.; by exposing the dry gas to a cold of -75° C. and a pressure of 20 atmospheres, Faraday obtained ammonia as a white transparent crystalline body, melting at -75° C. It does not support combustion, and is only feebly combustible. It is decomposed into its elements by a succession of electric sparks.

Ammonia is dissolved by water with great avidity, much heat being developed and great expansion taking place; according to Roscoe and Dittmar, 1 gramme of water at 0° C. dissolves no less than 875 grammes of ammonia. The solution has the smell and taste of the gas, and a powerfully alkaline reaction; it loses almost all its ammonia below 100° C.

Ammonia completely neutralizes acids, forming definite crystalline salts, known as ammonium salts, which are formed by the direct combination of ammonia with the acids; ammonia and hydrochloric acid, for example, form ammonium chloride, $\text{NH}_4\text{Cl} = \text{NH}_3 + \text{HCl}$, whilst ammonia and sulphuric acid furnish ammonium sulphate, $(\text{NH}_4)_2\text{SO}_4 = 2\text{NH}_3 + \text{H}_2\text{SO}_4$. The constitution of these salts, it will be evident, is analogous to that of the salts of the metals generally if we regard them as derived from the acids by the displacement of the hydrogen of the latter by the monad compound radicle *ammonium*, NH_4 , and this view is confirmed by the observation that the ammonium salts are isomorphous with the corresponding potassium salts. They are all soluble in water, and are readily decomposed by the alkaline hydroxides, and by most basic oxides, with evolution of ammonia.

The solution of ammonia in water is frequently regarded as the hydroxide of the hypothetical radicle ammonium, that is to say, as a solution of ammonium hydroxide, NH_4OH , the analogue of potassium hydroxide, KOH . But Thomsen has shown that considerably less heat is developed when an acid is neutralized by a solution of ammonia than when it is neutralized by a solution of an alkaline hydroxide, such as potassium hydroxide, for

example, the reaction KHOAq , HClAq being accompanied by the development of 27,500 units of heat, whilst only 24,500 are developed in the reaction NH_3Aq , HClAq . Thomsen is inclined to regard this result as evidence that ammonia exists as such in its aqueous solution, and not as the hydroxide NH_4OH , but the difference observed appears scarcely sufficient to warrant this conclusion in the face of the chemical evidence which points to the existence of an ammonium hydroxide; it is more probable, perhaps, that an aqueous solution of ammonia consists in part of the hydroxide and in part of free ammonia.

A very large number of derivatives may be obtained from ammonia by displacing one or more atoms of hydrogen in it by positive or negative radicles. Those which are formed by the introduction of monad positive radicles are distinguished by the name *amines*, whilst those containing monad negative radicles are called *amides*; when two atoms of hydrogen in a single molecule of ammonia are displaced by dyad negative radicles so-called *imides* are produced. A simple instance of the formation of an amine derivative is afforded by the action which takes place when potassium is heated in an atmosphere of ammonia—

By digesting iodine in an excess of aqueous ammonia a black explosive compound is produced, which apparently is formed by the displacement of two of the atoms of hydrogen by iodine—

It may be exploded by friction even under water, and in the dry state can scarcely be touched without exploding. When chlorine is passed into an aqueous solution of ammonia, nitrogen is evolved and ammonium chloride is produced; thus—

If the action of the chlorine be continued after the whole of the ammonia is thus acted upon, the ammonium chloride becomes attacked, and yellow oily drops of the so-called chloride of nitrogen are formed. The composition of this substance has not yet been satisfactorily ascertained; it probably contains hydrogen, and its formula is supposed to be NHCl_2 , but it is not unlikely that the compound NCl_3 is also produced. It explodes with extreme violence when heated, or when brought in contact with fatty matters, or with turpentine, phosphorus, and many other substances.

The Oxides and Acids of Nitrogen.

No less than five oxides of nitrogen are known, viz.—

Nitrous and nitric oxide are merely dissolved by water but the remaining oxides enter into reaction with it producing acids,—nitrous and nitric anhydride being converted into the corresponding acids, nitrous and nitric acid, and a mixture of those two acids being formed from the intermediate oxide, nitric peroxide; thus—

As these various oxides of nitrogen are all prepared from nitric acid, we may conveniently describe this compound as the first of the series.

Nitric Acid, HNO₃.

This acid is now usually prepared by distilling sodium nitrate or Chili saltpetre, a salt which occurs abundantly in South America, with concentrated sulphuric acid in the proportions indicated by the equation—

When potassic nitrate is employed, it is advantageous to use double the quantity of sulphuric acid; thus—

as the heat required to produce the reaction—

is so great that a considerable amount of the acid is decomposed.

The acid passes over as an almost colourless liquid in the middle of the process, but is coloured at the beginning and end by decomposition products. To obtain the pure acid, it is mixed with an equal bulk of concentrated sulphuric acid, and the mixture distilled; the first portions of the distillate are collected, and a current of dry air passed for several hours through the liquid, which is gently warmed and sheltered from strong daylight.

Pure nitric acid is a colourless, mobile, fuming liquid, of the specific gravity 1.53 at 15° C.; it solidifies at about 55° C. It is an extremely unstable substance, and cannot be distilled without experiencing partial decomposition; it is also decomposed when exposed to sunlight, becoming yellow, and oxygen being evolved. It begins to boil at 86° C., but the temperature rises gradually, and oxygen and red fumes of oxides of nitrogen are evolved; when the boiling point reaches about 123° C., an aqueous acid, having a specific gravity of about 1.42, and containing about 68 per cent. of nitric acid, distils unchanged, and weaker and stronger acids may alike be reduced to this strength by boiling. As in the case of other aqueous acids, however, the composition of nitric acid of constant boiling point varies with the pressure under which ebullition takes place.

The addition of water to nitric acid causes the development of heat. The following table shows the extent to which this occurs, the amount of heat developed on adding *n* molecules of water to a molecule of the acid being given in the second column of the table, whilst the third exhibits the amount developed on adding a quantity of water equal to that already present:—

<i>n</i> .	$\text{NHNO}_3, n\text{H}_2\text{O}.$	$\text{HNO}_3, n\text{H}_2\text{O}, n\text{H}_2\text{O}.$
0.5	2019 units.	1284 units.
1.0	3303 "	" "
1.5	4185 "	1572 "
2.0	4814 "	" "
2.5	5331 "	1388 "
3	5757 "	" "
4	6316 "	" "
5	6719 "	653 "
10	7372 "	139 "
20	7511 "	-14 "
40	7497 "	-15 "
80	7482 "	+29 "
100	7477 "	" "
160	7511 "	+74 "
320	7585 "	" "

These numbers do not appear to furnish any evidence of the formation of a distinct hydrate on adding water to nitric acid.

Nitric acid is a monobasic acid, and furnishes an important class of salts called *nitrates*, such as potassium nitrate, KNO_3 , copper nitrate, $\text{Cu}(\text{NO}_3)_2$, and bismuth nitrate, $\text{Bi}(\text{NO}_3)_3$. In addition to these normal nitrates, a number of so-called basic nitrates are known which may be regarded

as normal salts of a distinct acid, formed by the combination of a molecule of nitric acid with a molecule of water; such are the basic bismuth nitrate BiNO_4 and the basic lead nitrates $\text{Pb}_2\text{H}_2\text{N}_2\text{O}_8$ and $\text{Pb}_3\text{N}_2\text{O}_8$. The normal nitrates are best prepared by dissolving the metallic oxides, hydroxides, or carbonates in diluted nitric acid; they are all soluble in water. The most important nitrate is that of potassium, which is employed in the manufacture of gunpowder.

Nitric acid is an extremely powerful oxidizing agent, and one of the most corrosive substances known; it rapidly destroys all animal textures and most vegetable products, and even if diluted it stains the skin, wool, and all albuminous substances a bright yellow colour. Many hydrogenized carbon compounds are converted by it into so-called nitro-derivatives, one or more atoms of hydrogen being displaced by the monad compound radicle NO_2 ; the hydrocarbon benzene, for example, when added to the concentrated acid yields nitrobenzene—

Most metals, excepting gold, platinum, rhodium, iridium, titanium, and perhaps a few others, are more or less readily acted on by nitric acid and converted into nitrates; but the non-metallic elements and metalloids—iodine, sulphur, selenium, tellurium, phosphorus, arsenic, antimony, amorphous boron and carbon, and tungsten—are oxidized by it, and furnish iodic, sulphuric, selenious, tellurous, phosphoric, arsenic, antimonie, boric, carbonic, and tungstic acids.

The action of nitric acid on metals, however, is much influenced by temperature and concentration. An acid of the specific gravity 1.25 to 1.35 is usually the most active. The pure concentrated acid is without action on bismuth, iron, tin, and many other metals at ordinary temperatures. Thus, a piece of bright iron is at once attacked by an acid of about the specific gravity 1.35, but it may be preserved in acid of the specific gravity 1.45 without losing its brilliancy; what is more remarkable, however, is that by plunging it into the more concentrated acid it is rendered *passive* to the action of the weaker acid, for on removing it and at once introducing it into the weaker acid, no action is observed, although on diluting the acid below 1.35 the iron is attacked.

In order, however, to understand the behaviour of nitric acid with metals, it is necessary that we should first consider the action of metals upon acids generally. There is little doubt that in all cases the metal simply displaces the hydrogen of the acid, forming a salt; and if, under the conditions under which the experiment is made, the acid has no tendency to enter into reaction with the hydrogen which is displaced, whilst it is in the nascent state, hydrogen is also evolved; but if the acid can enter into reaction with the nascent hydrogen the products of this secondary reaction are obtained instead. For example, zinc readily dissolves in cold diluted sulphuric acid, forming zinc sulphate, and hydrogen is evolved since it is without action on sulphuric acid under these conditions—

But when zinc and concentrated sulphuric acid are heated together, zinc sulphate and sulphur dioxide are obtained, and no hydrogen is evolved. In this case, the hydrogen is displaced from the sulphuric acid under conditions which are favourable to its action upon the acid, and it deprives the acid of a portion of its oxygen, forming sulphurous acid, which is at once resolved into water and sulphur dioxide.

The behaviour of nitric acid with metals is precisely similar to that of zinc with heated concentrated sulphuric acid, nitric acid being a substance which with the greatest

readiness may be deprived of its oxygen by the action of nascent hydrogen. In fact, hydrogen is never evolved by the action of metals on nitric acid, but instead oxides of nitrogen, nitrogen itself, ammonia, and other products of secondary reaction are obtained. The formation of these products is due to a somewhat complex series of reactions, which most probably are as follows. In the first place, by the removal of one of the atoms of oxygen the nitric acid is converted into nitrous acid, HNO_2 ; by further reduction this acid furnishes the so-called hyponitrous acid, HNO ; and by the continued action of the nascent hydrogen the hyponitrous acid is converted into hydroxylamine or oxyammonia, $\text{NH}_2(\text{OH})$, which finally is reduced to ammonia, NH_3 . The reactions which successively occur in the formation of these compounds are represented by the following equations:—

But the products of these reactions enter into reaction with each other, and are decomposed, and thus the gases are produced which are evolved when metals are dissolved in nitric acid. The nitric oxide doubtless results chiefly from the decomposition of the nitrous acid in the manner represented by the equation—

The nitrous oxide may be produced in two ways:—from hyponitrous acid, which immediately on formation is resolved into nitrous oxide and water: $2\text{HNO} = \text{N}_2\text{O} + \text{H}_2\text{O}$; and by the action of nitrous acid on hydroxylamine—

The nitrogen produced is probably formed in a similar manner by the action of the nitrous acid on the ammonia—

and perhaps also, together with nitric oxide, by the action of nitric acid on hyponitrous acid.

As the product of the action of nitric acid on a metal is always a mixture, it is evident that several of the reactions pointed out must occur simultaneously. The composition of the product varies, in a manner not yet understood, with the metal, the strength of the acid, and with the temperature.

The approximate percentage composition of the gas obtained by the action of a mixture of nitric acid of the specific gravity 1.42 with twice its bulk of water on a number of metals is given in the following table:—

Name of Metal.	N_2O	NO	N
Nickel	85	4	11
Cobalt.....	79	6	15
Tin	68	23	9
Magnesium	61	17	22
Zinc	53	40	7
Lead	41	52	7
Cadmium	20	78	2
Thallium	19	70	11
Iron ..	6	89	5
Indium.....	4	91	5
Aluminium	1	97	2
Copper.....	1.5	97	1.5
Silver.....	0	97	3

It is difficult at present to explain the remarkable difference in the behaviour of the various metals with nitric

acid which this table indicates. As we have stated above, the action of the metal probably consists simply in displacing the hydrogen of the acid, and the gases evolved are the more or less direct products of the action of the hydrogen so displaced at the moment of liberation on the acid which is always present in excess. The question, therefore, that we have to consider is, Why does the hydrogen displaced from nitric acid by different metals produce such very different effects? If the behaviour of closely related metals such as magnesium, zinc, and cadmium be compared, it is evident that magnesium is the most active, since it produces a relatively smaller quantity of nitric oxide, and relatively larger quantities of nitrous oxide and nitrogen, than either zinc or cadmium, cadmium being the least active; in other words, the reduction of the nitric acid is most perfect when it is effected by the hydrogen displaced by the aid of magnesium, and least perfect when it is effected by the aid of cadmium. We know that when these metals act upon acids which are not attacked by nascent hydrogen, such as hydrochloric acid, for example, different amounts of heat are developed, most heat being developed by the action of magnesium, and least by the action of cadmium. But since the mere displacement of hydrogen in hydrochloric acid by different metals is attended with the development of different amounts of heat, it appears probable that the same will be the case with nitric acid, and also that more heat would be developed in the reaction

than in the corresponding reactions with either zinc or cadmium; and that on this account the reduction of nitric acid is carried furthest when magnesium is employed, and further with zinc than with cadmium. Whether this explanation is applicable to the action of metals generally there is not sufficient evidence at present to show.

Nitrous Oxide, N_2O ; Mol. wt., 44.06.

This gas is obtained in a pure state by carefully heating ammonium nitrate, which at a temperature between 200° and 250°C . breaks up into water and nitrous oxide—

It is the chief constituent of the gas produced on dissolving magnesium, zinc, tin, nickel, or cobalt in nitric acid, and it is also furnished, but to a less extent, by other metals.

Nitrous oxide is a transparent colourless gas, possessing a faint sweetish smell and taste; it may be condensed by a pressure of about 50 atmospheres at 7°C . to a colourless liquid, and even frozen by the cold produced by its own evaporation. By exposing a mixture of liquid nitrous oxide and carbon disulphide to evaporation in vacuo, Natterer obtained a reduction of temperature which he estimated at -140°C ., which is lower than has been obtained by any other means. 100 volumes of water at 0°C . dissolve 130 of nitrous oxide, but the solubility diminishes rapidly as the temperature rises. It supports the combustion of bodies almost, if not quite, as well as oxygen, but is readily distinguished from that gas by its solubility in water, and by not forming red fumes when mixed with nitric oxide gas.

The most remarkable property which nitrous oxide gas possesses is that of causing loss of sensibility in animals. When respired for a short time it produces a singular species of transient intoxication, attended in many instances with an irresistible tendency to muscular exertion, and often to uncontrollable laughter; hence it has acquired the name of *laughing gas*. It is now largely used as an anæsthetic for producing insensibility to pain during surgical operations, and especially in the extraction of teeth.

Nitrous oxide is a perfectly neutral substance, and does

not exhibit any tendency to enter into combination with other bodies.

Nitric Oxide, NO; Mol. wt., 29.96.

This gas is one of the products of the action of nitric acid on metals; the gas obtained on dissolving copper in moderately concentrated nitric acid contains at first about 97 per cent. of nitric oxide, but as the action proceeds and cupric nitrate accumulates in the solution, the proportion of nitric oxide evolved diminishes, whilst that of nitrous oxide increases. This appears to be due to the alternate reduction of the cupric nitrate to cuprous nitrate—

and reconversion of the latter into cupric nitrate, as by the action of nitric acid on cuprous nitrate nitric oxide mixed with a large proportion of nitrous oxide is produced.

Pure nitric oxide may be prepared by gently heating a mixture of a ferrous salt, such as ferrous chloride or ferrous sulphate, with hydrochloric or dilute sulphuric acid and potassium or sodium nitrate. The nitric acid liberated from the nitrate is reduced by the ferrous salt, which is oxidized to a ferric salt, and nitric oxide is evolved—

Nitric oxide is a colourless, transparent, uncondensable gas, almost insoluble in water; it is the most stable of the oxides of nitrogen, and may even be exposed to a red heat without undergoing decomposition. A lighted taper and phosphorus just kindled are extinguished by it, but if the phosphorus be burning vigorously when introduced into the gas the temperature is then sufficiently high to enable it to decompose the gas into its elements, and it continues to burn as brilliantly as in pure oxygen.

Nitric oxide immediately combines with oxygen when mixed with it, forming deep red fumes of higher oxides of nitrogen. It is perfectly absorbed by a solution of ferrous chloride or sulphate, which it turns black; when the solution is heated, most of the nitric oxide is expelled from it unchanged, and in this way nitric oxide may be separated from other gases insoluble in solutions of the ferrous salts. Nitric oxide is absorbed by nitric acid, and apparently nitrous acid is produced—

It combines directly with chlorine, forming the compound NOCl, or nitrosyl chloride, which is also produced together with chlorine when a mixture of concentrated nitric and hydrochloric acids—the so-called aqua regia—is heated—

Nitrosyl chloride is most readily prepared, however, by gently heating a mixture of dry sodium chloride and the lead chamber crystal compound (p. 504)—

It is an orange-yellow coloured gas, which readily liquefies; the liquid has a deep orange colour, and boils at about -8°C . It is decomposed by water, forming hydrochloric and nitrous acids—

Nitrous Anhydride, N_2O_3 .

The properties of this compound have not yet been satisfactorily ascertained. Apparently, it is produced, together with nitric peroxide, when nitric oxide is mixed with oxygen, and when nitric acid is heated with arsenious anhydride; it is stated that it may be prepared in a pure

state by passing a mixture of nitric peroxide with an excess of nitric oxide through a heated tube, and that it may be condensed to a deep blue coloured liquid, which begins to boil at about 2°C ., but is decomposed into nitric oxide and peroxide. It combines readily at ordinary temperatures with oxygen, forming nitric peroxide.

Nitric Peroxide, N_2O_4 ; Mol. wt., 91.86.

Nitric peroxide may be obtained by combining nitric oxide with oxygen, and by heating lead nitrate—

At low temperatures it forms colourless prismatic crystals, which melt at -9°C .; at this temperature the liquid oxide is almost colourless, but it assumes a yellow colour, increasing in depth up to its boiling point. It boils at about 25°C ., yielding a brownish-red vapour, the depth of which also increases with the temperature, until at 40°C . it is so dark as to be almost opaque. The vapour of nitric peroxide, however, probably even at temperatures below its boiling point, is a mixture of the compound N_2O_4 with simpler molecules of the composition NO_2 ; the proportion of the latter increases as the temperature rises, and at temperatures above 150°C . the decomposition into NO_2 is apparently complete. The compound NO_2 is not decomposed at a dull red heat.

Nitric peroxide has a pungent suffocating odour, and is quite irrespirable. It is decomposed by water with production of nitrous and nitric acids: $\text{N}_2\text{O}_4 + \text{H}_2\text{O} = \text{HNO}_2 + \text{HNO}_3$. Chlorine is without action on nitric peroxide in the cold, but when a mixture of the two gases is passed through a heated tube the compound NO_2Cl or nitrylic chloride is formed. It is a pale yellow liquid, which is decomposed by water into nitric and hydrochloric acids.

Nitric Anhydride, N_2O_5 .

This compound may be obtained directly from nitric acid by the action of phosphoric anhydride—

It may also be obtained by the action of chlorine on silver nitrate—

Nitric anhydride crystallizes in transparent prisms, which melt at about 30°C .; it is very unstable, particularly in the fused state, and gradually decomposes even at ordinary temperatures into oxygen and nitric peroxide. Water converts it into nitric acid: $\text{N}_2\text{O}_5 + \text{H}_2\text{O} = 2\text{HNO}_3$.

Nitrous Acid, HNO_2 .

In the pure state this compound is unknown to us, but its salts, the *nitrites*, may readily be prepared. Thus, on heating sodium or potassium nitrate to redness until the gas which is evolved begins to contain nitrogen, a residue which consists chiefly of sodium or potassium nitrite is obtained; these nitrites are soluble in alcohol, and may by its aid be separated from the nitrates, which are insoluble. A mixture of nitrate and nitrite is also produced on passing the gas evolved when nitric acid is heated with arsenious anhydride, starch, or sugar into a solution of potassium or sodium hydroxide, and when oxygen is added to nitric oxide which is in contact with a solution of an alkali. On adding silver nitrate solution to a concentrated solution of the impure nitrite, silver nitrite, AgNO_2 , which is difficultly soluble in water, is precipitated; this salt may be purified by crystallization

from a large quantity of hot water, and from it other nitrites may be prepared in a pure state by double decomposition with the corresponding chlorides; thus—

Although oxygen and nitrogen do not directly combine, when a succession of electric sparks is passed through a mixture of the two gases confined over water, red fumes are produced which dissolve in the water, forming nitric and nitrous acids. The nitrite and nitrate present in the atmosphere and in rain-water are doubtless formed in this manner.

On adding an acid to a nitrite, nitrous acid is liberated, but at once decomposes with evolution of nitric oxide—

Nitrous acid can only exist, in fact, in presence of a large quantity of water, or of nitric acid. It parts with its oxygen more readily, and is therefore a more powerful oxidizing agent, than nitric acid. It also appears to act more readily than nitric acid upon many metals. Thus, pure nitric acid is almost without action upon silver, but on passing a few bubbles of nitric oxide gas into the acid, and thus producing a minute quantity of nitrous acid, the metal is at once attacked, and is dissolved more and more rapidly the longer the action continues, doubtless because the hydrogen displaced from the acid by the silver reduces nitric acid to nitrous acid, so that the more silver is dissolved the richer the solution becomes in nitrous acid. Platinum also, which is insoluble in nitric acid, is dissolved by nitrous acid.

On some hydrogenized carbon compounds nitrous acid exerts an action similar to that of nitric acid, and causes the displacement of hydrogen by the monad compound radicle NO, producing *nitroso*-compounds. Thus—

Nitrous acid readily absorbs oxygen, and is converted into nitric acid. The nitrites are also converted into nitrates when exposed in the moist state to air. Nitrous acid is easily distinguished from nitric acid by its power of liberating iodine from iodides, by the readiness with which it destroys the blue colour of a solution of indigo at ordinary temperatures, and by its decolorizing a solution of potassium permanganate,—nitric acid being without the power of liberating iodine from iodides, or of bleaching permanganate solution.

Hyponitrous Acid, HNO.

When sodium is added to a solution of sodium nitrate, the hydrogen displaced from the water by the sodium reduces the nitrate to nitrite, which in its turn undergoes further reduction to the hyponitrite, NaNO . On rendering the solution slightly acid with acetic acid, and adding silver nitrate, a yellow pulverulent precipitate of silver hyponitrite, AgNO , is produced. It is insoluble in water, and almost insoluble in acetic acid, but is soluble in either dilute nitric or sulphuric acid, and without immediate decomposition. Moderately diluted nitric, sulphuric, or hydrochloric acid decomposes it with the evolution of nitrogen, and the production of apparently both nitrous and nitric acids in the solution. It is immediately oxidized by concentrated nitric acid. A solution of the sodium salt acidified with acetic or hydrochloric acid decolorizes potassium permanganate; it does not liberate iodine from iodides, however, but on the contrary decolorizes a solution of iodine. When the solution acidified with acetic acid is heated, nitrous oxide is evolved.

Hydroxylamine, $\text{NH}_2(\text{OH})$.

This compound is formed when nitric acid is added to a mixture of tin and hydrochloric acid, the hydrogen produced by the action of the tin on the hydrochloric acid reducing the nitric acid. It may also be formed by the direct union of nitric oxide with hydrogen, namely, by passing a stream of nitric oxide gas through a series of glass cylinders containing tin and hydrochloric acid, together with a little platinum chloride solution, whereby hydrogen is produced at ordinary temperatures.

It is a very unstable substance, and can be obtained only in solution, but well-crystallized *hydroxylammonium* salts are formed by its union with acids. Thus, the hydrochloride, $\text{NH}_2\text{Cl}(\text{OH})$, or $\text{NH}_2(\text{OH})\cdot\text{HCl}$, crystallizes from alcohol in long spicular crystals, and from water in large irregular monoclinic prisms; it melts at 100°C ., but decomposes, with violent evolution of gas, into nitrogen, ammonium chloride, water, and hydrochloric acid. A solution of hydroxylamine has an alkaline reaction, and precipitates many metallic salts; it decomposes quickly if concentrated, and gradually if dilute, with evolution of nitrogen and formation of ammonia—

Hydroxylamine is readily reduced to ammonia by the action of the nascent hydrogen from sodium amalgam and water.

The results of Thomsen's thermochemical investigation of various nitrogen compounds are collected in the following table :—

Reaction.	Units of heat developed or absorbed.	Remarks.
Ammonia { (N, H_3)	26,710	Ammonia gas.

It will be observed that a considerable amount of heat would be absorbed in the formation of nitrous oxide from its elements; consequently, when this gas is decomposed into its elements, heat is developed, and on this account it is readily decomposed by burning bodies. This fact also explains the non-formation of nitrous oxide from its elements. Probably, heat would also be absorbed in the formation of nitric oxide from its elements. The absorption of heat is perhaps necessary, because the amount of energy in the form of heat which can be developed by the combination of nitrogen with oxygen to form nitrous and (?) nitric oxides is less than must be expended in separating the atoms of oxygen of the oxygen molecules from each other, and the atoms of nitrogen of the nitrogen molecules from each other.

PHOSPHORUS.

Symbol, P; At. wt., 30.96; Mol. wt. of gas, 123.84.

This element never occurs in the free state, but is always found in combination as a salt of phosphoric acid. Considerable deposits of more or less pure calcium phosphate occur in a few places, and phosphates are found in minute proportions in most rocks and in soils, and in river and spring waters. Phosphates are necessary to the life of all plants and animals. In plants they accumulate chiefly in the seed; in animals they accumulate in the bones, of which calcium phosphate is the chief earthy constituent, but they are also an important element of blood and nervous tissue.

Phosphorus was discovered in 1669 by Brandt of Hamburg, who obtained it by distilling the residue of evaporated urine with charcoal. Scheele in 1775, however, was the first who devised a process for its extraction from bones, and it has always since been prepared from this source. The bones are burnt to a white ash, which is finely powdered and mixed with a sufficient quantity of diluted sulphuric acid to displace by hydrogen two-thirds of the calcium in the tricalcium phosphate, which is the main constituent of bone ash, in the manner represented by the equation—

The solution of monocalcium phosphate, or superphosphate of lime as it is ordinarily termed, which is obtained, is separated from the insoluble calcium sulphate, and evaporated to a syrup; this is mixed with about one-fourth its weight of charcoal powder, and heated gradually to dull redness in an iron pot with constant stirring. By this means the elements of two molecules of water are removed, the monocalcium phosphate being converted into calcium metaphosphate—

The porous mixture of calcium metaphosphate and charcoal thus obtained is introduced into earthen retorts, and distilled at a bright red heat. The calcium metaphosphate is then converted into tricalcium phosphate and phosphoric anhydride, and the latter is decomposed by the charcoal into carbonic oxide and phosphorus, which passes over in vapour and is condensed in water—

The crude phosphorus which is produced is usually purified by adding a mixture of potassium chromate and sulphuric acid to it when in a melted state. The impurities are thus oxidized, and rise to the surface in the form of a scum, and the pure phosphorus remains colourless and transparent at the bottom of the vessel.

Freshly-prepared phosphorus is almost perfectly transparent and colourless, or has, at most, a faint yellow tinge. It melts at 44° C., forming a viscid oily liquid, and boils at 290° C. Its vapour at a temperature of 1040° C. is about 62 times as heavy as hydrogen gas, and hence, as the atomic weight of phosphorus is about 31, it appears that the molecule of gaseous phosphorus is tetra-atomic. Phosphorus has a specific gravity of about 1.82. It is a non-conductor of heat and electricity. It is insoluble in water, but freely soluble in carbon disulphide, phosphorus trichloride, and sulphur chloride, S_2Cl_2 . It crystallizes in forms of the regular system.

Phosphorus is extremely inflammable, taking fire in the open air at a temperature very little above its melting point; if it contains impurities, it inflames still more easily. It gradually absorbs oxygen when exposed to the

air at ordinary temperatures, giving off a white vapour, which has a peculiar garlic odour; in presence of moisture phosphorous acid, H_3PO_3 , and phosphoric acid, H_3PO_4 , are produced.

Phosphorus, like sulphur, can exist in several allotropic modifications, the most remarkable being that produced by exposing ordinary phosphorus to light, or by heating it for some hours to a temperature of about 240° C. in an atmosphere free from oxygen. It is thus converted into a red amorphous substance, which is insoluble in carbon disulphide, and may be heated to 250° C. without alteration, but at 260° C., under the ordinary pressure, it is reconverted into ordinary phosphorus. The red modification has a much higher specific gravity (2.14) than ordinary phosphorus, and it is also distinguished by its inertness as compared with the latter; thus, it is not oxidized in the air at common temperatures, and it emits no odour. The transformation of ordinary phosphorus into this variety is attended with development of heat. Troost and Hautefeuille have shown that the formation of the red modification is governed by different laws according as the phosphorus is in the state of gas or liquid, and that it takes place much more rapidly in the latter case. When the tension of the vapour becomes diminished to a certain minimum value, varying for each temperature, the transformation ceases; this tension of transformation is established only after some time. Liquid phosphorus at 280° C., for instance, becomes wholly transformed into red phosphorus. The vapour given off at 260° C. is stable, but that formed at higher temperatures becomes slowly and partially converted into red phosphorus, the production of which ceases when the tension attains a given minimum; the rapidity with which this change takes place is greater the higher the temperature. At temperatures up to 520° C., however, the maximum tensions of phosphorus vapour are much higher than the tensions of transformation; thus, at 360° C. the tension of transformation is .6 atmosphere, but to prevent phosphorus boiling at this temperature, a pressure of 3.2 atmospheres must be exerted. Above 520° C. the maximum tension is not established on account of the rapidity with which the transformation takes place; and at temperatures above 550° C. the tension observed is no greater than the tension of transformation, because the transformation of the liquid phosphorus takes place more rapidly than its evaporation. The observed maximum tension and tension of transformation at different temperatures are given in the following table:—

Temperature.	Maximum tension.	Tension of transformation.
360°	3.2 atmospheres	0.6 atmospheres
440°	7.5 "	1.75 "
487°	..	6.8 "
494°	18.0 "	..
503°	21.9 "	..
510°	..	10.8 "
511°	26.2 "	..
531°	..	16.0 "
550°	..	31.0 "
577°	..	56.0 "

The red phosphorus produced by heating ordinary phosphorus in closed vessels differs, however, in appearance according to the temperature at which it is prepared. That obtained at 265° C. has a bright red colour and glassy fracture; that produced at 440° C. is orange-yellow in colour, and exhibits a dull fracture; at 500° C. it is denser, and has a violet grey colour; and, lastly, that prepared at 580° C. has a conchoidal fracture, exhibits signs of commencing fusion, and often encloses ruby red crystals. These modifications differ also in specific gravity, and when oxidized to phosphoric acid by iodic acid solution they develop different amounts of heat. Thus—

Temperature of formation.	Sp. gr. at 0° C.	Heat of oxidation per gramme.
265°	2.148	5592 units.
360°	2.19	5570 "
500°	2.293	above 5272 "
580° (fused)	?	5222 "
580° (crystalline)	2.34	5272 "

Hydrogen, except in the nascent state, appears to be without action on phosphorus. Oxygen forms the two oxides P_2O_3 and P_2O_5 . Chlorine, bromine, and iodine enter directly into reaction with ordinary phosphorus, the combination being attended with inflammation; red phosphorus also enters into reaction with these elements at ordinary temperatures, and heat is developed, although to a much less extent. When sulphur and ordinary phosphorus are melted together, combination takes place with great violence, and the experiment of bringing the two bodies together is attended with much danger. If dissolved in carbon disulphide, they are without action upon each other. Red phosphorus readily enters into reaction with sulphur when a mixture of the two substances is gently warmed, and although much heat is developed by their combination, the reaction is not explosively violent. Selenium also unites with phosphorus when the two are heated together nearly to the boiling point of the latter. Most metals combine with phosphorus when they are heated in its vapour, or when it is thrown upon them whilst they are in a state of ignition.

Compounds of Phosphorus with Hydrogen.

Three of these compounds are known, viz., phosphine or phosphoretted hydrogen gas, PH_3 , and a liquid and a solid hydrogen phosphide.

Phosphine is obtained in a pure state by decomposing phosphonium iodide by a solution of potassium or sodium hydroxide: $PH_4I + KHO = PH_3 + KI + H_2O$. It is a colourless gas, possessing a most intolerable garlic-like odour; it is sparingly soluble in water, the solution being neutral to test paper. Phosphine is extremely inflammable, igniting at a temperature a little above 100° C.; contact with a drop of fuming nitric acid, or with chlorine or bromine, also causes it to inflame. A mixture of the gas with oxygen standing over water is gradually absorbed, and phosphorous acid produced. It is a powerful reducing agent, withdrawing oxygen with great readiness from bodies like nitric oxide, sulphur dioxide, and sulphuric acid. It precipitates many metallic salts, the precipitate in most cases consisting either of metallic phosphide, as in the case of copper, or of reduced metal, as in the case of gold and silver. It combines with hydriodic acid, forming phosphonium iodide, PH_4I , and with hydrobromic acid forming phosphonium bromide, PH_4Br , but not with hydrochloric acid or other acids; these salts are crystalline bodies, which are decomposed by water into phosphine and hydriodic or hydrobromic acid.

Phosphine mixed with more or less hydrogen is obtained by the action of water on the calcium phosphide, prepared by heating phosphorus with lime; by heating phosphorus with a solution of an alkaline hydroxide—

and when phosphorous, or hypophosphorous, acid is heated—

The gas obtained by the first and second methods is spontaneously inflammable, owing to the presence of liquid hydrogen phosphide, which may be separated by passing the gas through a U-tube cooled by a mixture of ice and

salt. Liquid hydrogen phosphide probably has the composition P_2H_4 ; by contact with various substances, and especially by hydrochloric acid, and by exposure to light, it is converted into phosphine and a yellowish solid hydrogen phosphide, supposed to have the composition P_2H or P_4H_2 —

Compounds of Phosphorus with the Halogens.

A gaseous phosphorus pentafluoride may be obtained by the action of phosphorus pentachloride on arsenic trifluoride: $5AsF_3 + 3PCl_5 = 3PF_5 + 5AsCl_3$. It is not decomposed by the passage of electric sparks, even when mixed with oxygen or hydrogen. Two chlorides of phosphorus are produced by the action of chlorine on phosphorus,—a liquid trichloride, PCl_3 , and a solid pentachloride, PCl_5 . Bromine in like manner forms a liquid tribromide, PBr_3 , and a solid pentabromide, PBr_5 . Bromine also combines with phosphorus trichloride, forming the chlorobromide PCl_2Br_2 , and this compound is capable of combining with further quantities of bromine, forming the compounds PCl_2Br_3 , Br_2 and PCl_2Br_4 , $3Br_2$; all these chlorobromides of phosphorus are crystalline bodies. Iodine forms the two iodides PI_3 and P_2I_4 , which are both crystalline.

Phosphorus trichloride boils at 76° C., and the tribromide is also volatile without decomposition, but the remaining chlorine and bromine compounds of phosphorus are decomposed by heat into the trihaloid compounds and halogen: $PCl_5 = PCl_3 + Cl_2$. The iodides are also decomposed by heat, apparently into iodine and amorphous phosphorus.

The haloid compounds of phosphorus are all readily decomposed by water. The pentachloride and pentabromide are first converted into the oxychloride and oxybromide, two of the atoms of halogen being displaced by a single atom of oxygen—

and by the continued action of water these compounds are converted into phosphoric acid; thus—

The behaviour of the trihaloid compounds of phosphorus is analogous to that of the oxychloride and oxybromide, phosphorous acid being produced—

The compounds containing more than five atoms of halogen behave as mixtures of the pentahaloid compounds with halogens—that is to say, they furnish the products of the decomposition by water of the pentahaloid compound, and also the free halogen. The iodide of phosphorus, P_2I_4 , is peculiar in its behaviour with water; it is stated that when it is decomposed by a small quantity of water only phosphorous and hypophosphorous acids are formed—

but that when a large quantity of water is employed, a yellow insoluble substance of the composition P_5H_3O is produced, the reaction taking place in the manner represented by the equation—

Oxides of Phosphorus.

The combustion of phosphorus in air produces both phosphorous and phosphoric anhydrides, P_2O_3 and P_2O_5 ; the latter may be readily obtained by burning phosphorus

in an excess of dry air, but it is almost impossible to obtain the former free from the latter. The best mode of preparing the trioxide is to burn phosphorus in a very slow current of dry air; it then condenses as a bulky white amorphous sublimate.

Phosphorous anhydride is readily soluble; it absorbs moisture with avidity, and dissolves in water, producing phosphorous acid: $P_2O_3 + 3H_2O = 2H_3PO_3$.

Phosphoric anhydride is a snow-white, flocculent, amorphous substance. It sublimes below a red heat. It has an attraction for water which probably is only exceeded by that of sulphuric anhydride, deliquescing quickly in moist air, and dissolving in water with a hissing noise and great development of heat; the solution contains metaphosphoric acid: $P_2O_5 + H_2O = 2HPO_3$; but this acid gradually combines with a further quantity of water, forming phosphoric acid: $HPO_3 + H_2O = H_3PO_4$. By virtue of its affinity to water, phosphoric anhydride causes the separation of the elements of water from many compounds; sulphuric acid, for example, when heated with phosphoric anhydride is converted into sulphuric anhydride—

Oxyacids of Phosphorus.

The following oxyacids of phosphorus are known:—

Hypophosphorous acid	HPH_2O_2
Phosphorous acid	H_2PHO_3
Phosphoric acid	H_3PO_4
Metaphosphoric acid	HPO_3
Pyrophosphoric acid	$H_4P_2O_7$

Hypophosphorous acid, HPH_2O_2 .—To prepare this acid a solution of barium hypophosphite is treated with exactly sufficient sulphuric acid to precipitate the barium, and concentrated until its boiling point rises to $130^\circ C$.; on the liquid cooling, a mass of crystals of the acid is obtained. The solution of the barium salt is obtained by warming (not boiling) phosphorus with an excess of a solution of barium hydroxide, and afterwards removing the excess of hydroxide by passing carbon dioxide through the liquid:—

Hypophosphorous acid melts at $17^\circ C$.; it is perfectly stable at ordinary temperatures, but its solution is slowly oxidized to phosphorous and phosphoric acids when exposed to the air. It is a powerful reducing agent, precipitating silver and gold from solutions of their respective salts, and when heated to about $60^\circ C$. with a solution of copper sulphate it forms a precipitate of copper hydride, Cu_2H_2 . When zinc is dissolved in the acid, the hydrogen produced reduces a portion of the acid to phosphine, which is given off as gas.

Hypophosphorous acid is a monobasic acid. Its salts are crystallizable and soluble in water. They are permanent when dry, but their solutions are gradually oxidized on exposure to the air, especially if heated. When boiled with alkaline hydroxides they are decomposed into phosphate and hydrogen, thus—

The dry salts are decomposed by heat, and in most cases furnish a residue of pyrophosphate and metaphosphate, phosphine and hydrogen being evolved, and sometimes water produced; the proportions in which these products are formed is not constant, and depends on the nature of the salt, thus—

The behaviour of the nickel and cobalt, and uranyl salts is peculiar, a phosphide being also formed—

Phosphorous acid, H_2PHO_3 .—This acid is most readily prepared by decomposing phosphorus trichloride with water. By concentrating the solution by boiling until the temperature rises to $180^\circ C$., and then cooling, it is obtained in the crystalline state. The crystals melt at $70^\circ C$. Like hypophosphorous acid, it is resolved into phosphine and phosphoric acid when heated. Its solution is oxidized on exposure to the air. It is a powerful reducing agent, precipitating silver, gold, and mercury from their salts, but it does not form copper hydride with copper sulphate. Iron and zinc dissolve in a solution of phosphorous acid with evolution of phosphine, a portion of the acid being reduced by the hydrogen resulting from the conversion of another portion into the metallic salt.

Phosphorous acid is a dibasic acid, the salts produced on neutralizing its solution with alkaline hydroxide being formed by the displacement of at most two atoms of hydrogen by metals; thermochemical investigation also indicates that it is a dibasic acid. It is possible, however, to displace a third atom of hydrogen by metals, and to produce such a compound as Na_3PO_3 , for example, but this cannot exist in presence of water. Many of the phosphites apparently must be regarded not as derived from the acid H_2PHO_3 , but as derivatives of a distinct acid of the composition $H_2P_2H_4O_7$, or $2H_2PHO_3 + H_2O$; barium phosphite dried at 200° – $250^\circ C$., for instance, has the composition $Ba_3P_2H_4O_7$.

The phosphites are much more stable than the hypophosphites, but are all decomposed by heat. Salts, such as the barium salt $Ba_3P_2H_4O_7$, furnish hydrogen and pyrophosphate on ignition—

but the normal phosphites, such as zinc phosphite $ZnPHO_3$, furnish hydrogen, a pyrophosphate, and a phosphide—

Phosphoric acid, H_3PO_4 .—This acid may be produced by oxidizing phosphorus with nitric acid, by the oxidation of hypophosphorous and phosphorous acids, by the action of water on phosphoric anhydride and on phosphorus pentachloride, and by decomposing its salts with acids,—tricalcium phosphate or bone earth, for example, with sulphuric acid.

It may be obtained in crystals by concentrating an aqueous solution by boiling until the temperature rises to $215^\circ C$., and when the liquid is cold adding a few crystals, which cause it to solidify.

The crystals melt at about $38^\circ C$. They are readily soluble in water, and furnish a strongly acid solution, which at a boiling heat decomposes the salts of most volatile acids.

Phosphoric acid is a tribasic acid, and furnishes three classes of salts, of which the three sodium salts

NaH_2PO_4 ,	Na_2HPO_4 ,	Na_3PO_4
Sodium dihydrogen phosphate.	Disodium hydrogen phosphate.	Trisodium phosphate.

may serve as examples. It has a great tendency, however, to furnish dimetallic salts, such as Na_2HPO_4 , which are always produced when a solution of phosphoric acid is neutralized with a metallic carbonate (see p. 488).

Metaphosphoric acid, HPO_3 .—This acid is the product of the action of water on phosphoric anhydride, and is also obtained by heating phosphoric acid to redness, and by decomposing the metaphosphates with another acid.

Metaphosphoric acid in the solid state, as obtained by evaporating its solution and heating the residue to redness, is a colourless, glassy, uncrystallizable mass, which dissolves slowly though somewhat abundantly in water, forming a strongly acid liquid; but the solution is very unstable, and is converted gradually at ordinary temperatures, and rapidly on heating, into phosphoric acid. Metaphosphoric acid is an extremely stable body; it volatilizes completely at a bright red heat, and apparently is only in part decomposed into water and phosphoric anhydride.

The metaphosphates, or salts of metaphosphoric acid, which may be produced by heating the monometallic salts of phosphoric acid, for example—

and in various other ways, are remarkable for exhibiting very different properties according to the manner in which they are prepared. Thus, ordinary sodium metaphosphate, obtained by igniting sodium phosphate and sudden cooling, forms a vitreous mass, the aqueous solution of which gives gelatinous precipitates with the salts of the heavy metals. But when a considerable quantity of ordinary fused sodium metaphosphate is allowed to cool very slowly, a crystalline mass results, and on digesting this in a slight excess of warm water the liquid separates into two layers, one containing a crystalline sodium metaphosphate, and the other the ordinary vitreous salt. By heating copper oxide and a slight excess of phosphoric acid together to 350° C., a crystalline powder is formed, insoluble in water; and by treating this copper salt with sodium sulphide another crystalline sodium metaphosphate is produced. If oxide of lead be employed, and the resulting lead salt decomposed with sodium sulphide, a sodium metaphosphate is obtained which forms with water a gummy mass, which will not pass through a filter. Lastly, a fifth variety of metaphosphates, remarkable for their insolubility in water, are formed by adding phosphoric acid in excess to solutions of sulphates or nitrates, evaporating to dryness, and heating the residue to 316° C. or upwards. They are crystalline powders.

These different metaphosphates are generally regarded as polymeric compounds, that is to say, as compounds having different molecular weights although of the same empirical composition; and the attempt has been made to infer their formulæ from the relative number of atoms of the two metals contained in the mixed salts derived from them. Thus, the sodium in ordinary sodium metaphosphate may be partially displaced by another metal, and a mixed salt produced containing the two metals in the ratio of 5 atoms of the one monad metal to 1 atom of the other; hence it is concluded that ordinary sodium metaphosphate is a hexmetaphosphate, $\text{Na}_5\text{P}_6\text{O}_{18}$. The mixed salts derived from the second variety of sodium metaphosphate above described contain the two metals in the ratio of 2 atoms of the one monad metal to 1 atom of another, and are therefore regarded as trimetaphosphates, the sodium salt being represented by the formula $\text{Na}_2\text{P}_3\text{O}_9$. The mixed salts formed from the third and fourth varieties contain equal numbers of atoms of the two metals, and it is therefore supposed that they are respectively di- and tetra-metaphosphates, and that their sodium salts, for example, have the composition $\text{Na}_2\text{P}_2\text{O}_6$ and $\text{Na}_4\text{P}_4\text{O}_{12}$. The insoluble crystalline metaphosphates are regarded as monometaphosphates.

Pyrophosphoric acid, $\text{H}_4\text{P}_2\text{O}_7$.—The normal salts of this acid, which is tetrabasic, may be produced by igniting the dimetallic phosphates; for example—

A solution of the acid may be prepared by decomposing

lead pyrophosphate suspended in water by hydrogen sulphide. Apparently the acid has not yet been obtained in a pure state.

Pyrophosphoric acid is converted into metaphosphoric acid when heated to redness, and into phosphoric acid when boiled with water; the latter change, it is stated, takes place also at ordinary temperatures, but very slowly. A solution of pyrophosphoric acid does not precipitate albumen or silver nitrate, but after neutralization it gives a white precipitate with the latter. Metaphosphoric acid coagulates albumen, and gives a white precipitate with silver nitrate; and phosphoric acid does not coagulate albumen, and when neutralized gives a yellow precipitate with silver nitrate.

In addition to the normal pyrophosphates, acid salts may be obtained, formed by the displacement of only one, two, or three of the four atoms of hydrogen in the acid by metals. By fusing together sodium pyrophosphate and sodium metaphosphate the salts $\text{Na}_3\text{P}_4\text{O}_{13}$ and $\text{Na}_{12}\text{P}_{10}\text{O}_{31}$ have been obtained; these salts may be regarded as formed from acids derived respectively from four and ten molecules of phosphoric acid by the abstraction of the elements of three and nine molecules of water in the same way that pyrophosphoric acid is derived from two molecules of phosphoric acid, by the abstraction of the elements of a single molecule of water—

These acids are terms in a series, of which pyrophosphoric acid is the first member, formed by the withdrawal of the elements of $n - 1$ molecules of water from n molecules of phosphoric acid.

Very little attention has been paid as yet to the thermochemical investigation of the phosphorus compounds. The results obtained by Andrews and by Thomsen are collected in the following table; the numbers all refer to phosphorus in its ordinary state:—

Reaction.	Units of heat evolved or absorbed.	Remarks.
(P, Cl ₂).....	75,000	Andrews.
(P ₂ , O ₅).....	362,800	Abria.
	367,800	Andrews.
(PO ₄ H ₃ , Aq).....	2,690	Heat of solution of the crystalline acids.
(PO ₃ H ₃ , Aq).....	-130	
(PO ₂ H ₃ , Aq).....	-170	
(P, O ₄ , H ₃)	5,210	Heat of solution of the fused acids at the same temperature. The difference between the heat of solution of the fused and crystalline acids is the heat of fusion.
(P, O ₃ , H ₃)	2,940	
(P, O ₂ , H ₃)	2,140	
(P, O ₄ , H ₃)	302,600	Formation of the crystalline acids from their elements.
(P, O ₃ , H ₃)	227,700	
(P, O ₂ , H ₃)	139,970	
(P, O ₄ , H ₃)	300,080	Formation of the fused acids from their elements.
(P, O ₃ , H ₃)	224,630	
(P, O ₂ , H ₃)	137,660	
(P, O ₄ , H ₃ , Aq).....	305,290	Formation of the acids in aqueous solution from their elements.
(P, O ₃ , H ₃ , Aq).....	227,570	
(P, O ₂ , H ₃ , Aq).....	139,800	
(P ₂ , O ₅ , Aq)	405,400	Formation of the acids from phosphorus, oxygen, and water.
(P ₂ , O ₃ , Aq)	250,060	
(P ₂ , O, Aq)	74,520	

Sulphides and Sulpho-Acids of Phosphorus.

The compounds P_4S_3 , P_2S_3 , and P_2S_5 are readily produced by carefully heating together sulphur and red amorphous phosphorus in the required proportions. It is stated that the lower sulphides P_4S and P_2S may also be obtained by melting together ordinary phosphorus and sulphur under hot water in the proportions indicated by these formulæ.

and that both are liquid compounds. The sulphides P_2S_3 , P_2S_4 , and P_2S_5 may be crystallized from their solutions in carbon disulphide; they all exhibit acid properties, dissolving readily in solutions of the metallic sulphides, forming salts of sulpho-acids of phosphorus, which have been little studied, however, on account of their instability. They also dissolve in solutions of the alkaline hydroxides and carbonates, forming salts of oxy-sulpho-acids of phosphorus; but these are also very unstable bodies, and readily decompose in contact with water. The sulphides of phosphorus are readily decomposed by water alone, their sulphur being displaced by oxygen and corresponding oxy-acids of phosphorus produced, the sulphur being separated as hydrogen sulphide; thus—

By heating amorphous phosphorus with selenium in various proportions, the selenides P_2Se_3 , P_2Se_4 , P_2Se_5 , and P_2Se_6 are produced. They resemble the corresponding sulphides, and also exhibit acid characters, combining with metallic selenides to form salts of seleniophosphoric acids, which are even less stable than the corresponding sulpho-salts.

Oxy- and Sulpho-Haloid Compounds of Phosphorus.

We have already pointed out that phosphorus pentachloride and bromide are converted by water into phosphorus oxychloride, $POCl_3$, and phosphorus oxybromide, $POBr_3$. Phosphorus oxychloride may also be obtained by the direct combination of phosphorus trichloride with oxygen, being produced on passing oxygen through the boiling trichloride; it is a colourless mobile liquid at ordinary temperatures, but solidifies on cooling to a mass of crystals, which melt at $2^\circ C.$; it boils at $116^\circ C.$ The oxybromide is a similar compound; its crystals melt at $46^\circ C.$, and it boils at $155^\circ C.$

The oxides of phosphorus do not combine with the halogens, but by the action of nitric peroxide on phosphorus trichloride an oxychloride of phosphorus is formed, which bears the same relation to pyrophosphoric acid that phosphorus oxychloride or phosphoric chloride bears to phosphoric acid—

Pyrophosphoric chloride, as this compound may be termed, is a colourless liquid, which boils between 210° and $215^\circ C.$, but decomposes partially into phosphoric chloride and phosphoric anhydride: $2P_2O_5Cl_4 = 4POCl_3 + P_2O_5$. It is immediately decomposed by water, producing hydrochloric and phosphoric acids.

Phosphorus sulphochloride or sulphophosphoric chloride, $PSOCl_3$, and sulphophosphoric bromide, $PSOBr_3$, are obtained on heating phosphorus trichloride and tribromide with sulphur, and by the action of hydrogen sulphide on the pentachloride and pentabromide of phosphorus: $PCl_5 + H_2S \rightarrow PSOCl_3 + 2HCl$. The sulphochloride is an oily liquid, having an intensely pungent odour, and boils at $126^\circ C.$ The sulphobromide crystallizes; it is partially decomposed on distillation into sulphur and the compound $PSBr_3$, PBr_5 . They are only slowly decomposed by water, the sulphobromide even forming a crystalline hydrate with water, $PSBr_3 \cdot H_2O$; the decomposition of the sulphochloride is represented by the following equations—

The sulphobromide apparently is first converted into mono-sulphophosphoric acid: $PSBr_3 + 3H_2O \rightarrow P(SO_2H)_3 + 3HBr$, which is then resolved partly into sulphur and phosphorous acid, and partly, by the action of the water, into phosphoric acid and hydrogen sulphide. Phosphorus sulpho-

chloride behaves in a similar manner when heated with a solution of sodium hydroxide; thus—

A sulphopyrophosphoric bromide, $P_2S_3Br_4$, corresponding to pyrophosphoric chloride, is formed by directly combining bromine with the sulphide P_2S_3 . It is an oily liquid, which cannot be distilled, being resolved by heat into phosphorus pentasulphide and phosphoric bromide: $3P_2S_3Br_4 = P_2S_5 + 4PSBr_3$.

Constitution of the Phosphorus Compounds.

The formulae of the two chlorides and of the tetrachloride of phosphorus may be given in illustration of the constitution of the compounds of phosphorus with monad elements—

Phosphorus trichloride. Phosphorus pentachloride. Phosphorus triiodide.

The two oxychlorides of phosphorus are represented by the following formulae, the corresponding bromine and sulphur compounds, of course, being similarly constituted:—

Phosphoric chloride.

Pyrophosphoric chloride.

The constitution of the oxides is expressed by the formulae—

Phosphorus anhydride.

Phosphoric anhydride.

Similar formulae are assigned to the corresponding sulphides. Hypophosphorous, phosphorous, and phosphoric acids may be regarded as derived from the compound POH_3 , or phosphine oxide, by the displacement of one, two, and three atoms of hydrogen by the monad radicals OH ; although this compound is not known at present, analogous bodies are readily obtained on oxidizing the substituted phosphines formed by displacing the hydrogen in phosphine by positive monad compound radicals, such as methyl, CH_3 —

Hypophosphorous acid.

Phosphorous acid.

Phosphoric acid.

The relation of meta- and pyrophosphoric acid to phosphoric acid will be evident from the following formulae—

Metaphosphoric acid.

Pyrophosphoric acid.

BORON.

Symbol, B; At. wt., 11; Valency, III.

This element always occurs in the combined state as boric acid, or as a salt of boric acid. Two modifications of boron may be obtained, viz., an amorphous and a crystalline modification; the former is produced by reducing boric anhydride, B_2O_3 , by heating it with sodium, and the latter is formed when the reduction is effected by the aid of aluminium at a very high temperature.

Amorphous boron is a dark brown powder; it does not oxidize in the air at ordinary temperatures, but when heated it burns in air or oxygen, in the latter with dazzling brightness, forming the oxide B_2O_3 . By ignition in an atmosphere of nitrogen it is converted into a white amorphous boron nitride, BN. It does not decompose water, even at the boiling heat, but readily dissolves in nitric acid, producing boric acid; when heated with potassium hydroxide it forms a potassium borate, hydrogen being evolved.

On heating amorphous boron with aluminium it is dissolved, and crystallizes from the fused metal on cooling; it may be separated from the latter by the aid of hydrochloric acid. The crystals are usually of a more or less brown colour, but in lustre, refracting power, and hardness they are nearly equal to the diamond. Crystalline boron is only slightly oxidized at the temperature at which diamond burns.

Boron forms a trichloride, BCl_3 , a tribromide, BBr_3 , and a trifluoride, BF_3 . The chloride may be obtained by the direct action of chlorine on amorphous boron, the combination taking place at ordinary temperatures; it is also produced by strongly heating a mixture of boric anhydride and charcoal in an atmosphere of chlorine, and by heating boric anhydride with phosphorus pentachloride to $150^\circ C$. The bromide may be obtained in a similar manner by the direct combination of its elements. Both are colourless, mobile liquids; the chloride boils at $17^\circ C$, and the bromide at $90^\circ C$. They are readily decomposed by water; thus—

Boron chloride is not easily deprived of its chlorine by the action of metals, which is apparently accounted for by the fact that much heat is evolved in its formation from its elements. According to Troost and Hautefeuille, the amounts of heat disengaged in the formation of the chloride and oxide of boron from their elements, and in the decomposition of the former by a large excess of water, are as follows—

(B, Cl_3)	= 104,000	units of heat.
(B_2 , O_3)	= 317,200	" "
(BCl_3 , Aq)	= 79,200	" "

Boron fluoride is formed by the action of hydrofluoric acid on boric anhydride, viz., by heating a mixture of boric anhydride and calcium fluoride with concentrated sulphuric acid. It is a colourless gas, of pungent, suffocating odour; when passed into water, which dissolves about 700 times its volume of the gas, it is partly decomposed into boric and hydrofluoric acids, and partly combines with the hydrofluoric acid thus produced, forming fluoboric acid, $HF \cdot BF_3$. This acid can only be obtained in a state of dilute solution, but many salts formed from it are known, such as potassium borofluoride, KBF_4 , for example. Its existence appears to indicate that boron is capable of acting as a pentad element.

Boron oxide, B_2O_3 , is most readily obtained by strongly heating boric acid; it forms a colourless, brittle, glassy mass, which dissolves readily in water, producing boric acid, and is one of the most stable oxides known. It

unites with metallic oxides, when fused with them, forming borates, and at high temperatures it is capable of decomposing carbonates, sulphates, and indeed the salts of all acids the anhydrides of which are more volatile than itself.

Boric acid, H_3BO_3 or $B(OH)_3$, occurs native in many volcanic districts, especially in Tuscany, where it issues from the earth together with vapour of water; borax, $Na_2B_4O_7 \cdot 10H_2O$, and a few other of its salts are also found in nature. It crystallizes from water in white laminae, which are easily soluble; when heated to about $100^\circ C$, it furnishes a residue of the composition $H_4B_2O_6$, which, on heating to $160^\circ C$, becomes $H_2B_4O_7$, and at a stronger heat it is converted into the anhydride, B_2O_3 . A large number of borates are known, but the nature of their relation to boric acid is not well understood. A comparatively small number are derived from the acid H_3BO_3 , the majority apparently being formed from an acid of the empirical composition HBO_2 , to which the name metaboric acid is given. Salts derived from the acids $H_6B_4O_9$ and $H_2B_4O_7$ are also known, and ordinary borax, the most important of the borates, may be regarded as formed from the latter acid.

CARBON.

Symbol, C; At. wt., 11.97; Valency, IV.

The properties of carbon itself and its oxides have already been described (p. 86), and need not therefore be again discussed.

On comparing the compounds of carbon with those of other elements we find that, whereas there is reason to believe that the number of atoms of any of the other elements directly associated together in a molecule of their compounds is very small, probably never exceeding five, carbon compounds frequently contain a relatively very large number of carbon atoms, which from the behaviour of the compounds we are led to suppose are in direct association with each other; and while none of the remaining elements are known to furnish more than a single stable compound with hydrogen, the number of stable compounds of carbon with hydrogen which have been obtained may be counted by hundreds. We are thus led to the conclusion that carbon possesses two distinctive properties:—firstly, that of uniting with itself to an almost unlimited extent in comparison with other elements; and secondly, that of combining with hydrogen in numerous proportions. It is in consequence capable of uniting with the same elements in a multiplicity of proportions, and of furnishing a great variety of compounds, which probably exceed in number those of all the remaining elements together.

The study of the compounds of carbon constitutes that branch of our science which is termed organic chemistry, which is treated separately below, pp. 514 *seq.*;—the study of the remaining elements and of their compounds constituting inorganic or, as it is also termed, mineral chemistry. The division is both useful and necessary, on account of the great number of carbon compounds which exist, and because, generally speaking, the compounds of other elements are distinguished from those of carbon by their comparative simplicity, and also by the comparative want of stability which all but the simplest exhibit; this we may attribute to the possession by carbon of the distinctive properties above mentioned, but otherwise there is no essential difference between the compounds of carbon and those of the remaining elements.

Organic chemistry originally dealt only with substances more or less directly derived from the animal or vegetable kingdom, and it was long believed that the chemist was

powerless to produce organic substances from their elements as they were formed in the animal or plant under the influence of life, it being supposed that, therefore, the interposition of a special force, termed the vital force, was requisite. The first step towards the disproof of this hypothesis was made by Wöhler, who in 1828 succeeded in artificially producing urea, the characteristic crystalline constituent of the urine; but its final overthrow was not accomplished until 1845, when Kolbe showed that it was possible to produce acetic acid from carbon by a comparatively very simple series of reactions. Berthelot's discovery in 1862 of the formation of acetylene, C_2H_2 , from its elements, however, affords the simplest solution of the problem of the artificial production of organic substances from their elements, as acetylene may be without difficulty converted into ordinary alcohol, and from this body all the carbon compounds which have been artificially prepared may be more or less directly derived. Chemists have already succeeded in preparing a large number of substances which occur as products of animal or vegetable life,—for example, oxalic, tartaric, and salicylic acids; coumarin, the crystalline substance from which the Tonka bean derives its pleasant odour; and alizarin, the colouring matter derived from madder root. From the insight we have recently gained into their constitution, there is little doubt that eventually the synthesis of even the most complex organic bodies, such as albumen, will be possible.

Although carbon combines with hydrogen in a great variety of proportions, it furnishes only a very limited number of compounds with other elements; thus, only one sulphide of carbon, CS_2 , and one nitride of carbon, C_2N_2 , are known, and no well characterized compounds of carbon with the metals have been obtained. The compounds of carbon with the halogens are more numerous. The only compound that calls for consideration here is the sulphide; the others will be noticed in the section on Organic Chemistry.

Carbon disulphide, CS_2 , the analogue of carbon dioxide, is obtained by passing sulphur vapour over charcoal heated to redness. It is a colourless, very mobile, highly refracting liquid of faint unpleasant odour, insoluble in water; it boils at $46^\circ C$. It is extremely inflammable, and its vapour when mixed with air is highly explosive; the products of its combustion are carbon dioxide and sulphur dioxide. The formation of carbon disulphide from its elements is attended with the absorption of no less than 22,000 units of heat, which explains how it is that it so readily inflames, and also the fact that it is necessary to apply heat continuously in preparing it; whereas the combustion of carbon in oxygen, when once it commences, proceeds spontaneously, owing to the large amount of heat developed in the process; we may suppose that the expenditure of energy is necessary because less heat is developed by the combination of the atoms of carbon and sulphur than is requisite to convert the carbon and sulphur from the state in which they ordinarily exist into that in which they exist in carbon disulphide, or, in other words, than is requisite to effect the separation from each other of the atoms of carbon and of sulphur in the carbon and sulphur molecules.

Carbon disulphide belongs to the class of acid sulphides or sulphur-anhydrides. It readily dissolves in solutions of alkaline hydroxides and of metallic sulphides, forming salts analogous to the metallic carbonates, and which may be regarded as derived from the carbonates by the partial or entire displacement of the oxygen in the latter by sulphur. The stability of these salts and of the corresponding acids increases with the amount of sulphur; thus, sulphocarbonic acid, H_2CS_3 , which is formed from the salt produced by combining carbon disulphide with metallic

sulphides, may be obtained as a yellow oily liquid, whereas carbonic acid, H_2CO_3 , can only exist in extremely dilute solution.

Carbon disulphide readily dissolves sulphur and phosphorus, and also oils and fatty matters; on this account it meets with many practical applications.

By gently heating a mixture of carbon disulphide and sulphuric anhydride, carbon oxysulphide is produced, one-half the sulphur in the former being displaced by oxygen: $CS_2 + SO_3 = COS + SO_2 + S$; this compound may also be obtained by combining carbon monoxide with sulphur, by passing a mixture of the gas with sulphur vapour through a red hot tube. It is a colourless gas, possessing an odour like that of carbon disulphide; in properties, as in composition, it is intermediate between carbon dioxide and disulphide.

SILICON.

Symbol, Si; At. wt., 28; Valency, 4.

This element always occurs in combination either with oxygen alone as silicon dioxide or silica, or with oxygen and metals as silicates,—constituting, in fact, in these forms of combination, the greater part of the earth's crust.

Silicon may be obtained from its chloride or fluoride by the action of metals such as potassium, sodium, or aluminium; like carbon it exists in three distinct modifications. *Amorphous silicon* produced by heating potassium silicofluoride, K_2SiF_6 , with potassium, or the corresponding sodium salt with sodium, is a dull brown powder, heavier than water; it is not affected by nitric or sulphuric acid, but is readily dissolved by hydrofluoric acid, and by a warm aqueous solution of potassium hydroxide. It fuses at a temperature below that at which steel melts; and when heated in air or oxygen it burns brilliantly and is converted into silicon dioxide. When strongly heated in a platinum crucible it becomes much denser and darker in colour, and much less oxidizable, being converted into *graphitoid silicon*. On heating a mixture of aluminium with potassium silicofluoride to the melting point of silver, a metallic button is obtained, which, when treated successively with hydrochloric and hydrofluoric acids, yields graphitoid silicon partly in isolated hexagonal tables. This modification has the specific gravity 2.49, and may be heated to whiteness in oxygen without burning; it is not attacked by any acid excepting a mixture of nitric and sulphuric acids, and is only slowly dissolved by a solution of potassium hydroxide.

When the vapour of silicon tetrachloride mixed with hydrogen is passed over fused aluminium, the chloride is reduced, and the silicon dissolves in the aluminium; after a time a point is reached at which the silicon separates from the fused metal in large beautiful needles, having a dark iron-grey colour. These crystals constitute the *adamantine* variety of silicon.

Silicon appears to be capable of combining with hydrogen in the nascent state, as when a plate or wire of aluminium containing silicon is connected with the positive pole of a galvanic battery, and made to decompose a solution of sodium chloride, gas is evolved which spontaneously inflames. Silicon hydride mixed with much hydrogen is also obtained on decomposing with concentrated hydrochloric acid the magnesium silicide produced by heating a mixture of magnesium chloride, sodium silicofluoride, and sodium chloride with sodium. It is produced by the decomposition of triethylsilane in contact with sodium—

Triethylsilane orthoformate. Silicon hydride. Tetraethylorthosilicate.

It is a colourless gas, not spontaneously inflammable under the ordinary temperature or pressure, but only when gently heated under reduced pressure, or when mixed with

hydrogen. When heated by itself, it is decomposed into amorphous silicon and free hydrogen. It is insoluble in water, and is not altered by dilute hydrochloric or sulphuric acid; potassium hydroxide, however, decomposes it readily—

It precipitates silicide of copper from a solution of copper sulphate, and metallic silver mixed with a black substance, which is, perhaps, silver silicide, from a solution of silver nitrate.

By heating silicon in chlorine gas, or in an atmosphere of bromine, or iodine, it is converted into the compounds SiCl_4 , SiBr_4 , and SiI_4 ; the chloride and bromide are best prepared, however, by passing chlorine or bromine vapour over an intimate mixture of silica and charcoal heated to redness. Silicon tetrachloride and tetrabromide are colourless liquids, boiling at 50°C . and 153°C . respectively; the tetriodide crystallizes from its solution in carbon disulphide in colourless octahedra (which melt at $120^\circ\!5 \text{C}$.), and boils at about 290°C ., distilling without alteration in a stream of carbon dioxide. They are quickly decomposed by water; thus—

When silicon tetriodide is heated to near its boiling point with finely divided metallic silver it is converted into disilicon hexiodide, Si_2I_6 ; this crystallizes from carbon disulphide in colourless hexagonal prisms which are decomposed on fusion into the tetriodide and a body which is perhaps the subiodide, Si_3I_4 . By the action of bromine, this compound is converted into the corresponding bromide, Si_2Br_6 , and by gently heating it with mercuric chloride the chloride Si_2Cl_6 is obtained. The bromide forms crystals which distil without decomposition at about 240°C .; disilicon hexachloride is a colourless mobile liquid, which boils at $146^\circ\text{--}148^\circ \text{C}$., the corresponding carbon chloride, C_2Cl_6 , being a crystalline solid which boils at 330°C .; it is very slowly decomposed when heated in closed vessels to 350°C . into the tetrachloride and silicon, and is entirely converted into these substances at 800°C . A lower liquid chloride, which probably has the composition Si_3Cl_8 , is obtained in small quantity together with the hexachloride when the vapour of the tetrachloride is passed over fused silicon heated to a very high temperature.

By passing the vapour of silicon tetrachloride through an exhausted porcelain tube containing fragments of felspar heated nearly to the fusing point of the latter, it is partially converted into the oxychloride $(\text{SiCl}_3)_2\text{O}$; this is a colourless liquid boiling at $136^\circ\text{--}139^\circ \text{C}$., which is decomposed by water in the same manner as silicon tetrachloride. When the vapour of this compound mixed with oxygen is passed several times through a heated tube, silicon tetrachloride is reproduced, and a complex mixture of higher liquid oxychlorides is obtained containing the compounds $\text{Si}_3\text{O}_2\text{Cl}_8$ (b. p. $152^\circ\text{--}154^\circ \text{C}$.), $\text{Si}_4\text{O}_2\text{Cl}_{10}$ (b. p. about 200°C .), $\text{Si}_5\text{O}_2\text{Cl}_{12}$ (b. p. about 300°C .), together with still higher oxychlorides.

By passing hydrochloric acid over crystallized silicon heated to barely visible redness, a mixture is produced of silicon tetrachloride with the compound SiHCl_3 , which from its relation in composition to trichloromethane or chloroform, CHCl_3 , is termed silicon-chloroform. The corresponding iodo-derivative, SiHI_3 , is formed in a similar manner by the action of hydriodic acid gas mixed with hydrogen. Silicon chloroform is a colourless extremely mobile liquid, and boils at about 36°C .; it is converted by chlorine at ordinary temperatures into the tetrachloride, and when heated with bromine it furnishes silicon trichlorobromide, SiCl_3Br , which boils at 80°C . Silicon

iodoform, SiHI_3 , is a colourless, strongly refracting liquid; it boils at about 220°C .

When a mixture of silicon tetrachloride vapour and hydrogen sulphide gas is passed through a tube heated to redness, the compound SiCl_3SH is obtained; it is a colourless liquid boiling at 96°C .

Hydrofluoric acid acts readily on silicon dioxide and silicious substances generally, forming silicon tetrafluoride: $\text{SiO}_2 + 4\text{HF} = \text{SiF}_4 + 2\text{H}_2\text{O}$. Silicon tetrafluoride is a colourless gas, which liquefies under very strong pressure, and solidifies at -140°C .; it is not inflammable. It is readily absorbed by water, which decomposes it into silica and hydrofluosilicic acid: $3\text{SiF}_4 + 2\text{H}_2\text{O} = 2\text{H}_2\text{SiF}_6 + \text{SiO}_2$. This acid is not known except in solution, but its salts, which are readily produced by neutralizing its solution with metallic oxides, hydroxides, or carbonates, are stable compounds, and are mostly soluble in water. By prolonged ignition they are decomposed into silicon fluoride which escapes, and a metallic fluoride which remains behind. Potassium fluosilicate, K_2SiF_6 , is one of the least soluble of the potassium salts, and consequently this acid is often used to precipitate potassium from solutions of its salts.

By passing the tetrafluoride over silicon heated nearly to the softening point of porcelain, it is converted into a subfluoride, which probably has the composition Si_2F_5 ; it is a white, very light powder.

Only one oxide of silicon is known, viz., the dioxide or silica, SiO_2 . According to Troost and Hautefeuille, its formation from amorphous silicon and oxygen is attended with the development of a very large amount of heat, viz.,—

$$(\text{Si}, \text{O}_2) = 219,240 \text{ units of heat.}$$

According to the same observers, in the formation of the tetrachloride from amorphous silicon and chlorine, and in its decomposition by 140 times its weight of water, the following amounts of heat are developed:—

$$\begin{aligned} (\text{Si}, \text{Cl}_4) &= 157,640 \\ (\text{SiCl}_4, \text{Aq}) &= 81,640 \end{aligned}$$

and from the amount of heat developed on dissolving amorphous and crystallized (? adamantine) silicon in a mixture of nitric and hydrofluoric acids they calculate that the transformation of the former into the latter is attended with the development of 8120 units of heat.

When obtained by igniting the gelatinous silica from the decomposition of the haloid silicon compounds by water, or of the soluble silicates by acids, silica is a snow-white amorphous powder; but it occurs native as quartz in large transparent crystals of the hexagonal system, of the specific gravity 2.5 to 2.8, and of extreme hardness. Native silica of all kinds is insoluble in water and in all acids except hydrofluoric acid; this is also true of artificial ignited silica. The gelatinous hydrate which separates on the addition of acids to solutions of alkaline silicates is also almost insoluble in water and in acids, but that which results from the decomposition of silicon fluoride is stated to be soluble in a considerable quantity of water. Gelatinous silica dissolves without difficulty in solutions of potassium or sodium hydroxide at the ordinary temperature, and all forms of silica are more or less readily dissolved by solutions of these alkalis, especially when heated with them under pressure; in this manner, according to the proportions of silica and alkali employed, various alkaline silicates are formed which are the more soluble the greater the proportion of alkali metal they contain. Those which contain a larger proportion than is indicated by the formula Na_2SiO_3 , but still a sufficient quantity to make them completely soluble in water, are termed "water-glasses;" water-glass is now largely manufactured and employed for hardening and preserving stone,

in the preparation of paints, especially for mural painting, and in the manufacture of soap.

Although silica is an extremely weak acid oxide, on account of its non-volatility, it is capable of decomposing the salts of all volatile acids at more or less elevated temperatures, and the salts formed from it are stable at the highest temperatures. A great variety of artificial and natural silicates are known,—some of which may be regarded as derived from silicic acid, H_2SiO_3 , and others from an acid which may be termed orthosilicic acid, H_4SiO_4 , but the majority are far more complex, those which occur as natural minerals being formed by the association of silica with basic oxides in proportions included between the following limits:—

On adding acids to a solution of an alkaline silicate, a gelatinous "hydrate of silica" is precipitated; the whole of the silica may be retained in solution, however, if a dilute solution of an alkaline silicate be poured into a considerable excess of hydrochloric acid, but may be precipitated by gradually neutralizing the acid. The retention of the silica in solution is, perhaps, due to the formation of a soluble chlorhydrin (p. 565). If a stratum $\frac{1}{16}$ of an inch in depth of the hydrochloric acid solution be placed in a "dialyzer" formed by stretching wetted parchment paper across a light hoop of wood or gutta-percha, and the dialyzer be floated in a vessel of water, the water in the outer vessel being changed at intervals, after four or five days the hydrochloric acid and the soluble chlorides are found to have diffused completely into the water; but the solution in the dialyzer still contains the silica, and a 5 per cent. solution prepared in this way may be concentrated by boiling down in an open flask until it contains nearly 14 per cent. of silica. The solution is tasteless, limpid, and colourless; it has an acid reaction rather greater than that of carbonic acid; for every 100 parts of silica present, however, only 2.13 parts of potassium hydroxide are requisite to neutralize the acid reaction. The solution is not easily preserved for many days, as it becomes converted into a solid transparent jelly; coagulation is retarded by hydrochloric acid, and by small quantities of potassium or sodium hydroxide, but is effected in a few minutes by the addition of $\frac{1}{1000}$ part of any alkaline carbonate, although ammonia and its salts are without effect. Sulphuric, nitric, and acetic acids are also without action, but a few bubbles of carbon dioxide gas slowly cause coagulation. The condition in which the silica is present in the solution having these very remarkable properties is not known, but on the assumption that a chlorhydrin is produced on decomposing the alkaline silicate by an excess of hydrochloric acid, it appears not improbable that, as the excess of the latter is removed by dialysis, the chlorhydrin is gradually decomposed by the water and, perhaps, converted into the hydroxide H_2SiO_3 , or some other soluble hydroxide, and that the subsequent coagulation may be due to the conversion of this hydroxide into an insoluble hydroxide of different molecular composition. The solution evaporated at 15° C. in a vacuum leaves the silica in the form of a transparent, glassy, very lustrous hydrate, containing after two days' exposure over sulphuric acid an amount of water which agrees very nearly with the formula H_2SiO_3 .

When silicon chloroform is added to water at the ordinary temperature, hydrogen is evolved, and hydrated silica is produced: $SiHCl_3 + 2H_2O = H_2 + SiO_2 + 3HCl$; but if water at zero is employed, a precipitate is obtained which, after drying over sulphuric acid, and then at 150° C., has the composition $(HSiO)_2O$. This compound is analogous

in composition to the unknown anhydride of formic acid: $(HCO)_2O = 2HCO(OH) - OH_2$; its formation is probably preceded by that of the hydroxide $SiH(OH)_3$. It is a snow-white, voluminous, amorphous substance, slightly soluble in water; it is decomposed by the least heat when in a moist state, with evolution of hydrogen, and is dissolved by ammonia, caustic alkalis, and alkaline carbonates, with evolution of hydrogen and production of an alkaline silicate. It is not acted upon by any acids except hydrofluoric acid, even concentrated nitric acid being without action. It decomposes when heated above 300° C.

Silicon hexachloride and hexiodide are decomposed by water in a similar manner, being first converted into the hydroxide $Si_2(OH)_6$, which then furnishes siliconoxalic acid $Si_2O_2(OH)_2$. This is a white substance, and when heated is decomposed, like the preceding compound, with evolution of hydrogen, leaving a residue of silica; it is also decomposed with evolution of hydrogen by even the weakest bases. It rapidly reduces potassium permanganate in the cold, but is only slowly oxidized by chromic acid, and is without action on solutions of gold chloride or selenious acid. On decomposing the chloride, Si_2Cl_6 , however, by water an hydrated oxide is obtained which not only reduces potassium permanganate and chromic acid, but also gold chloride and selenious acid. The behaviour of siliconoxalic acid on oxidation is precisely similar to that of its carbon analogue oxalic acid, $C_2O_2(OH)_2$, which, however, is a crystalline, strongly acid body, which dissolves readily in water and furnishes stable salts.

By the action of anhydrous alcohol, silicon tetrachloride is converted into tetraethylorthosilicate, $Si(OC_2H_5)_4$, which is a colourless liquid boiling at 166° C.; it is gradually decomposed by water, being converted into alcohol and gelatinous silica. By the joint action of zinc ethyl and sodium on this compound, it is possible to displace in succession each of the groups (OC_2H_5) by ethyl, thus:—

In this manner the following compounds have been prepared:—

	Boiling Point.
$Si(C_2H_5)(OC_2H_5)_3$	166° C.
$Si(C_2H_5)_2(OC_2H_5)_2$	159°
$Si(C_2H_5)_3(OC_2H_5)$	155°
$Si(C_2H_5)_4$	153°
$Si(C_2H_5)_3H$	107°

These compounds are all colourless liquids, insoluble in water, and stable in the air; the first only is decomposed when allowed to remain in contact with water. Silicon ethyl, $Si(C_2H_5)_3$, may also be obtained by the action of zinc ethyl on silicon tetrachloride; and from the latter compound and zinc methyl silicon methyl, $Si(CH_3)_3$, has been prepared; similarly, the hexiodide is converted into the corresponding ethyl derivative $Si_2(C_2H_5)_6$ by the action of zinc ethyl. These silicon hydrocarbons exhibit the closest resemblance to their analogues the paraffins. Thus by the action of bromine on silicon triethylhydride, $Si(C_2H_5)_3H$, the bromide $Si(C_2H_5)_3Br$ is produced, which may be converted by the action of aqueous ammonia into the silicon alcohol triethylsilicic, $Si(C_2H_5)_3OH$; this method of formation is precisely analogous to that by which the hydrocarbon $C(CH_3)_3H$ is converted into the alcohol $C(CH_3)_3OH$. Triethylsilicic also resembles the corresponding alcohol triethylcarbinol, $C(C_2H_5)_3OH$, in properties; thus, both are colourless, viscid liquids, having a strong camphor-like odour, difficultly soluble in water; the former boils at 154° C., the latter at 141° C.; they dissolve sodium with evolution of hydrogen, being converted into corresponding sodium derivatives $Si(C_2H_5)_3ONa$ and

$C(C_2H_5)_3ONa$; and both are acted upon by acetic chloride in a similar manner—

The most important difference is in their behaviour on oxidation,—triethylsilicic acid remaining unattacked, while triethylcarbinol is readily converted into acids containing fewer atoms of carbon.

Silicon ethyl is converted by the action of chlorine into a chlorinated derivative $Si(C_2H_5)_2(C_2H_4Cl)$, from which the silicon alcohol $SiC_3H_9.OH$ may be prepared, corresponding to the yet unknown carbon alcohol $C_9H_{19}.OH$. It is a liquid insoluble in water, smelling like camphor, and boiling at $190^\circ C$.

By heating the compound $Si(C_2H_5)(OC_2H_5)_2$ with hydriodic acid solution it is converted into silicopropionic acid—

In a similar manner, siliconacetic acid, $CH_3SiO(OH)$, may be prepared from the corresponding methyl compound. But although these silicon acids correspond in composition to acetic acid, $CH_3CO(OH)$, and propionic acid, $C_2H_5CO(OH)$, they exhibit very different properties; thus, they are white amorphous substances, insoluble in water, although soluble in alkaline solutions, from which they are precipitated by the addition of acids, whereas acetic and propionic acids are colourless liquids, soluble in water, and boil respectively at $119^\circ C$. and $140^\circ C$.

When the vapour of carbon disulphide is passed over a heated mixture of silica and carbon, silicon disulphide, SiS_2 , is produced; it crystallizes in white silky needles, which quickly decompose in moist air into hydrogen sulphide and amorphous silica.

From the foregoing description of the silicon compounds, it will be evident that while closely allied both in composition and in many of their properties to the carbon compounds, they nevertheless differ from them in numerous important particulars. Thus, carbon dioxide is gaseous, and silicon dioxide is a non-volatile solid; the chlorides of carbon are stable in presence of water except perhaps at relatively very high temperatures, but the chlorides of silicon are with the greatest readiness decomposed by water; carbon disulphide is a volatile liquid not affected by water, while silicon disulphide is a solid which cannot exist in presence of water; and obviously the representatives of the carbon compounds oxalic acid, acetic acid, and propionic acid in the silicon series possess very different properties. In many respects silicon bears considerable resemblance to boron, the resemblance being especially noticeable between the elements themselves, and in the behaviour of their haloid compounds with water, and also in the property which the fluorides of both elements possess of combining with hydrogen fluoride. It is of interest to note that much more heat is developed in the formation of the oxides of boron and silicon than in the formation of carbon dioxide, which alone is gaseous, thus—

In the case of the corresponding chlorides the order of volatility is reversed; thus—

In discussing the remaining elements it will suffice to indicate the general nature of their relations to each other,

as a full description of the more important will be given under other headings. It will be convenient in the first instance to consider those elements together which are most closely related in properties, and afterwards to indicate the manner in which the elements generally are related to each other.

METALS OF THE ALKALIES.

Name.	Symbol.	At. wt.	Sp. gr.	At. vol.	Melting point. ° C.	Electric conductivity at $20^\circ-21^\circ 5 C$
Lithium	Li	7	.59	11.8	180	19.00
Sodium	Na	23	.97	23.7	97	37.43
Potassium	K	39	.86	45.3	62	20.83
Rubidium	Rb	85.2	1.52	56.0	58	...
Cæsium	Cs	132.7

The elements of this class are white metals, volatile at high temperatures; lithium is softer than lead but harder than sodium, while sodium is harder than potassium, and potassium harder than rubidium, the last mentioned being as soft as wax. They may all be separated from their chlorides by electrolysis, and apparently also by strongly heating mixtures of their carbonates with charcoal in iron retorts; the latter method is employed in the manufacture of sodium and potassium, and rubidium has been prepared by it. Cæsium has not yet been obtained in a pure state, but an amalgam of cæsium may be procured by submitting its chloride to electrolysis, employing a globule of mercury as the negative electrode.

Cæsium is the most electro-positive element yet discovered; the remaining members of the group follow it in this respect in the order of their atomic weights. They are easily fusible (see table above), and their compounds with other elements are all fusible.

The metals of this group and their compounds furnish characteristic spectra, which are distinguished from those of most other elements by their simplicity. Lithium and its salts communicate a beautiful red colour to flame, sodium salts an intense yellow, and potassium, cæsium, and rubidium salts a violet colour.

According to Troost and Hautefeuille, when potassium is heated to $350^\circ-400^\circ C$. in an atmosphere of hydrogen, it is converted into a hydride of the composition K_2H ; and the corresponding hydride, Na_2H , may be prepared in a similar manner from sodium. Lithium, however, manifests but little tendency to combine with hydrogen, absorbing only 17 times its volume of the gas at $500^\circ C$. The hydrides are white bodies resembling silver in appearance; potassium hydride is very brittle, but sodium hydride is as soft as sodium, although it becomes brittle when heated; the former takes fire spontaneously in air, but the latter is much more stable. The compounds of lithium, sodium, and potassium with hydrocarbon radicles are only known in combination with the zinc compounds; thus, the body obtained by the action of sodium on zinc ethyl has the composition $ZnNa(C_2H_5)_2$.

The haloid compounds of the elements of this group may be formed by the direct combination of the metals with halogens; their affinity for halogens, however, appears to be inversely proportional to their atomic weights. Thus, it is requisite to heat sodium to a moderately high temperature in an atmosphere of chlorine in order to secure its conversion into the chloride $NaCl$; but potassium inflames in chlorine at the ordinary temperature. Similarly, sodium may be preserved unchanged in contact with bromine, and is scarcely affected even when heated with it to $200^\circ C$; potassium, however, causes a violent explosion when thrown on bromine. Sodium may also be fused with iodine without appreciable reaction occurring, but potassium at once combines with it with explosive violence.

The metals of this group all decompose water in the cold with evolution of hydrogen and production of a solution of the hydroxide: for example—

Lithium does not fuse when thrown on water, and sodium fuses but does not inflame; potassium and rubidium, however, not only fuse but also take fire and burn with a violet coloured flame. According to Thomsen's determinations, more heat is developed in the decomposition of water by lithium or sodium than by potassium; thus—

(Li, Aq) = 49,080 units of heat.

(Na, Aq) = 48,100 "

(K, Aq) = 43,450 "

The difference in their behaviour when thrown on water is, perhaps, due to the circumstance that the action proceeds more rapidly with potassium than with sodium.

All the metals of this group attract oxygen with avidity on exposure to air, but lithium is much less oxidizable than sodium or potassium, rubidium takes fire spontaneously in air, and cesium amalgam in much more readily oxidized than rubidium amalgam; so that their affinity for oxygen, as for the halogens, is proportional to their atomic weights. Only one oxide of lithium, Li_2O , has been obtained, but two oxides of sodium, Na_2O , and Na_2O_2 , and three oxides of potassium, K_2O , K_2O_2 , and K_2O_4 , are known; the oxides of the remaining elements have not been investigated. The oxides of the form $\text{M}'_2\text{O}$ are white deliquescent solids, which readily dissolve in water with the development of much heat, forming solutions of the corresponding hydroxides, M'.OH ; they are the most powerfully basic oxides known. The oxides of the form $\text{M}'_2\text{O}_2$ dissolve in water, but corresponding salts are unknown; potassium tetroxide dissolves in water with evolution of oxygen. The hydroxides M'.OH , or alkalis, are white fusible solids of remarkable stability, volatilizing at high temperatures apparently without undergoing decomposition; they are very soluble in water, furnishing strongly alkaline solutions, soapy to the touch.

The metals of the alkalis appear to act uniformly as monads, and the salts derived from them are all formed on the typea M'Cl , $\text{M}'_2\text{SO}_4$, &c. Their salts are colourless excepting those derived from coloured acids; and the corresponding salts of the several metals are isomorphous. Their chlorides, carbonates, sulphates, and phosphates are soluble in water, and the chlorides and sulphates furnish neutral solutions. Their sulphites form characteristic double salts called "alum" with sulphate of aluminium and the sulphates of allied elements. The alums all crystallize with the same number of molecules of water, and correspond in composition to ordinary alum, $\text{K}_2\text{Al}_2(\text{SO}_4)_3 \cdot 24\text{H}_2\text{O}$; they are also isomorphous.

Although the general resemblance between the metals of this group is very great, it will be obvious that they differ in many important respects. The properties of potassium, rubidium, and cesium, which are very closely related, are especially different from those of lithium and sodium, which are also closely related. For instance, the normal lithium and sodium salts of chloroplatinic acid, H_2PtCl_6 , the acid lithium and sodium salts of tartaric acid, $\text{H}_2\text{C}_4\text{H}_4\text{O}_6$, and the lithium and sodium alums are readily soluble in water, whereas the corresponding salts of potassium, rubidium, and cesium are difficultly soluble. Lithium, however, in many of its properties is more closely allied to magnesium and calcium than to sodium; and it may be noticed that its chloride, like that of magnesium, dissolves in water with considerable development of heat.

The reactions involved in the formation of a few compounds of lithium, sodium, and potassium have been investigated by Thomsen, with the following results:—

METALS OF THE ALKALINE EARTHS.

Name.	Symbol.	At. wt.	Sp. gr.	At. vol.	Electric conductivity at 20° C.
Calcium	Ca	39.9	1.57	25.4	22.14
Strontium	Sr	87.2	2.50	31.8	6.71
Barium	Ba	136.8	3.6	34.2	..

The members of this group are strongly positive elements, which act uniformly as dyads; the relations between them are similar to those which obtain in the preceding group, the element with the highest atomic weight being the most positive. Strontium, however, in some respects appears to be more closely related to barium than to calcium. They are best prepared by the voltaic decomposition of their fused chlorides; their chlorides are not reduced by sodium, but calcium may be obtained by heating calcium iodide with sodium.

Calcium is a yellow metal of the colour of gold largely alloyed with silver; in hardness it is intermediate between lead and gold, and it is very ductile. It melts at a red heat. Strontium closely resembles calcium, but has a deeper colour; little is known of barium, but it appears to resemble strontium and calcium. The behaviour of these elements with halogens is apparently similar to that of the metals of the preceding group with low atomic weights.

They decompose cold water with evolution of hydrogen, but less readily than the alkali metals; it is remarkable that concentrated nitric acid is almost without action on calcium and strontium even when heated to boiling, although the diluted acid dissolves them rapidly.

They are less easily oxidized than the alkali metals, calcium being the least, and barium apparently the most oxidizable; in dry air calcium and strontium remain untarnished for a considerable period. They burn with great brilliancy when ignited in air.

Each metal furnishes two oxides,—a monoxide such as barium oxide, BaO , and a dioxide such as barium peroxide, BaO_2 ; these oxides are white, earthy, infusible substances; the dioxides are decomposed into the monoxides and oxygen at a red heat. Their monoxides are powerfully basic, but apparently the dioxides are almost destitute of basic properties; the action of acids on the two classes of oxides is illustrated by the following equations:—

Barium monoxide is converted into the dioxide when heated to dull redness in an atmosphere of oxygen, but the dioxides of strontium and calcium cannot be prepared in this manner. By the action of water the monoxides are converted with development of much heat into the corresponding hydroxides, which are strongly alkaline. Barium hydroxide, Ba(OH)_2 , is dissolved by water, although to a less extent than the

hydroxides of the alkali metals; it separates from water in crystals of the composition $\text{Ba}(\text{OH})_2 \cdot 8\text{H}_2\text{O}$; it is not decomposed even by prolonged ignition. Strontium hydroxide, which also crystallizes with 8 molecules of water, is much less soluble than the barium compound; it is not decomposed by ignition. Calcium hydroxide, $\text{Ca}(\text{OH})_2$, however, requires about 700 parts of cold water to dissolve it, the crystals of strontium hydroxide requiring only 50 parts, and is decomposed into calcium oxide and water by prolonged ignition. When barium hydroxide solution is added to hydrogen dioxide a hydrated barium peroxide, $\text{BaO}_2 \cdot 6\text{H}_2\text{O}$, is precipitated in crystalline scales; the corresponding strontium and calcium compounds, $\text{SrO}_2 \cdot 8\text{H}_2\text{O}$ and $\text{CaO}_2 \cdot 8\text{H}_2\text{O}$, may be prepared in a similar manner, and are converted into the anhydrous oxides by heating to 100°C .

Barium and strontium carbonates are practically insoluble in water, and are not decomposed on ignition; calcium carbonate, CaCO_3 , is only very slightly soluble in water, and is slowly converted into calcium oxide and carbon dioxide on ignition. In this respect lithium carbonate, Li_2CO_3 , closely resembles calcium carbonate, as it is only sparingly soluble in water, and decomposes on ignition; whereas the carbonates of the other alkali metals are very soluble, and are not decomposed by heat.

Calcium sulphate, CaSO_4 , crystallizes with two molecules of water, and is slightly soluble in water; but strontium and barium sulphates form anhydrous crystals, and are practically insoluble in water. Similarly, calcium nitrate crystallizes in deliquescent, very soluble monoclinic prisms of the composition $\text{Ca}(\text{NO}_3)_2 \cdot 4\text{H}_2\text{O}$, and an apparently isomorphous salt of similar composition, but efflorescent, may be obtained by crystallizing strontium nitrate at a low temperature; but from a hot solution strontium nitrate separates in anhydrous octahedra isomorphous with barium nitrate, which crystallizes without water. The chlorides of calcium and strontium are deliquescent crystalline substances, very soluble in water, and also soluble in alcohol; barium chloride is very much less soluble in water, and is insoluble in alcohol, and does not deliquesce. The chlorides of barium, strontium, and calcium furnish perfectly neutral solutions. Barium salts communicate an apple-green colour to flame, strontium salts a brilliant crimson, and calcium salts an orange-red; the spectra of the three elements are comparatively simple.

GLUCINIUM—MAGNESIUM—ZINC—CADMIUM—MERCURY.

Name.	Symbol.	At. wt.	Sp. gr.	At. vol.	F.P. °C.	B.P. °C.	Electric conductivity.
Glucinium	G	9.3	2.1	4.4	25.47 (at 17°)
Magnesium	Mg	23.9	1.74	13.7	29.92 (at 6°)
Zinc	Zn	64.9	7.15	9.1	412	1010	27.72 (at 6°)
Cadmium	Cd	111.6	8.65	12.9	223	860	1.63 (at 23°)
Mercury	Hg	199.8	13.55	14.7	-38.5	357	

Glucinium, or beryllium, obtained by the action of sodium on its chloride, is a white, malleable metal fusible below the melting-point of silver; it does not burn in air or oxygen, but becomes coated with a layer of oxide which seems to protect it from further change. When heated in an atmosphere of chlorine it is converted into the chloride GCl_2 . It does not decompose water even when heated to whiteness. It is easily dissolved by dilute hydrochloric and sulphuric acids; but nitric acid, even when concentrated, has little action on it. It is readily dissolved by a solution of potassium hydroxide.

Glucinium hydroxide, $\text{G}(\text{OH})_2$, separates as a white bulky precipitate on the addition of an alkaline hydroxide to a solution of a glucinium salt; it exhibits pronounced acid properties, dissolving in solutions of the alkalies and even in those of alkaline carbonates. Glucinium oxide, GO , is a light, very bulky, white powder; when strongly heated it volatilizes without fusing. Glucinium chloride, GCl_2 , crystallizes in silky needles; it is very deliquescent, and dissolves in water with a hissing noise and considerable rise of temperature. Glucinium hydroxide readily dissolves in acids, but the ignited oxide slowly; the glucinium salts are mostly soluble, and have a sweet, slightly astringent taste. Basic glucinium salts are obtained with great facility; thus by digestion with the hydroxide, glucinium nitrate, $\text{G}(\text{NO}_3)_2$, is converted into the basic nitrate, $\text{G}_2\text{N}_2\text{O}_6$, and the basic sulphate, G_2SO_4 , may in a similar manner be obtained from the normal sulphate, GSO_4 . Glucinium sulphate, $\text{GSO}_4 \cdot 4\text{H}_2\text{O}$, is extremely soluble in water; it forms a double salt with potassium sulphate of the composition $\text{K}_2(\text{SO}_4)_2 \cdot 2\text{H}_2\text{O}$.

Magnesium, Zinc, Cadmium.—Magnesium is a white, malleable ductile metal about as hard as calc-par; it melts and volatilizes nearly as readily as zinc. It readily decomposes water below its boiling-point, but not in the cold, unless associated with a less positive metal such as copper. It is easily dissolved by dilute acids.

Zinc is a hard, white metal with a shade of blue; when pure it is very malleable, but it is usually brittle owing to the presence of impurities such as lead and iron. Commercial zinc, however, becomes malleable at 100° – 150°C , and may then be rolled; at 210°C it again becomes brittle, and may easily be reduced to powder at that temperature. Zinc decomposes vapour of water at a temperature below dull redness, and readily, even at ordinary temperatures, when it is associated with copper or other less positive metals. The pure metal dissolves very slowly in dilute acids, but ordinary zinc dissolves quickly, because the lead contained in it acts as an electro-negative element. Zinc dissolves in aqueous alkalies with evolution of hydrogen.

Cadmium is a bluish-white metal like zinc; it is soft, though harder and more tenacious than tin, and is very malleable and ductile. When heated to about 80°C it becomes very brittle, and may be powdered with facility. It appears to decompose water at a high temperature, and dissolves when heated with slightly diluted hydrochloric or sulphuric acid, but its best solvent is dilute nitric acid.

Magnesium is usually prepared by heating its chloride with sodium; zinc and cadmium are readily obtained by reducing their oxides with charcoal. Magnesium, zinc, and cadmium are capable of being polished, and then assume a bright metallic lustre; they retain their lustre in dry air, but when exposed to moist air a film of oxide forms on the surface which protects them from further oxidation. Magnesium is the most positive metal of the three, as it precipitates zinc and cadmium from their salts, and zinc is more positive than cadmium. When heated in chlorine, or in the vapour of bromine or of iodine, they burn brilliantly, forming corresponding chlorides, bromides, or iodides, such as MgCl_2 , ZnBr_2 , CdI_2 ; if moistened with water, zinc and cadmium readily combine with the halogens at the ordinary temperature.

They are easily combustible in air or oxygen; the light emitted by burning magnesium is intensely brilliant and very rich in actinic rays; zinc also burns with a brilliant flame. They are thus converted into the oxides MgO , ZnO , CdO ; magnesium and zinc oxides are white, but the latter becomes lemon yellow when heated; cadmium oxide is yellowish brown. These oxides are unalterable in the fire; they dissolve readily in acids, forming corresponding

salts, *e.g.* : $\text{MgO} + \text{H}_2\text{SO}_4 = \text{MgSO}_4 + \text{H}_2\text{O}$. Magnesium oxide, when mixed with water, gradually combines with it, and forms the hydroxide $\text{Mg}(\text{OH})_2$, but no sensible development of heat occurs during the hydration. Cadmium oxide also unites with water.

The hydroxides of magnesium, zinc, and cadmium separate as white amorphous precipitates, insoluble in water, on the addition of alkalis to solutions of the salts of these metals. Magnesium hydroxide alone exhibits a faint alkaline reaction; zinc hydroxide readily dissolves in alkalis; they are all dissolved by solutions of ammonium salts; they are easily resolved by heat into water and the oxide.

Cadmium also furnishes a suboxide, Cd_2O , which is a green powder; on treatment with acids it is resolved into metallic cadmium and the oxide CdO ; in other words, a salt of the oxide CdO is produced, and cadmium remains.

The chlorides of these metals, like glucinum chloride, are volatile deliquescent solids; magnesium and zinc chlorides are extremely soluble in water, and their solutions are strongly acid, but cadmium chloride is less soluble; their dissolution in water is attended with development of heat, thus :—

Their bromides and iodides are also soluble in water. The chlorides of magnesium, zinc, and cadmium form crystalline compounds with the chlorides of many other metals, the tendency to combine with other chlorides being especially marked in the case of cadmium chloride.

Their sulphates are soluble in water, especially those of magnesium and zinc, which are isomorphous; the sulphates of the three metals form isomorphous double salts with potassium sulphate. The composition of their sulphates and double sulphates with potassium is as follows :—

Zinc, like glucinum, manifests a great tendency to form basic sulphates.

The carbonates of magnesium, zinc, and cadmium are white and insoluble in water; they are without difficulty decomposed by heat into the oxide and carbon dioxide.

Glucinum sulphide is soluble in water without decomposition, but is decomposed by dilute acids; magnesium sulphide is converted by water into magnesium hydroxide with evolution of hydrogen sulphide: $\text{MgS} + 2\text{H}_2\text{O} = \text{Mg}(\text{OH})_2 + \text{H}_2\text{S}$; zinc sulphide is insoluble in water, but is dissolved and decomposed by dilute mineral acids; lastly, cadmium sulphide is insoluble in water and dissolves with difficulty even in boiling dilute hydrochloric acid, though it is readily decomposed by concentrated hydrochloric acid even at ordinary temperatures. Cadmium sulphide is a brilliant yellow substance, the remaining sulphides are white.

Mercury.—This element is the only metal that is liquid at common temperatures, with the exception, possibly, of cesium, and the recently discovered element gallium. The latter element, indeed, appears to be closely allied to zinc in properties, but is less positive, and is probably a member of the aluminium group; its specific gravity is 5.95.

Mercury occurs native chiefly in the form of sulphide, from which it is separated either by distillation with slaked lime (calcium hydroxide), or by burning off the sulphur. It is a highly lustrous metal, and in the solid state is malleable. It slowly combines with the halogens at ordinary temperatures, and also with sulphur if triturated with it; it does not tarnish, even in moist air, but slowly absorbs oxygen when heated to about 400°C ., being converted into the

red oxide HgO ; this oxide is decomposed on ignition. Hydrochloric acid, whether cold or hot, is without action on mercury, but it is slowly dissolved by hydriodic acid; concentrated nitric acid dissolves it readily; it is also dissolved by hot concentrated sulphuric acid. It has no action upon water at any temperature. It is capable of uniting with most metals, forming liquid or solid compounds called amalgams; the solid amalgams appear for the most part to be of definite composition, but the two metals are held together by very feeble affinities.

Mercury unites with the halogens, with oxygen, and with sulphur in two proportions, forming the two series distinguished as mercurous and mercuric compounds; thus :—

The compounds of mercury with halogens, and mercury compounds generally, are difficultly soluble, or insoluble, in water. But the compounds with halogens dissolve readily in solutions of the haloid compounds of the alkali metals in consequence of the formation of double salts; the haloid compounds of mercury, in fact, exhibit a more marked tendency than those of any other metal of the group to form double salts with the haloid compounds of other metals, cadmium being most nearly allied to mercury in this respect; they unite also with the haloid acids, forming the compounds HHgCl_2 , HHgBr_2 , and HHgI_2 .

Mercurous chloride or calomel, Hg_2Cl_2 , is a white crystalline solid, insoluble in water; it blackens slowly on exposure to light, and is decomposed by heat into metallic mercury and mercuric chloride, HgCl_2 . Mercuric chloride or corrosive sublimate is also white and crystalline, but soluble in water, it boils without decomposition at 295°C .; the density of its vapour corresponds with the formula HgCl_2 . By the action of ammonia on the chlorides of mercury, one-half the chlorine is removed and displaced by the monad radicle amidogen: $\text{Hg}_2\text{Cl}_2 + 2\text{NH}_3 = \text{Hg}_2\text{Cl}(\text{NH}_2) + \text{NH}_4\text{Cl}$; the lower chloride is thus converted into black mercurous amidochloride, the higher chloride furnishing mercuric amidochloride or white precipitate, $\text{HgCl}(\text{NH}_2)$.

Mercury hydroxides are unknown, the chlorides of mercury being at once converted into corresponding oxides by the action of alkalis; but when mercury is associated with positive hydrocarbon radicles, it forms powerfully basic hydroxides such as $\text{Hg}(\text{C}_2\text{H}_5)\text{OH}$, which is a colourless oil. Mercurous oxide, Hg_2O , is a black substance which by mere exposure to light, or a very gentle heat, is converted into the metal and the red oxide. Mercuric oxide, HgO , when prepared by heating mercury in oxygen, forms red crystalline scales, but it is precipitated as a yellow powder on the addition of an alkali to a solution of mercuric chloride. These two forms of the oxide differ even in their chemical behaviour, and are perhaps polymeric; thus, when the yellow oxide is boiled with a solution of potassium dichromate a basic mercuric chromate, Hg_2CrO_6 , is formed, but the crystallized oxide forms a more basic salt, viz., Hg_2CrO_7 , under similar circumstances. Mercuric oxide is dissolved by acids, forming mercuric salts such as mercuric nitrate, $\text{Hg}(\text{NO}_3)_2$; by digesting solutions of these salts with mercury they are converted into corresponding mercurous salts such as mercurous nitrate $\text{Hg}_2(\text{NO}_3)_2$. But mercuric oxide also exhibits feeble acid properties; thus it forms the compound K_2HgO_2 when dissolved in fused potassium hydroxide. Basic mercuric salts are also very readily produced; mercuric sulphate, HgSO_4 , for example, is decomposed by water into a soluble acid salt and the insoluble basic sulphate Hg_2SO_6 . Mercuric sulphide, HgS , is thrown down as a black

precipitate on passing hydrogen sulphide through solutions of mercuric salts; it is not decomposed by hydrochloric acid; when heated it becomes red. Native cinnabar and vermilion consist of the red modification of mercuric oxide.

No tendency to combine with hydrogen has been observed in the case of the metals of this group, but they have all been obtained in combination with hydrocarbon radicles. Their organo-metallic derivatives correspond in composition to zinc ethyl, $\text{Zn}(\text{C}_2\text{H}_5)_2$, the attempt to convert mercurous chloride into a corresponding organo-metallic compound by the action of zinc ethyl has been unsuccessful, mercury ethyl, $\text{Hg}(\text{C}_2\text{H}_5)_2$, being formed instead and mercury separated; thus:—

It would appear, in fact, that only mercurous compounds can exist in which mercury is associated with negative radicles.

It has been shown that the density of the vapour of each of the metals cadmium and mercury is the half of its atomic weight, in other words, the gaseous molecules of these elements are monatomic (p. 471). As we are not acquainted with the density of any other metal in the state of gas, it is impossible to say whether these metals are peculiar in this respect.

On comparing the properties thus briefly sketched of the elements of this group, the general resemblance will be at once noticed, but it will be remarked also, that, although in respect of many properties the variations are gradational in the same degree as the atomic weights, certain properties are not continuous, but recur periodically. Thus glucinum, zinc, and mercury, the first, third, and fifth terms of the group, have many characteristics in common which are apparently wanting in the case of magnesium and cadmium, the second and fourth terms. This is evidenced especially by certain of their physical properties, by the solubility of their hydroxides in alkalies, by the formation of basic salts, and by the behaviour of their sulphides.

The elements of this group are in many respects closely related to the metals of the previous group, of which they may be regarded as forming a sub-group, the formulae of their compounds being similar in most cases; the general behaviour especially of magnesium and its compounds, it will be evident, is in close accordance with that of calcium and its compounds. But many important distinctions characterize the two groups. Thus the metals of the one group decompose cold water; their oxides are powerfully basic, and readily combine with water; their carbonates are extremely stable; and their sulphates are insoluble or very slightly soluble in water, and do not readily form double salts. The metals of the other group, however, either are without action on water, or decompose it only when heated; their oxides, although basic, exhibit little tendency to combine with water; their carbonates are comparatively unstable; and their sulphates are mostly very soluble in water, and readily form double salts. In the one group the positive character becomes more pronounced as the atomic weight increases, whereas in the other the positive character diminishes with increase of atomic weight.

Glucinum, apparently, is much less closely related to magnesium than is the latter to zinc, and mercury much less closely to cadmium than cadmium to zinc; but zinc and cadmium are more closely related than zinc and magnesium. These conclusions, which result chiefly from the comparison of what may be termed chemical properties, are entirely confirmed by Thomson's thermochemical investigation of the reactions involved in the formation of a number of compounds of the metals of this group, as will be evident from the following tables:—

COPPER—SILVER—GOLD.

Name.	Symbol.	At. wt.	Sp. gr.	At. vol.	Electric conductivity.
Copper	Cu	63.3	8.9	7.1	56.4 at 13° C.
Silver	Ag	107.6	10.5	10.2	100.0 „ 0° C.
Gold	Au	196.2	19.3	10.1	77.0 „ „

These metals may be regarded as forming a sub-group to the metals of the alkalies.

Copper is a very tenacious, ductile, malleable metal, of red colour, more easily fused than gold, but less fusible than silver. It is without action on water at a red heat, and does not oxidize in the air at ordinary temperatures, but when heated to redness it rapidly combines with oxygen forming a black oxide CuO ; when in a finely divided state, it readily unites with chlorine at ordinary temperatures. Moderately diluted nitric acid dissolves copper with great facility, and it is also dissolved by heated concentrated sulphuric acid; hydrochloric acid, even when boiling, has little action on the massive metal, but slowly dissolves the finely divided metal.

Copper forms two chlorides,—cuprous chloride, Cu_2Cl_2 , and cupric chloride, CuCl_2 , but only one iodide Cu_2I_2 . Cuprous chloride is a white crystalline substance insoluble in water, but it dissolves in hydrochloric acid or ammonia, forming colourless solutions. Cupric chloride is readily soluble; it is liver-coloured, but its solution in water is blue; it forms crystalline double salts with the chlorides of the alkali metals. It is converted into cuprous chloride and chlorine at a red heat.

Cupric hydroxide, $\text{Cu}(\text{OH})_2$, separates as a pale blue precipitate on the addition of an alkali to a solution of a cupric salt; in the dry state it is stable at 100° C., but at a slightly higher temperature it is converted into the black oxide. Cupric hydroxide, although insoluble in alkalies,

¹ These numbers refer to a sulphate of the composition $\text{CuSO}_4 + \frac{1}{2}\text{H}_2\text{O}$

is dissolved by ammonia to a deep blue solution; the production of deep blue-coloured liquids on dissolution in ammonia is, in fact, characteristic of copper compounds. Cupric oxide, CuO , dissolves in acids, forming cupric salts, which are white when anhydrous, but furnish green or blue solutions; they are mostly soluble. Cupric sulphate crystallizes with 5 molecules of water, but it forms a double sulphate with potassium sulphate, $\text{CuK}_2(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$, isomorphous with the corresponding zinc and magnesium salts. Basic cupric salts are readily produced by digesting the normal salts with cupric hydroxide.

By igniting cupric oxide with metallic copper it is converted into red cuprous oxide, Cu_2O ; this oxide may also be prepared by heating a solution of a cupric salt with an easily oxidizable substance, such as grape sugar, and an alkali. Most acids decompose cuprous oxide, forming a cupric salt and separating metallic copper; but it is converted into cuprous chloride by hydrochloric acid. A number of cuprous salts exist, but they are extremely unstable, and mostly absorb oxygen readily, becoming converted into cupric salts. Both oxides of copper are easily reduced by ignition with hydrogen or charcoal.

A black hydrated cupric sulphide is precipitated by hydrogen sulphide even from strongly acid solutions of cupric salts.

Cuprous hydride, Cu_2H_2 , is deposited as a yellow precipitate when a solution of cupric sulphate mixed with hypophosphorous acid is heated to about 60°C .; it soon turns brown, and when heated to 70°C . suddenly decomposes, with evolution of hydrogen; hydrochloric acid converts it into cuprous chloride:—

Silver is a white metal, inferior in malleability only to gold among the heavy metals; it is harder than gold, and softer than copper. It is the best-known conductor of heat and electricity. It may be distilled by the aid of the oxy-hydrogen flame. It is not oxidized by ordinary oxygen, and is incapable of decomposing water, but like mercury it is oxidized by ozone. Moderately diluted nitric acid dissolves it readily, and it is dissolved by heated concentrated sulphuric acid; it also resembles copper and mercury in its behaviour with hydrochloric acid, and mercury in its behaviour with hydriodic acid. It unites with the halogens at ordinary temperatures, and, like mercury, readily combines with sulphur, and is precipitated by hydrogen sulphide from strongly acid solutions of its salts as black sulphide, Ag_2S .

Silver forms two chlorides,—argentic chloride, AgCl , which is white, and insoluble in water, but readily soluble in ammonia, and a black argentous chloride, the composition of which is not known with certainty, but is probably Ag_2Cl_2 . Corresponding bromides exist, but only the one iodide, AgI , is known. Argentic chloride becomes violet-coloured on exposure to light, apparently owing to the formation of the lower chloride; the iodide does not alter in appearance, but acquires the property of attracting metallic silver, and hence its employment in photography. The subchloride is not changed by nitric acid, but is converted by ammonia into metallic silver and argentic chloride.

A brown argentous hydroxide, $\text{Ag}(\text{OH})$, is precipitated from solutions of argentic salts on the addition of an alkali; it is slightly soluble in water and its solution is faintly alkaline; it loses water at a temperature above 60°C ., and is converted into argentic oxide, Ag_2O . Argentic oxide is a brown powder; it gives off a certain amount of oxygen, even at 100°C ., and also when exposed to sunshine; it neutralizes the strongest acids, forming argentic salts such as argentic nitrate, AgNO_3 . Argentic sulphate, Ag_2SO_4 , is isomorphous with anhydrous sodium sulphate, and it also

forms an alum, $\text{Ag}_2\text{Al}_2(\text{SO}_4)_4 \cdot 24\text{H}_2\text{O}$, which, however, is extremely unstable.

Silver also forms a suboxide probably of the composition Ag_2O_2 , and a peroxide of which the composition is uncertain, but probably is expressed by the formula Ag_2O_2 . Both are extremely unstable; the former is decomposed by ammonia into metallic silver and argentic oxide, which dissolves, and acids act upon it in a similar manner.

Argentic carbonate is insoluble in water, and decomposes at 200°C . into the oxide and carbon dioxide.

Metallic silver is slowly precipitated from solutions of its salts by hydrogen at ordinary temperatures, so that it is a less positive element than hydrogen.

Gold is a metal of rich yellow colour nearly as soft as lead when in a pure state. It exhibits no tendency to combine directly with oxygen, and is not dissolved by any single acid, except selenic acid, but it readily combines with the halogens, and therefore dissolves in a mixture of nitric and hydrochloric acids, which liberates chlorine (p. 466).

Gold is reduced from its compounds with extreme readiness, but varies in properties according to the nature of the compound from which it is separated; in fact, it appears to exist in several allotropic modifications. Thus, according to Thomsen, when a solution of auric chloride is reduced by sulphurous acid, the gold separates as a light-coloured powder which readily cakes together, but from a solution of auric bromide it separates as an extremely fine dark-coloured powder which exhibits no tendency to agglomerate; a third modification, also finely pulverulent, but lustrous, is obtained by reducing aurous bromide or iodide with sulphurous acid. Thomsen finds that the conversion of the second ($\text{Au}\alpha$) and third ($\text{Au}\beta$) of these modifications into that obtained from auric chloride (Au) would involve development of heat, and of different amounts in the two cases; thus:—

By the action of chlorine, reduced gold is converted into the chloride, Au_2Cl_3 ; this is decomposed by water into aurous chloride, Au_2Cl_2 , and auric chloride, AuCl_3 . Auric chloride is soluble in water, but aurous chloride is insoluble; in contact with water, especially on warming, the latter decomposes into metallic gold and auric chloride. Auric chloride is readily converted into aurous chloride when heated to 185°C . The gold bromides may be obtained in a similar manner, and exhibit similar properties, but are less stable. Aurous and auric iodides, Au_2I_2 and AuI_3 , are both insoluble, and still less stable. The auric compounds combine with the haloid acids, and with the haloid compounds of most other metals, forming crystalline so-called double salts; these double salts, however, may be regarded as salts of the acids formed by the union of the haloid acids with the auric halogen compounds; the double chloride of gold and potassium, for example, $\text{KCl} \cdot \text{AuCl}_3$, as the potassium salt of the acid HAuCl_4 .

On treating aurous chloride with a solution of potassium hydroxide, a dark-green substance is obtained, which is probably the corresponding hydroxide; it decomposes spontaneously into metallic gold and auric hydroxide. Auric hydroxide, $\text{Au}(\text{OH})_3$, is precipitated by alkalis from a solution of auric chloride as a dark-brown powder, which is quickly reduced on exposure to light. A third gold hydroxide, derived from the oxide Au_2O_3 , appears also to exist.

The hydroxides of gold exhibit very feeble basic properties; in fact, the salts formed on dissolving auric hydroxide in nitric and sulphuric acids are so unstable that they have not been isolated. Auric hydroxide, however, possesses marked acid properties, and is dissolved by a solution of potassium hydroxide,—potassium aurate a

crystalline salt of the composition $\text{KAuO}_2, 3\text{H}_2\text{O}$, separating from the solution on concentration. On digesting auric hydroxide with ammonia it is converted into the so-called fulminating gold, which is obtained in the form of a yellowish-brown powder easily exploded by percussion or heat; it is somewhat uncertain what is the composition of this body, but it is not improbable that it is represented

by the formula $\text{Au}(\text{NH}_2)\left\{\begin{array}{l} \text{OH} \\ \text{ONH}_2 \end{array}\right.$.

The distinctions between copper, silver, and gold are obviously very marked; yet they resemble each other in many respects, the relation being especially evident when the cuprous and aurous compounds are compared with the argentic compounds. It is to be noted that their hydroxides and many other of their compounds are acted on by ammonia in a characteristic manner, both silver and gold hydroxides being converted into highly explosive bodies; the nature of the products has not been ascertained with certainty, but apparently they are allied in composition. The ammoniacal derivatives of copper correspond in composition to those formed from nickel, a metal which in many respects is allied to copper.

As in the magnesium group of metals, the positive character diminishes with increase of atomic weight, but to a much greater extent.

Silver is the only element of the group which exhibits marked analogy with the metals of the alkalis,—being connected with them by the isomorphism of its sulphate with that of sodium, by the formation of an alum, by the alkalinity of its hydroxide, and by its colour. Thermo-chemical investigation also indicates a marked analogy between silver and the metals of the alkalis, the sulphates of silver, sodium, and potassium dissolving in water with absorption of heat, whereas nearly as much heat is developed on dissolving copper sulphate as when the equivalent amount of sulphuric acid is added to water, copper sulphate resembling in this respect the sulphates of magnesium and zinc; thus:—

$\text{Ag}_2\text{SO}_4, \text{Aq} =$	$-4,480$	units of heat.
$\text{K}_2\text{SO}_4, \text{Aq} =$	$-6,380$	"
$\text{Na}_2\text{SO}_4, \text{Aq} =$	-60	"
$\text{CuSO}_4, \text{Aq} =$	$16,300$	"
$\text{ZnSO}_4, \text{Aq} =$	$18,500$	"
$\text{MgSO}_4, \text{Aq} =$	$20,300$	"

The existence of double salts such as $\text{CuK}_2(\text{SO}_4)_2, 6\text{H}_2\text{O}$, isomorphous with those derived from the sulphates of magnesium and zinc, and the readiness with which basic salts of copper are formed, are confirmatory of the conclusion that copper is allied to zinc and magnesium.

The results of the thermo-chemical investigation of copper, silver, and gold are of considerable interest, as will be evident from the following tables. To illustrate the application of the values in these tables, it may be pointed out that the stability of the oxides of copper and the instability of silver oxide and of auric hydroxide are explained by the fact that much heat is developed in the formation of the oxides of copper from their elements, whereas the formation of silver oxide would involve but a slight development of heat, and the formation of auric hydroxide would even involve a large expenditure of energy. Then it will be noticed that, in the formation of cuprous iodide, heat is developed to the extent of 32,520 units per molecule, and that the formation of an aqueous solution of cupric iodide would involve the development of only 10,410 units per molecule; hence it follows that the conversion of two molecules of cupric iodide into a molecule of cuprous iodide and a molecule of iodine would be attended by the development of no less than $32,520 - 2 \times 10,410 = 11,700$ units of heat. This explains the fact that a mixture of cuprous iodide and iodine, and not cupric

iodide, is obtained on adding potassium iodide to a solution of cupric sulphate:—

Again, the superior affinity of auric bromide for hydrogen bromide as compared with that of auric chloride for hydrogen chloride is shown by the development of 7700 units of heat in the formation of the compound AuBr_3H , and of only 4530 units in the formation of the corresponding chlorine compound AuCl_3H ; and that the latter is almost completely decomposed and converted into the former on treatment with hydrobromic acid is evidenced by the development of 13,800 units of heat in the reaction, complete decomposition requiring the development of 14,300 units.

THALLIUM—LEAD.

Name.	Symbol.	At. wt.	Sp. gr.	At. vol.	Electric conductivity at 0° C.
Thallium	Tl	203.6	11.8	17.2	9.36
Lead	Pb	206.4	11.4	18.1	8.32

Thallium is a heavy crystalline metal, resembling cadmium in appearance; it is extremely soft, even lead scratching it readily. It melts at 294° C., and boils below a white heat; the liquid metal can hardly be distinguished from mercury. It is reduced from solutions of its salts by zinc, but not by cadmium. It readily dissolves in concentrated nitric acid, and is also dissolved by dilute sulphuric acid, especially if it be in contact with a piece of platinum, but it is only slowly attacked even by boiling hydrochloric acid; it decomposes water at a red heat. It combines with the halogens at ordinary temperatures. When exposed

to the air it oxidizes almost as readily as the more positive alkali metals, chiefly thallous oxide, Tl_2O , being formed; and when heated to redness and plunged into oxygen it burns brilliantly with a pure green light, chiefly thallie oxide, Tl_2O_3 , being produced.

Four chlorides of thallium have been described, viz., $TlCl$ or Tl_2Cl_2 , Tl_2Cl_4 , Tl_3Cl_6 , and $TlCl_3$ or Tl_2Cl_6 ; corresponding bromides, and the two iodides, TlI or Tl_2I_2 , and TlI_3 or Tl_2I_6 , have also been obtained. Thallous chloride, $TlCl$ or Tl_2Cl_2 , separates as a white precipitate scarcely distinguishable at first sight from silver chloride, on the addition of hydrochloric acid to a solution of a thallous salt; but in properties it more nearly resembles lead chloride, $PbCl_2$, being slightly soluble in boiling water, from which it separates again on cooling in crystals, and scarcely more soluble in aqueous ammonia than in water. Thallium sesquichloride, Tl_3Cl_6 , formed by melting thallous chloride in a stream of chlorine, crystallizes in brilliant orange-yellow plates, moderately soluble without decomposition in water slightly acidulated with hydrochloric acid. Thallie chloride, $TlCl_3$ or Tl_2Cl_6 , is formed on dissolving thallie oxide in hydrochloric acid; it crystallizes from hydrochloric acid in colourless prisms of the composition $TlCl_3 \cdot H_2O$ or $Tl_2Cl_6 \cdot 2H_2O$. Little is known of the chloride Tl_2Cl_4 , but the corresponding bromide is obtained on adding thallous bromide to a hot solution of thallie bromide, separating from the hot liquid in yellow shining needles. Thallous bromide is nearly insoluble in water, but thallie bromide is very soluble and deliquescent; the bromide Tl_2Br_4 is decomposed by water into thallous and thallie bromide and the bromide Tl_4Br_6 , which crystallizes in orange-red laminae. This last compound is also decomposed by water, with separation of thallous bromide. Thallous iodide, TlI or Tl_2I_2 , has a brilliant yellow colour, and is almost insoluble in water, and scarcely more soluble in a solution of potassium iodide; when heated it becomes scarlet, but its yellow colour is restored by friction. It is therefore opposite in character to mercuric iodide, HgI_2 , which is scarlet, but becomes yellow when heated, and is readily soluble in potassium iodide solution, although insoluble in water. Thallie iodide is an extremely unstable compound, and, like cupric iodide, readily decomposes into iodine and thallous iodide.

Thallous oxide is almost black in colour; like litharge, PbO , the corresponding lead oxide, it fuses readily, and the fused oxide is absorbed by bone-ash so that a silver thallium alloy may be cupelled like a silver-lead alloy. It dissolves readily in water, forming a colourless, powerfully alkaline solution, greasy to the touch, of thallious hydroxide, $Tl(OH)$ or $Tl_2(OH)_2$. The latter compound may be obtained in pale-yellow prismatic crystals; it is reconverted into the oxide by mere exposure over sulphuric acid in a vacuum at the ordinary temperature. The solution of thallious hydroxide has nearly all the properties characteristic of sodium hydroxide; but it has a slight tendency to absorb oxygen. Thallie hydroxide, $Tl(OH)_3$ or $Tl_2(OH)_6$, separates as a brown gelatinous precipitate on the addition of alkalis to a solution of a thallie salt; by heating to about $260^\circ C$. it is converted into thallie oxide, Tl_2O_3 . This oxide is a dark brown powder fusible with difficulty; it is reduced to the lower oxide at a red heat. It has much less marked basic properties than thallous oxide, but dissolves readily in acids, forming thallie salts; it is insoluble in water. Thallous salts are not precipitated by hydrogen sulphide in presence of strong acids, but the thallium is completely precipitated as a brown sulphide from solutions of the salts of weak acids, such as thallious acetate, and by alkaline sulphides.

Thallious hydroxide readily absorbs carbon dioxide, forming thallious carbonate, Tl_2CO_3 . This salt crystallizes in prisms, and is soluble in about four times its weight of

boiling water, forming an alkaline solution; it is fusible, but decomposes when heated to dull redness. Thallous sulphate, Tl_2SO_4 , is isomorphous with potassium sulphate; it also forms an alum, $Tl_2Al_2(SO_4)_4 \cdot 24H_2O$, and double salts such as $Tl_2Mg(SO_4)_2 \cdot 6H_2O$, isomorphous with the corresponding potassium salts. A large number of thallous salts, in fact, are isomorphous with the corresponding sodium, potassium, and ammonium salts. Thallie sulphate, $Tl_2(SO_4)_3 \cdot 7H_2O$, is decomposed even by cold water; it forms an anhydrous double sulphate with potassium sulphate quite different from the alums in composition, viz., $Tl_2(SO_4)_3 \cdot 2K_2SO_4$.

Lead is a bluish-white, extremely soft metal; it fuses at $325^\circ C$. It is readily dissolved by nitric acid, and is slowly acted on when boiled with hydrochloric or dilute sulphuric acid, hydrogen being evolved. Although it tarnishes in the air, the oxidation is only superficial, but it readily absorbs oxygen when heated. Its oxides are very easily reduced.

Only one stable chloride of lead, $PbCl_2$, is known; when, however, the oxides Pb_2O_3 and PbO_2 are dissolved in hydrochloric acid at a low temperature, solutions are formed which apparently contain the corresponding chlorides Pb_2Cl_4 and $PbCl_4$, as the oxides may be reprecipitated by alkalis, but the slightest heat causes chlorine to be evolved. Lead chloride is difficultly soluble in water, from which it crystallizes in delicate white needles. Lead iodide, PbI_2 , crystallizes in brilliant yellow plates sparingly soluble in water.

Lead forms a suboxide, Pb_2O , a monoxide, PbO , a dioxide or peroxide, PbO_2 , and a fourth oxide, Pb_3O_4 , which may be regarded as a compound of the monoxide and dioxide. The suboxide is black; like the corresponding oxides of mercury and silver, it furnishes the metal and a salt derived from the monoxide on treatment with acids. The monoxide, PbO , ordinarily known as litharge, is prepared on the large scale by the oxidation of lead in air; the pure oxide has a lemon-yellow colour, and is insoluble in water; it fuses at a heat below redness. The corresponding hydroxide, $Pb(OH)_2$, is obtained on adding ammonia to a solution of a lead salt such as lead nitrate, $Pb(NO_3)_2$, as a white amorphous precipitate, which absorbs carbon dioxide on exposure to air; it is converted into the oxide when heated above $100^\circ C$. The oxide and hydroxide are readily acted on by acids, and form stable salts; but they are also soluble in alkalis. Lead nitrate is easily soluble, but lead sulphate and carbonate are insoluble in water; they may be obtained in crystals isomorphous with those of the corresponding barium salts. The carbonate is readily decomposed when heated, and on heating the sulphate with lead sulphide metallic lead is obtained: $PbSO_4 + PbS = 2Pb + 2SO_2$.

Lead sesquioxide, Pb_2O_3 , is little known; it has a brown colour, and is converted into the monoxide and oxygen when heated. Lead dioxide, PbO_2 , also has a brown colour; it may be obtained by passing chlorine into water in which lead oxide is suspended. It unites directly with sulphur dioxide, forming lead sulphate, sufficient heat being developed to cause the mass to glow; it is converted into the monoxide when heated; it is insoluble in most acids, but is dissolved by acetic acid, and apparently converted into a corresponding acetate; by fusing it with potassium hydroxide, potassium plumbate is produced, which may be obtained in crystals of the composition $K_2PbO_3 \cdot 3H_2O$.

By carefully heating lead monoxide to low redness in air it is converted into the red oxide or minium, the most usual composition of which is represented by the formula Pb_3O_4 . On treating this oxide with acids—nitric acid, for example—it furnishes lead nitrate and lead dioxide.

Lead is precipitated by hydrogen sulphide, as a black sulphide, even from strongly acid solutions of its salts.

Although no stable chloride of lead exists containing more than two atoms of chlorine, a stable tetraethyl derivative

$\text{Pb}(\text{C}_2\text{H}_5)_4$, the existence of which affords conclusive evidence that lead may function as a tetrad element, is obtained by the action of zinc ethyl on the chloride PbCl_2 ($1\text{Pb}_2\text{Cl}_4$). The hydroxide, $\text{Pb}(\text{C}_2\text{H}_5)_2\text{OH}$, is powerfully basic.

Compounds of thallium with hydrocarbon radicles only have not yet been obtained; a thallium diethylechloride, $\text{Tl}(\text{C}_2\text{H}_5)_2\text{Cl}$, is known, however. It is a crystalline body of remarkable stability, and is readily converted into the hydroxide, $\text{Tl}(\text{C}_2\text{H}_5)_2\text{OH}$, which is also crystalline and very soluble in water; the solution is strongly alkaline, nevertheless the hydroxide does not exhibit the slightest tendency to attract carbon dioxide, although it readily forms salts with other acids.

The relation of thallium to lead will be sufficiently evident from the above sketch of the properties of some of the more important compounds of the two elements; it will be noticed also that thallium has strong points of resemblance with the metals of the alkalies, and that it is in some respects related to mercury. Its relation to the alkali metals is especially indicated by the extreme readiness with which it is oxidized, by the properties of thallous hydroxide, and by the isomorphism of many thallous compounds with the corresponding potassium and sodium compounds. Thermochemical investigation entirely confirms these conclusions, as will be evident from the following tables, the heat of neutralization of thallium hydroxide being equal to that of the hydroxides of potassium and sodium, but the affinity of thallium for oxygen being only about equal to that of mercury and copper, and somewhat less than that of lead. The heat of neutralization of thallic hydroxide exceeds that of aluminic hydroxide.

BORON—ALUMINIUM—INDIUM.

Name.	Symbol	At. wt.	Sp. gr.	At. vol.	Electric conductivity.
Boron	B	11	2.6	4.2	33.76 at 20° C.
Aluminium	Al	27.3	2.6	10.5	
Indium	In	113.4	7.4	15.3	

The first of these elements has already been described. Aluminium is related not only to boron but also to silicon among the non-metals, and to magnesium among the metals. Its oxide is one of the most stable known, and, like silicon and boron oxides, cannot be reduced by charcoal alone. The metal is usually obtained by heating the double chloride of sodium and aluminium, $2\text{NaCl}.\text{Al}_2\text{Cl}_6$, with sodium. Aluminium is a white malleable metal, nearly resembling zinc in colour and hardness; it fuses at a lower temperature than silver, but does not volatilize. It is rapidly dissolved by hydrochloric acid, but only slowly acted on by heated nitric and sulphuric acids; it is readily dissolved by solutions of the alkalies. In a finely-divided state it appears to decompose water almost as easily as magnesium, but when in mass, even if heated to full redness in steam, it decomposes water but slowly, owing to the formation of a coating of oxide on its surface which protects the metal; on this account also it may be heated intensely in air without undergoing more than a superficial oxidation, but in the form of powder it burns brightly when heated to redness in air or oxygen. Aluminium takes fire when heated in chlorine gas, and is converted into the chloride, which is also produced on passing chlorine over an ignited mixture of alumina and charcoal.

Aluminium forms only one chloride, the density of which in the state of vapour corresponds with the formula Al_2Cl_6 ; it also forms only a single oxide, Al_2O_3 . Aluminium chloride is a colourless, crystalline, volatile substance; it is deliquescent and dissolves readily in water, much heat being developed, forming a strongly acid solution. Aluminium hydroxide, $\text{Al}_2(\text{OH})_6$, separates as an almost colourless gelatinous precipitate on the addition of alkalies to a solution of an aluminium salt; it is readily soluble in acids, forming salts such as aluminium sulphate, $\text{Al}_2(\text{SO}_4)_3$. Aluminium sulphate is extremely soluble in water; it is very readily converted into basic salts; it combines with the sulphates of the alkali metals forming characteristic double salts—the so-called alums.

Aluminium hydroxide also possesses marked acid properties, being soluble in alkalies, and furnishing salts such as sodium aluminate, $\text{Na}_3\text{Al}_2\text{O}_6$. On ignition alumi-

niun hydroxide is converted into aluminium oxide or alumina, Al_2O_3 ; if it has been exposed only to a moderate red heat the alumina is a soft, white, light powder like magnesium oxide, and is soluble in acids; but after strong ignition it becomes very hard and insoluble, or difficultly soluble, in acids. Alumina occurs native as corundum in crystals isomorphous with the corresponding oxides of chromium and iron; in the crystalline state it is the hardest substance known next to the diamond, and insoluble in all acids, but like silica it is dissolved on fusion with alkalis.

The only reactions which, in the case of aluminium, have been submitted to thermochemical investigation are—

Reaction.	Units of heat developed.
Al_2, Cl_2	321,870
$\text{Al}_2\text{Cl}_6, \text{Aq}$	153,690
$\text{Al}_2, 6\text{HClAq}$	239,640
$\text{Al}_2, \text{O}_3, 3\text{H}_2\text{O}$	388,800
$\text{Al}_2, \text{O}_3, \text{H}_2$	593,880
$\text{Al}_2(\text{OH})_6, 6\text{HClAq}$	55,920
$\text{Al}_2(\text{OH})_6, 3\text{SO}_3\text{Aq}$	62,970

The resemblance of aluminium to boron, silicon, and magnesium is most evident when the oxides and chlorides are compared. Thus, their oxides are all bodies of great stability, and, excepting magnesium oxide, possess marked acid properties; and their chlorides behave similarly when added to water, boron and silicon chlorides being entirely decomposed, and aluminium and magnesium chlorides at least partially, the reaction in each case being attended by the development of a very considerable amount of heat; thus, according as quantities are taken which are as the molecular weights of the chlorides, or which contain the same amount of chlorine, we have—

$\text{SiCl}_4, \text{Aq} = 81,640$	$\frac{1}{3} \text{SiCl}_4, \text{Aq} = 61,230$
$\text{BCl}_3, \text{Aq} = 79,200$	$\text{BCl}_3, \text{Aq} = 79,200$
$\text{Al}_2\text{Cl}_6, \text{Aq} = 153,690$	$\frac{1}{3} \text{Al}_2\text{Cl}_6, \text{Aq} = 76,845$
$\text{MgCl}_2, \text{Aq} = 35,920$	$1\frac{1}{2} \text{MgCl}_2, \text{Aq} = 53,780$

It may be remarked also that magnesium and aluminium both form very soluble sulphates, which readily combine with other sulphates.

Indium is easily reduced from its oxide by hydrogen, and is precipitated from solutions of its salts by cadmium and zinc. It is an extremely rare metal, and occurs always associated with zinc. It is a soft, ductile, white metal, destitute of crystalline structure, much resembling lead in appearance. It rapidly dissolves in concentrated hydrochloric acid, slowly in dilute nitric and sulphuric acids. It melts at 176°C ., but is much less volatile than cadmium, and may be melted in the air without oxidizing; at a bright red heat it burns with a violet flame forming a yellow oxide, In_2O_3 .

Indium chloride, In_2Cl_6 , sublimes without fusion at an incipient white heat, condensing in soft white laminae. Indium oxide, In_2O_3 , is not volatile even at a white heat; it is readily soluble in acids. It is stated that by heating in a stream of hydrogen the oxides In_7O_9 , In_4O_5 , and InO_2 are in succession formed from it, but their existence as definite compounds has not been satisfactorily established. Indium hydroxide separates as a white gelatinous precipitate on the addition of ammonia to cold solutions of indic salts; it is soluble in alkalis, and on ignition is converted into the oxide In_2O_3 . Indium sulphate forms with ammonium sulphate a double sulphate $\text{In}_2(\text{NH}_4)_2(\text{SO}_4)_4 \cdot 24\text{H}_2\text{O}$, isomorphous with the alums; when heated only to 36°C ., however, this salt is converted into one containing only 4 molecules of water of crystallization.

On passing hydrogen sulphide into solutions of indium a yellow precipitate is obtained, which is decomposed by

hydrochloric acid; no precipitate is produced when aluminium salts are similarly treated, aluminium sulphide being at once decomposed by water and converted into the hydroxide.

CHROMIUM—MANGANESE—IRON—COBALT—NICKEL.

Name.	Symbol.	At. wt.	Sp. gr.	At. vol.	Electrical conductivity.
Chromium	Cr	52.4	6.8	7.7	
Manganese	Mn	54.8	8.0	6.7	
Iron	Fe	55.9	7.8	7.1	16.81 at 0°C .
Cobalt	Co	58.6	8.9	6.5	17.22
Nickel	Ni	58.6	8.2	7.1	13.11

The general resemblance between these metals is very great, but each exhibits properties which serve to distinguish it readily from the others. They are also related to many other elements; thus, chromium and iron are closely allied to aluminium, and chromium is also allied to sulphur and its congeners; manganese manifests some analogy with the halogens; nickel has properties in common with copper; and iron, cobalt, and nickel are closely related to the so-called platinum metals.

The oxides of chromium and manganese are reduced by charcoal only at a white heat; the oxides of the remaining metals are easily reduced on ignition with hydrogen or carbon.

The properties of chromium appear to differ considerably according to the manner in which it is prepared. Thus, by heating its chloride with potassium it is obtained as a dark grey powder, which oxidizes readily, taking fire in the air at a heat below redness, and dissolving in dilute sulphuric and hydrochloric acids. By heating its chloride with sodium, however, it is obtained in hard, shining crystals, insoluble in all acids. The metal prepared by reducing the oxide with charcoal is shining, has a steel-grey colour, and is hard enough to scratch glass.

Manganese is a soft, brittle, greyish-white metal, which oxidizes quickly on exposure to the air, decomposes water slowly at ordinary temperatures, and dissolves easily in acids; it is feebly magnetic.

The properties of iron are too well known to need description. It dissolves readily in acids, and decomposes water rapidly at a red heat, it does not alter in dry air, but rapidly oxidizes in moist air; especially in presence of carbonic acid.

Cobalt has a steel-grey colour; nickel is silver-white. Both are hard, ductile, malleable metals, of great tenacity, somewhat more fusible than iron; they decompose water at a red heat, and like iron dissolve without difficulty in acids. They are not altered by the combined action of air and water at ordinary temperatures, but if previously heated burn in oxygen like iron. Nickel appears to be less oxidizable than cobalt. They are both magnetic metals.

Each of these metals forms several oxides; and hydroxides and chlorides, or fluorides, corresponding to most of their oxides are known, as will be evident from the following list:—

Oxides.				
	Cr_2O_3	Cr_2O_3	MnO_2	CrO_2
Mn_2O_2	Mn_2O_4	Mn_2O_3
Fe_2O_2	Fe_2O_4	Fe_2O_3
Co_2O_2	Co_2O_4	Co_2O_3
Ni_2O_2	...	Ni_2O_3
Hydroxides.				
$\text{Cr}_2(\text{OH})_4$	$\text{Cr}_2(\text{OH})_6$	$\text{Cr}_2(\text{OH})_6$

$\text{Fe}_2(\text{OH})_4$	$\text{Fe}_2(\text{OH})_6$	$\text{Fe}_2(\text{OH})_6$		
$\text{Co}_2(\text{OH})_4$	$\text{Co}_2(\text{OH})_6$	$\text{Co}_2(\text{OH})_6$		
$\text{Ni}_2(\text{OH})_4$	$\text{Ni}_2(\text{OH})_6$	$\text{Ni}_2(\text{OH})_6$		

Chlorides.

Cr_2Cl_4	Cr_2Cl_6		CrF_6
Mn_2Cl_4	Mn_2Cl_6	MnCl_4	MnF_6
Fe_2Cl_4	Fe_2Cl_6
Co_2Cl_4	Co_2Cl_6
Ni_2Cl_4

Their chlorides, and, in fact, their halogen compounds generally, are all easily soluble in water, with the exception of sublimed chromic chloride, Cr_2Cl_6 , which is insoluble in cold, and is only slowly dissolved by boiling water; but if the cold solution contains a minute quantity of chromous chloride, Cr_2Cl_4 , the chromic chloride dissolves immediately with development of heat, forming a green solution identical with that produced by dissolving chromic hydroxide in hydrochloric acid; this effect is, perhaps, due to the formation in the first instance of an intermediate chloride, or combination of the two chlorides, which is decomposable by water. The chlorides which correspond in composition to ferrous chloride, Fe_2Cl_4 , are all perfectly stable, and volatilize without decomposition; chromic and ferric chlorides are also highly stable bodies, but the remaining chlorides are exceedingly unstable. Chromium hexafluoride, CrF_6 , is a very volatile blood-red liquid which is decomposed by water.

Their oxides, with the exception of chromium trioxide or chromic anhydride, CrO_3 , and hydroxides are all insoluble in water, but readily dissolve in acids. Chromic oxide, Cr_2O_3 , is green, and chromium trioxide has a magnificent scarlet colour. Ferric oxide, Fe_2O_3 , has a reddish-brown colour; the oxides of manganese are brownish black; and the oxides of nickel and cobalt are all intensely black like cupric oxide. Chromic and ferric oxides form crystals isomorphous with those of alumina oxide, Al_2O_3 .

The affinity of chromium to oxygen is so great that chromous oxide, Cr_2O_2 , is apparently incapable of existing, and it is difficult to obtain ferrous oxide, Fe_2O_2 , on account of the readiness with which it is oxidized to ferric oxide, Fe_2O_3 . Ferric oxide, like chromic oxide, Cr_2O_3 , is a body of great stability, but unlike the latter it is converted into a lower oxide, ferrous oxide, Fe_2O_2 , on ignition. The most stable oxide of manganese is the corresponding oxide, Mn_2O_4 ; but manganous oxide, Mn_2O_2 , is less readily oxidized than ferrous oxide, and manganic oxide is less stable than ferric oxide; manganese is the only metal of the iron group which forms a dioxide, or, as it is usually termed, a peroxide. Cobaltous oxide, Co_2O_2 , absorbs oxygen when heated to dull redness in air, and is converted into the oxide Co_3O_4 , but when more strongly heated this oxide is reconverted into cobaltous oxide, which is also obtained on igniting cobaltic oxide, Co_2O_3 . Nickelous oxide, Ni_2O_2 , exhibits no tendency to absorb oxygen, and the higher oxide is very readily decomposed by heat. From this it will be evident that the affinity to oxygen diminishes rapidly from chromium to nickel.

Similar differences are noticeable between their hydroxides. Thus, the tendency of chromous hydroxide, $\text{Cr}_2(\text{OH})_4$, to become converted into chromic hydroxide, $\text{Cr}_2(\text{OH})_6$, is so great that it decomposes water even at ordinary temperatures with evolution of hydrogen: $\text{Cr}_2(\text{OH})_4 + 2\text{H}_2\text{O} = \text{Cr}_2(\text{OH})_6 + \text{H}_2$. Ferrous hydroxide does not decompose water in this manner, but in presence of both air and water it is quickly converted into ferric hydroxide: $2\text{Fe}_2(\text{OH})_4 + 4\text{H}_2\text{O} + \text{O}_2 = 2\text{Fe}_2(\text{OH})_6 + 2\text{H}_2$; manganous hydroxide behaves similarly, but oxidizes much less rapidly; cobaltous hydroxide manifests but little tendency to form the higher hydroxide, and nickelous hydroxide is unaffected, when placed in contact with air and water. The two last named hydroxides, however, may be converted into the higher hydroxides by treatment with a solution of sodium hypochlorite.

Their hydroxides are without difficulty converted into the corresponding oxides, giving off water when very gently heated; the behaviour of chromous hydroxide is peculiar, as, when ignited, it is converted into chromic oxide with evolution of hydrogen: $\text{Cr}_2(\text{OH})_4 = \text{Cr}_2\text{O}_3 + \text{H}_2 + \text{H}_2\text{O}$. Many hydroxides are known intermediate in composition between the oxides and the highest hydroxides,—such, for example, as are represented by the formulae $\text{Fe}_2\text{O}(\text{OH})_4$ and $\text{Fe}_3\text{O}_2(\text{OH})_2$, which obviously are intermediate in composition between ferric oxide, Fe_2O_3 , and ferric hydroxide, $\text{Fe}_2(\text{OH})_6$.

With the exception of chromium trioxide, the oxides and hydroxides of the metals now under consideration all exhibit marked basic properties; but chromic hydroxide, like aluminic hydroxide, also has feeble acid properties, dissolving in solutions of the alkalis; and cobaltous and nickelous hydroxides, like cupric hydroxide, readily dissolve in ammonia, the solution of the former being brownish-red, and that of the latter blue. The oxides and hydroxides which correspond in composition with ferrous oxide and hydroxide furnish stable salts such as ferrous sulphate, $\text{Fe}_2(\text{SO}_4)_2$. The chromous salts, however, are but little known; they form either red or blue solutions, which absorb oxygen with avidity, and dissolve nitric oxide gas, forming dark brown solutions. The ferrous salts form pale green solutions, which slowly absorb oxygen, and readily dissolve nitric oxide (p. 513). The manganous salts are of a pale pink colour, and their solutions are scarcely altered in contact with oxygen. Solutions of cobaltous salts have a rose-red colour, unless they are very concentrated or mixed with a strong acid, in which case they are blue. Nickelous salts are green. The solutions of cobaltous and nickelous salts are permanent in air.

A second series of chromium and iron salts corresponding to the oxides Cr_2O_3 and Fe_2O_3 are readily obtained, as they are of great stability. Solutions of chromic salts are green or violet; solutions of ferric salts are yellow. Chromic salts such as chromic sulphate, $\text{Cr}_2(\text{SO}_4)_3$, for example, are reduced to chromous salts by the action of the nascent hydrogen produced when zinc is immersed in their solutions, but they cannot be thus reduced by the aid of iron; ferric salts, however, are readily reduced to ferrous salts even by feeble reducing agents such as hydrogen sulphide. Manganic and cobaltic salts corresponding to the chromic and ferric salts may be obtained, but they are extremely unstable, and nickelic salts appear to be incapable of existing, so that, on treating the higher oxides and hydroxides of manganese, &c., with acids, salts derived from manganous oxide and its congeners are usually obtained. Thus, nickelic oxide, Ni_2O_3 , is converted by the action of sulphuric acid into nickelous sulphate, with evolution of oxygen; similarly, when manganic oxide, Mn_2O_3 , manganic peroxide, MnO_2 , or cobaltic oxide, Co_2O_3 , is carefully dissolved in hydrochloric acid, solutions are obtained which apparently contain the corresponding chlorides, Mn_2Cl_6 , MnCl_4 , and Co_2Cl_6 , but these rapidly decompose with evolution of chlorine, leaving manganous chloride, Mn_2Cl_4 , or cobaltous chloride Co_2Cl_4 . The oxides which correspond in composition to ferrous oxide, Fe_2O_2 , behave with acids as if mixtures of the two oxides. Salts corresponding to chromium trioxide are not obtainable, for on treatment with sulphuric acid it is converted into chromic sulphate, with evolution of oxygen; and by the action of hydrochloric acid it is converted into chromic chloride, with evolution of chlorine. Like all feebly positive metals, the metals of the iron group form numerous basic salts, iron and chromium being especially characterized by the formation of basic chromic and ferric salts; a remarkable series of ferric and chromic "mixed salts," such, for example, as ferric tetraceto-dinitrate, $\text{Fe}_3(\text{NO}_3)_2(\text{C}_2\text{H}_3\text{O}_2)_4$, and chromic pentacetate, $\text{Cr}_2(\text{NO}_3)_2(\text{C}_2\text{H}_3\text{O}_2)_4$, and chromic pentacetate, $\text{Cr}_2(\text{NO}_3)_2(\text{C}_2\text{H}_3\text{O}_2)_4$.

$\text{Cr}_2(\text{NO}_3)(\text{C}_2\text{H}_3\text{O}_2)_5$, have been obtained by dissolving the hydroxides in mixtures of two acids in various proportions. Like aluminic sulphate, chromic, ferric, and manganic sulphates form double salts with the sulphates of the alkali metals, which correspond both in composition and crystalline form with the alums. The chrome alums are almost as stable as the true alums, but the iron alums are much less stable, and the manganese alums are so unstable that water decomposes them into their component salts. Ferrous, manganous, cobaltous, and nickelous sulphates form double sulphates with the sulphates of the alkali metals, corresponding in composition and isomorphous with double sulphates such as $\text{K}_2\text{Zn}(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$ and $\text{K}_2\text{Cu}(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$.

The relation of chromium to sulphur and the allied elements is indicated by the existence of the trioxide CrO_3 ; this oxide, however, is not merely analogous in composition to sulphuric anhydride, but also resembles it in properties. Thus, it dissolves readily in water, forming a strongly acid, yellow solution of chromic acid, H_2CrO_4 ; and the salts of this acid are not only analogous in composition to the corresponding sulphates, but are also isomorphous with them, and are similar to them in many respects, the chromates of metals which form insoluble or difficultly soluble sulphates being as a rule also insoluble or difficultly soluble. But although the chromates are stable salts, chromic acid is not known except in solution, chromic anhydride, CrO_3 , being obtained when the solution is evaporated; moreover, chromic acid very readily parts with oxygen, and on this account is a most valuable oxidizing agent. Acid salts of chromic acid corresponding to the acid sulphates apparently cannot exist, for when a solution of a chromate is rendered acid the colour changes from pale yellow to orange-yellow, the chromate being converted into an anhydrochromate or dichromate, which is formed from two molecules of the acid chromate by the withdrawal of the elements of a molecule of water; thus—

The anhydrochromates are mostly orange-red, the corresponding chromates being yellow; they are very stable, and unlike the anhydrosulphates (p. 507), to which they correspond in composition, dissolve in water unchanged.

The relation of chromium to sulphur is also indicated by the existence of an oxychloride, CrO_2Cl_2 , corresponding to sulphuric chloride (p. 505), SO_2Cl_2 ; it is a blood-red coloured liquid, which is violently decomposed by water, and boils at 118°C . The determination of the vapour density of this compound shows that it is correctly represented by the formula CrO_2Cl_2 .

On fusing an oxide of manganese with potassium nitrate, a deep green-coloured mass is formed, from which potassium manganate, K_2MnO_4 , may be separated in crystals isomorphous with potassium sulphate. A concentrated solution of this salt is decomposed merely by dilution, and the solution cannot be boiled; on adding an acid the colour changes from green to purple-red, the manganate being converted into permanganate:—

The permanganates are much more stable than the manganates, and their solutions may be boiled without their decomposing; but they readily part with oxygen, and are therefore most powerful oxidizing agents.

As the manganates and sulphates are isomorphous it is probable that the two classes of compounds are analogous in constitution; and from the manner in which the permangan-

ates are formed from the manganates it is probable that the former contain at least two atoms of manganese in the molecule, and that potassium permanganate, for example, is represented by the formula $\text{O.MnO}_2(\text{OK})$. But potassium permanganate is isomorphous with potassium perchlorate and periodate; it therefore appears probable that, as already pointed out (p. 497), the formula $\text{K}_2\text{Cl}_2\text{O}_8$ for the former salt is preferable to the simpler formula KClO_4 , by which it is usually represented. The isomorphism of potassium permanganate with potassium perchlorate and periodate is, however, chiefly of interest as an indication that manganese is related to the halogens.

Iron is also capable of yielding a compound analogous to potassium manganate, but much less stable, termed potassium ferrate, K_2FeO_4 ; it is produced by fusing an oxide of iron with nitre. The solution has a cherry-red colour, and on the addition of acids is at once decomposed with evolution of oxygen. The most characteristic compounds of iron, however, are the so-called ferrocyanides and ferrieyanides. Potassium ferrocyanide, $\text{K}_4\text{Fe}_2(\text{CN})_{12}$, is produced on adding potassium cyanide to a solution of a ferrous salt in sufficient amount to redissolve the precipitate which at first forms; it crystallizes from the concentrated solution in beautiful yellow plates. The tendency to form this salt is so great that metallic iron is rapidly dissolved when heated with an aqueous solution of potassium cyanide:—

Not only is the presence of iron in this compound not discoverable by the ordinary tests, but on treatment with hydrochloric acid it furnishes hydroferrocyanic acid, $\text{H}_8\text{Fe}_2(\text{CN})_{12}$, and is not, like most double cyanides, decomposed with evolution of hydrocyanic acid. Potassium ferrieyanide, $\text{K}_3\text{Fe}_2(\text{CN})_{12}$, is produced by the action of chlorine on the ferrocyanide: $\text{K}_4\text{Fe}_2(\text{CN})_{12} + \text{Cl}_2 = \text{K}_3\text{Fe}_2(\text{CN})_{12} + 2\text{KCl}$; it crystallizes in red prisms, and like the ferrocyanide is an extremely stable compound. Other ferro- and ferri-cyanides may be prepared from the potassium compounds by double decomposition.

Cobalticyanides, such as $\text{K}_3\text{Co}_2(\text{CN})_{12}$, isomorphous with the ferrieyanides, are readily obtained, and are equally stable; but the cobaltocyanides are very unstable. Chromicyanides and manganocyanides, isomorphous with the corresponding iron compounds are also known, but they are much less stable than the latter. Nickel does not furnish compounds of this kind, but like copper forms double cyanides, such as $\text{Ni}(\text{CN})_2$, 2KCN , which are readily decomposed by acids with evolution of hydrocyanic acid.

Nickel, although of the same atomic weight as cobalt, it will be manifest, is possessed of very different properties, being in many respects much more nearly related to copper than to cobalt, iron, &c.; it is noteworthy that nickel and copper are the only metals whose compounds form blue solutions with ammonia. The relation of chromium, iron, manganese, and cobalt to one another, and of the first two especially to aluminium, will be sufficiently evident without further remark; the relation of iron, cobalt, and nickel to the platinum metals will be referred to later on.

Manganese and iron are the only elements of this group which have been submitted to thermochemical investigation. Many of the results are of considerable interest; thus, it will be noticed, on reference to the following tables, that much more heat is developed in the formation of manganous chloride, MnCl_2 , or Mn_2Cl_4 , than in that of the corresponding chloride of iron; this is of interest in connection with and may perhaps serve to explain, the great instability of the higher chlorides of manganese.

The only two compounds of the metals of the iron group of which the vapour density has been determined are ferric chloride and chromium oxychloride; the density of the former corresponds to the formula Fe₂Cl₃, and that of the latter to the formula CrO₂Cl₂. Hence the composition of ferric chloride is similar to that of aluminic chloride, the density of which corresponds to the formula Al₂Cl₃, and it is therefore probable that chromic chloride, which is in all respects analogous to aluminic and ferric chlorides, is similarly constituted, and that its formula is Cr₂Cl₃.

The majority of the formulæ employed to represent chemical compounds which cannot be converted into gas are merely the simplest expressions of their composition in terms of the atomic weights of their constituent elements. Thus it is usual to express the composition of the lower chlorides of chromium, iron, manganese, &c., by the simple formulæ CrCl₂, MnCl₂, FeCl₂, and the corresponding oxides by the similar formulæ CrO, MnO, FeO; there are reasons, however, which lead us to suppose that in many cases the less simple formulæ, such as Cr₂Cl₃, Cr₂O₃, are to be preferred, and that the lower chlorides and oxides of iron, &c., like the higher chlorides and oxides, contain at least two atoms of the metal in the molecule. For example, the lower chlorides of chromium and iron are readily converted into the higher chlorides by the action of chlorine; now if the formula of ferrous chloride is FeCl₂, that of ferric chloride being Fe₂Cl₃, the conversion of the former into the latter by the action of chlorine involves the extremely improbable assumption that a molecule of the ferric compound is formed from two molecules of the ferrous compound:—

Chlorine is not known ever to produce an effect of this kind, that is to say, directly to cause the formation of a more complex from a less complex molecule; but its action is frequently to produce an effect the very reverse of this, many instances of simplification of the molecule by the action of chlorine being known. By adopting the formula Fe₂Cl₃ for ferrous chloride a natural interpretation of its conversion into ferric chloride is at once possible, however:—

Corresponding formulæ may be assigned to the lower chlorides of chromium, manganese, cobalt, and nickel, on account of their resemblance to ferrous chloride; and from the general resemblance which the nickel compounds bear to the cupric compounds it appears probable that, if nickel chloride has the formula Ni₂Cl₃, cupric chloride has the formula Cu₂Cl₃.

The argument may be extended much further, and from the more or less perfect resemblance of silver chloride to cuprous chloride, mercurous chloride, and other chlorides which certainly contain at least two atoms of chlorine in their molecules, we may infer that the formula Ag₂Cl₃ is probably a more correct expression than that commonly employed. The existence of a subchloride and a suboxide of silver indicates that silver is not uniformly a monad element, and if we regard copper, silver, and gold as triad elements (although the last mentioned is undoubtedly capable of assuming pentad functions) we may represent their lower chlorides by similar formulæ, and thus, in a measure, account for the similarity in their properties:—

But it has been pointed out that certain of the silver compounds are isomorphous with the corresponding sodium and potassium compounds, and as there is no reason to suppose that the argentic compounds generally are not of similar constitution to argentic chloride, the conclusion that there are two atoms of silver in the molecule of argentic chloride would appear to necessitate the assumption that the compounds of the alkali metals also contain at least two atoms of the metal in their molecules;—that the formula of sodium nitrate, for example, is Na₂(NO₃)₂, and not NaNO₃. The existence of a compound of sodium ethyl with zinc ethyl, NaZn(C₂H₅)₃, from which the former cannot even be separated, appears to show that sodium does not invariably function as a monad.

Speculations of this kind are extremely hazardous, but, as no method is known enabling us to ascertain the molecular composition of compounds which cannot be volatilized, they possess a certain interest and, moreover, point to the necessity of investigation in this direction.

RUTHENIUM—RHODIUM—PALLADIUM—OSMIUM—IRIDIUM—PLATINUM.

Name.	Symbol.	At. wt.	Sp. gr.	At. vol.
Ruthenium	Ru	103.5	11.4	9.1
Rhodium	Rh	104.1	12.1	8.6
Palladium	Pd	106.2	12.0	8.8
Osmium	Os	198.6	22.4	8.8
Iridium	Ir	196.7	22.4	8.7
Platinum	Pt	196.7	21.5	9.7

These metals always occur in the native state, and are usually associated together. The relation between

ruthenium, rhodium, and palladium, and between osmium, iridium, and platinum, is similar to that which obtains between iron, cobalt, and nickel; they are indeed very closely related to these last elements,—the resemblance in properties being greatest between iron, ruthenium, and osmium; between cobalt, rhodium, and iridium; and between nickel, palladium, and platinum. Palladium and platinum also manifest much analogy to silver and gold, and ruthenium and osmium exhibit properties which connect them with the elements molybdenum and tungsten.

They are white, or nearly white, hard metals, of high specific gravity, osmium being the heaviest of the elements; they may be melted, but only at a very high temperature with the aid of the oxyhydrogen blowpipe, with the exception of osmium, which does not melt, but volatilizes, palladium being more fusible, and rhodium, ruthenium, and iridium much less fusible, than platinum. Palladium is soluble in concentrated nitric acid, and platinum in nitrous acid, as well as in aqua-regia; the remaining metals are difficultly soluble or are insoluble in aqua-regia. They are all attacked on fusion with alkalis and potassic nitrate. Most of them possess in a high degree the property to which allusion has already been made of condensing gases on their surfaces, especially when in a finely divided state; thus, finely divided platinum at ordinary temperatures absorbs about 240 times its volume of hydrogen, and finely divided palladium at 200° C. absorbs nearly 700 times its volume of hydrogen. When heated in an atmosphere of the gas platinum and palladium also occlude hydrogen when in a compact state. The latter metal, according to Troost and Hauteville, forms a definite compound with hydrogen of the composition Pd_2H , which is further capable of absorbing hydrogen in considerable quantity; the density of the pure compound is 11.06, that of the melted metal from which it was prepared being 12, and, therefore, if it be supposed that the elements unite without condensation, that is to say, that the hydrogen has the same density as it would have if solidified in the free state, the density of solidified hydrogen is .62, or slightly higher than that of lithium. Iron, cobalt, and nickel also possess the property of occluding hydrogen, although only in a slight degree.

The following chlorides and oxides of the platinum metals are known:—

Chlorides.

Ru_2Cl_4	Ru_2Cl_6	RuCl_3
Os_2Cl_4	Os_2Cl_6	OsCl_3
...	Rh_2Cl_6	...
...	Ir_2Cl_6	IrCl_3
Pd_2Cl_4	...	PdCl_2
Pt_2Cl_4	...	PtCl_2

Oxides.

Ru_2O_3	Ru_2O_3	Ru_2O_4
Os_2O_3	Os_2O_3	Os_2O_4
Rh_2O_3	Rh_2O_3	Rh_2O_4
Ir_2O_3	Ir_2O_3	Ir_2O_4
Pd_2O_3	...	Pd_2O_4
Pt_2O_3	...	Pt_2O_4

Ruthenium absorbs oxygen at a red heat, and is converted into the oxide, Ru_2O_3 , which is its most stable oxide, whereas the dioxide is the most stable oxide of osmium. Ruthenium tetroxide, RuO_4 , is a golden-yellow crystalline substance, sparingly soluble in water, which melts at 58° C., and boils a little above 100° C.; hydrochloric acid converts it into the chloride Ru_2Cl_6 , with evolution of chlorine. The solution of this chloride is decomposed by boiling, the hydroxide $\text{Ru}_2(\text{OH})_6$ being precipitated; like ferric chloride, it is reduced to the chloride Ru_2Cl_4 by hydrogen sulphide, the colour changing from orange-yellow to blue.

Osmium, in the compact state, is slowly converted into the tetroxide, OsO_4 , when roasted in air, but the pulverulent metal obtained by reducing this oxide by hydrogen oxidizes spontaneously in the air. Osmium tetroxide is a white, crystalline, extremely volatile substance; it melts considerably below 100° C., and boils at a temperature a little above its melting point. The vapour density determination shows that it is correctly represented by the formula OsO_4 . Its vapour has an intolerably pungent odour, and is excessively poisonous. It is dissolved by water, and is a powerful oxidizing agent, but does not evolve chlorine on treatment with hydrochloric acid; most metals, even silver and mercury, excepting gold and the platinum metals, partially reduce its solution and cause the separation of osmium; it is decomposed by ammonia, being converted into the hydroxide $\text{Os}(\text{OH})_4$, with evolution of nitrogen: $3\text{OsO}_4 + 4\text{NH}_3 = 3\text{Os}(\text{OH})_4 + 2\text{N}_2$. A lower hydroxide of osmium, $\text{Os}_2(\text{OH})_4$, is known, which like ferrous hydroxide rapidly oxidizes on exposure to the air.

The tetroxides of ruthenium and osmium are apparently perfectly neutral bodies, possessing neither basic nor acid properties; the remaining oxides exhibit only feeble basic properties, and furnish unstable salts, of which very little is known. The oxides of ruthenium are readily reduced when heated in hydrogen; osmium tetroxide is reduced at a red heat, but the lower oxides of osmium are reduced by hydrogen at ordinary temperatures.

Ruthenium and osmium furnish ruthenio- and osmio-cyanides, such as $\text{K}_3\text{Ru}_2(\text{CN})_{12}$ and $\text{K}_8\text{Os}_2(\text{CN})_{12}$, isomorphous with the corresponding ferrocyanides, from which the acids $\text{H}_5\text{Ru}_2(\text{CN})_{12}$ and $\text{H}_8\text{Os}_2(\text{CN})_{12}$ may be prepared; the compounds analogous to the ferricyanides are not known. On heating the metals with potassium nitrate, compounds analogous in composition to potassium ferrate, but more stable, are formed; potassium ruthenate, K_2RuO_4 , is apparently much less stable than potassium osmate, K_2OsO_4 , which may be obtained in large rose-coloured crystals; their solutions are at once decomposed by acids, the former yielding the hydroxide $\text{Ru}_2(\text{OH})_6$ with evolution of oxygen, and the latter the hydroxide $\text{Os}(\text{OH})_4$ and osmium tetroxide.

The chlorides of ruthenium and osmium form numerous double salts, but the most important are the ruthenio- and osmio-chlorides, such as K_2RuCl_6 and K_2OsCl_6 , which are isomorphous with the corresponding platinochlorides.

Iridium and rhodium are insoluble in aqua-regia, and even when in a finely divided state are only slowly oxidized at a red heat; the most stable oxide of iridium is the dioxide, and the tendency of iridium is always to form compounds which correspond to this oxide in composition, but compounds corresponding to the oxide Rh_2O_3 are more often produced from rhodium, this being apparently its most stable oxide. The oxides of rhodium are reduced when heated in an atmosphere of hydrogen, but the oxides of iridium are reduced at ordinary temperatures. The difference between the two metals is therefore similar to that between ruthenium and osmium, which they much resemble in their general behaviour, although neither furnishes a tetroxide, and rhodium forms only one stable chloride, the hydroxide $\text{Rh}(\text{OH})_3$ being dissolved by hydrochloric acid with evolution of chlorine. Iridium tetrachloride forms double chlorides or iridiochlorides isomorphous with the corresponding platinochlorides. Like cobalt, rhodium and iridium form compounds which are not only analogous in composition to the ferricyanides, but also isomorphous with them. A number of rhodium salts corresponding to the oxide Rh_2O_3 are known, but they crystallize with difficulty; the hydroxides of iridium are soluble in acids, but no definite oxygen salts of iridium have been obtained. The hydroxides $\text{Rh}_2(\text{OH})_6$ and $\text{Ir}_2(\text{OH})_6$ manifest feeble acid

properties, dissolving in alkalis. Rhodium and iridium are precipitated from solutions of their salts by most metals, but not by silver or gold.

In many of their properties palladium and platinum more nearly resemble silver and gold than the preceding metals, just as nickel is more closely allied to copper than to cobalt and iron. Palladium is superficially oxidized at a lower temperature than silver, but its oxide is decomposed at a red heat; platinum is not in the least affected when heated in air or oxygen. The most stable compounds of palladium are the palladious compounds, a solution of palladic chloride, PdCl_4 , being decomposed when heated, with evolution of chlorine, Pd_2Cl_4 being produced; the most stable compounds of platinum, however, are those which correspond in composition to platinic chloride. Palladium, like silver, is stained by iodine, which is without action on platinum, owing to the formation of palladious iodide, which is also obtained on adding potassium iodide to a solution of a palladious salt; it is a black powder insoluble in water but soluble in ammonia, and also, like silver iodide, in a solution of potassium iodide. Both platinous and platinic chlorides, like auric chloride, readily unite with hydrochloric acid, forming chloroplutinous and chloroplatinic acids, H_2PtCl_4 and H_2PtCl_6 ; salts of these acids are produced by the combination of platinous and platinic chlorides with the chlorides of other metals. Palladious and palladic chlorides, and the corresponding chlorides of the other platinum metals, as already pointed out, form similar compounds, those which correspond in composition being in all cases isomorphous. Although platinum and palladium do not furnish compounds analogous to the ferro- or ferri-cyanides, they form a distinct series of very beautiful and highly stable salts termed platino-cyanides and palladiocyanides, which are analogous in composition to the chloroplatinates, and from which the corresponding acids may be obtained by decomposing the silver salts, for example, with hydrogen sulphide; thus:—

The palladiocyanides are isomorphous with the corresponding platino-cyanides. These salts combine with the halogens, forming compounds such as potassium platino-chlorocyanide, $\text{K}_2\text{PtCl}_2(\text{CN})_4$, which are analogous to the chloroplatinates such as K_2PtCl_6 . A somewhat similar series of bodies may be obtained from gold, *e.g.*, potassium auricyanide, $\text{KAu}(\text{CN})_4$, and potassium aurichlorocyanide, $\text{KAuCl}_2(\text{CN})_2$.

The oxides and hydroxides of platinum and palladium are somewhat more stable than the silver and gold compounds, but are entirely decomposed on ignition; they dissolve in acids, but the resulting salts have little stability, although they are considerably more stable than those of gold. The hydroxides appear all to possess acid properties, platinic hydroxide dissolving readily in solutions of alkalis, forming metallic derivatives which may be obtained in crystals. Platinic hydroxide, like auric hydroxide, is converted into a fulminating compound by the action of ammonia.

Cobalt and the platinum metals are especially characterized by the readiness with which they enter into reaction with ammonia, forming salts of cobalt and platinum bases, which are often extremely complex in composition. Thus, a solution of platinous chloride in warm, moderately strong ammonia, concentrated by evaporation, on cooling deposits yellow crystals of platinodiammonium chloride, $\text{PtN}_4\text{H}_{12}\text{Cl}_2$, H_2O ; by treating a solution of this salt with silver sulphate it is converted into the sulphate $\text{PtN}_4\text{H}_{12}(\text{SO}_4)_2$, from which the corresponding hydroxide $\text{PtN}_4\text{H}_{12}(\text{OH})_2$ may be procured by adding to the solution the equivalent quantity of barium hydroxide. Platinodiammonium hydroxide may

be obtained in crystals; it is a powerfully alkaline, caustic substance, and, according to Thomsen, its heat of neutralization is as great as that of the alkalis and the hydroxides of barium, strontium, and calcium. When platinodiammonium hydroxide is heated as long as it gives off ammonia and water, it is converted into platinodiammonium oxide $\text{PtN}_2\text{H}_6\text{O}$, from which salts such as platinodiammonium chloride, $\text{PtN}_2\text{H}_6\text{Cl}_2$, may be prepared by the action of acids; on passing chlorine into water in which the latter is suspended it is converted into chloroplatinodiammonium chloride, $\text{PtCl}_2\text{N}_2\text{H}_6\text{Cl}_2$.

The relation of these compounds to platinous chloride and to one another may be expressed by the following formulæ:—

Similarly, when a solution of cobaltous chloride in ammonia is exposed to the air, the liquid assumes first a brown and then a red colour, and if the reddened liquid is mixed with hydrochloric acid a brick-red precipitate is produced; by recrystallizing this from hot water containing hydrochloric acid it is obtained in beautiful ruby-red crystals of the composition $\text{Co}_2\text{N}_{10}\text{H}_{30}\text{Cl}_6$. The relation of this compound, which is termed purpureocobaltic chloride, to cobaltous and cobaltic chlorides may be expressed as follows:—

Nickel and copper appear to form similar compounds, but they are mostly very soluble and far less complex, these elements having little or no tendency to function as hexads.

TITANIUM—ZIRCONIUM—TIN.

Name.	Symbol.	At. wt.	Sp. gr.	At. vol.
Titanium	T	48	4.5	21.9
Zirconium	Zr	90	6.0	36.0
Tin	Sn	117.8	7.3	16.1

Titanium and zirconium are closely related to silicon, and, therefore, to carbon, and occupy an intermediate position between these elements and the true metals. Titanium and tin, however, are more nearly related than either titanium and zirconium or tin and zirconium, zirconium more closely resembling silicon, especially in the properties of its oxide.

Titanium and zirconium apparently resemble silicon closely in their physical properties, and exist both in the amorphous and crystalline state. In the amorphous state they burn with great brilliancy when heated to redness in oxygen, and they take fire when heated to redness in chlorine; titanium also unites directly with nitrogen at high temperatures, and it is stated forms the three nitrides Ti_3N_2 , Ti_3N_4 , TiN_2 . Titanium is said to be soluble in warm hydrochloric acid, but zirconium is only slowly attacked by ordinary acids, although it readily dissolves even in cold hydrofluoric acid. Crystalline zirconium is very hard, and resembles antimony in colour, lustre, and brittleness; it is less fusible than silicon.

Tin is a soft, very malleable, white metal, with a tinge of yellow, and is a tolerably good conductor of electricity, titanium and zirconium being non-conductors of electricity. It fuses at about 230°C . It scarcely tarnishes at ordinary temperatures, but at a red heat it rapidly oxidizes, and readily decomposes water. It is only slowly dissolved by

warm hydrochloric acid, which converts it into stannous chloride, Sn_2Cl_4 , but is rapidly acted on by moderately concentrated nitric acid; chlorine acts readily on the melted metal, converting it into stannic chloride, SnCl_4 . Two chlorides of titanium are known, Ti_2Cl_6 and TiCl_3 , but only one chloride of zirconium, ZrCl_4 . Titanium and tin tetrachlorides are colourless liquids, which boil respectively at 135° and 115° C.; their lower chlorides are solids, and are powerful reducing agents. Zirconium chloride is a white, crystalline solid; its vapour density corresponds with the formula ZrCl_4 . When titanium and tin tetrachlorides are mixed with a small quantity of water, much heat is developed, and they dissolve, probably forming chlorhydrins; but a large quantity of water causes their conversion into the corresponding hydroxides, which separate as white gelatinous precipitates. Zirconium chloride is dissolved even by a large quantity of water, but the hydroxide $\text{Zr}(\text{OH})_4$ separates as a gelatinous, bulky, white precipitate on the addition of alkalis.

Titanium, zirconium, and tin tetrafluoride unite with metallic fluorides, forming crystalline salts which correspond in composition to the silicofluorides or fluosilicates (p. 522), with which they are isomorphous; thus:—

Titanic oxide, TiO_2 , has a reddish-brown colour; stannic oxide, SnO_2 , is white or yellowish-white, but assumes a transient dark yellow or brown colour when heated; zirconic oxide, ZrO_2 , is white. They may be obtained in crystals which are isomorphous. Zirconic oxide is infusible, and titanite oxide melts only at the heat of the oxyhydrogen blowpipe; stannic oxide is somewhat more fusible, although very difficult to fuse. Titanic oxide is reduced by charcoal at a white heat, and stannic oxide at a full red heat; zirconic oxide, however, appears entirely to resist reduction; by ignition with charcoal in an atmosphere of chlorine they are converted into the corresponding chlorides. After ignition they are insoluble in acids, except concentrated sulphuric acid; they are dissolved on fusion with alkalis. By dissolving the oxides or the corresponding hydroxides in acids, salts such as stannic sulphate, $\text{Sn}(\text{SO}_4)_2$, are produced; the titanium and tin salts are so unstable, however, that their solutions are decomposed by boiling; the zirconium salts are somewhat more stable. Stannic hydroxide readily dissolves in alkaline solutions, but titanite and zirconic hydroxides are insoluble. The salts which are formed from the hydroxides or oxides by the action of alkalis are mostly analogous to the silicates of the form M_2SiO_3 ; thus:—

When tin is heated with concentrated nitric acid it is converted into white, insoluble, metastannic acid; the air-dry substance has the composition $\text{Sn}_5\text{O}_{10} \cdot 10\text{H}_2\text{O}$, but on drying at 100° C. it is converted into the compound $\text{H}_{10}\text{Sn}_5\text{O}_{15}$; metastannic acid has feeble acid properties, and furnishes salts which all correspond in composition to potassium metastannate, $\text{K}_2\text{H}_3\text{S}_5\text{O}_{15}$. On boiling a solution of titanite hydroxide in hydrochloric acid an apparently similar compound is precipitated.

Stannous hydroxide, $\text{Sn}_2(\text{OH})_4$, like stannic hydroxide, exhibits both basic and acid properties, dissolving in acids and also in alkalis; it gradually absorbs oxygen on exposure to the air. When a solution of titanite hydroxide in hydrochloric acid is digested with metallic copper, it becomes violet-blue, and on the addition of an alkali a dark brown precipitate separates, which probably is the hydroxide corresponding to the chloride Ti_2Cl_6 . Tin is the only

element of this group which may be precipitated as sulphide by hydrogen sulphide.

VANADIUM—ARSENIC—NIOBIMUM—ANTIMONY—
TANTALUM—BISMUTH.

Name.	Symbol.	At. wt.	Sp. gr.	At. vol.
Vanadium	V	51.2	5.5	9.3
Arsenic	As	74.9	5.7	13.9
Niobium	Nb	94	(?) 6.3	14.9
Antimony	Sb	122	6.7	18.1
Tantalum	Ta	182	(?) 10.8	16.8
Bismuth	Bi	207.5	9.8	21.1

These elements belong to the same group as nitrogen and phosphorus, but the relation between them is in a marked degree periodic, the resemblance being greatest in many respects between arsenic, antimony, and bismuth, and between vanadium, niobium, and tantalum. Vanadium is the only member of the group, excepting niobium and, perhaps, tantalum, which furnishes coloured compounds, and in this respect resembles titanium and chromium, to both of which it is about equally related. Relationship may also be traced between arsenic and selenium; between niobium and zirconium, and niobium and molybdenum; between antimony and tin, and antimony and tellurium; and between tantalum and tungsten.

The following chlorides and oxides of the elements of this group are known:—

Chlorides.

	(?) NCl_3		
	PCl_3		PCl_5
V_2Cl_4	V_2Cl_5	(?) V_2Cl_3	...

Arsenic, antimony, and bismuth are readily reduced from their oxides, but the oxides of vanadium, niobium, and tantalum are not reduced to the metallic state by ignition with charcoal; vanadium may be obtained by the reduction of its dichloride in hydrogen at a bright-red heat. Arsenic has a brilliant, dark steel-grey lustre; antimony has a bluish-white, and bismuth a reddish-white colour, they are hard, and extremely brittle, and bad conductors of electricity. Arsenic begins to volatilize at 180° C. without fusing; antimony fuses at about 450° C., and bismuth at about 265° C. They are but little altered on exposure to the air at ordinary temperatures, but readily oxidize when heated. They are readily acted upon by moderately concentrated nitric acid, but are only very slowly dissolved by boiling hydrochloric acid.

Vanadium has been obtained as a whitish-grey powder which under the microscope appears as a brilliant, crystalline, metallic mass possessing a silver-white lustre. It does not oxidize at ordinary temperatures, but when heated in air it rapidly absorbs oxygen, and is finally converted into the pentoxide. It is not attacked by boiling hydrochloric acid, but nitric acid of all strengths readily dissolves it. It is converted into a mononitride when heated in nitrogen gas.

Niobium and tantalum have been obtained only in an impure state as black powders. Like vanadium, these

elements have a great tendency to unite with nitrogen. Vanadium dichloride crystallizes in apple-green coloured plates, and vanadium trichloride forms peach-blossom coloured tables; vanadium tetrachloride is a reddish-brown liquid, which boils at 154° C. An oxychloride of vanadium, VOCl_3 , corresponding to phosphorus oxychloride, POCl_3 , is also known; it is a yellow liquid, which boils at 126° C. The vapour density of the tetrachloride, according to Roscoe, corresponds with the formula VCl_4 , but as it is resolved into the trichloride and free chlorine on boiling, and even undergoes the same decomposition at ordinary temperatures, it may be doubted whether the density observed was really that of the tetrachloride, and not that of a mixture of a lower chloride and chlorine, especially as from the analogy which vanadium presents to chromium the formula V_2Cl_8 appears to be more probable than the simpler formula.

The vanadium chlorides are dissolved and decomposed by water, the tetrachloride forming a blue, the trichloride a green, the dichloride a lavender-coloured, and the oxychloride a yellow liquid; the solution of the dichloride is a most powerful reducing agent, and the solutions of the tri- and tetra-chloride also exhibit reducing properties, owing to the tendency of the dissolved compounds to combine with oxygen to form vanadic acid.

Vanadium pentoxide or vanadic anhydride, V_2O_5 , corresponds in composition and properties to phosphoric anhydride; it has a brownish-red colour, and fuses at a red heat; it dissolves sparingly in water, forming a yellow, strongly acid solution of vanadic acid. By the combination of vanadic anhydride with basic oxides in various proportions salts corresponding to the three series of phosphates, as well as salts of a more complex character, are obtained; thus:—

Sodium metaphosphate, NaPO_3	Sodium metavanadate, NaVO_3
„ orthophosphate, Na_3PO_4	„ orthovanadate, Na_3VO_4
„ pyrophosphate, $\text{Na}_4\text{P}_2\text{O}_7$	„ pyrovanadate, $\text{Na}_4\text{V}_2\text{O}_7$

Isomorphism has been observed between several corresponding phosphates and vanadates. The tetroxide and trioxide of vanadium also possess feeble acid properties and unite with basic oxides. The vanadium oxides dissolve in acids, mostly forming salts such as the sulphate $\text{V}_2\text{O}_5(\text{SO}_4)_2$, in which the hydrogen of the acid is displaced by the radicle VO; the formation of salts of this kind is characteristic of all the metalloids included in this group, and apparently of the metalloids generally. A solution of vanadium pentoxide in sulphuric acid, which is red, becomes blue on treatment with sulphurous acid or hydrogen sulphide, the salt of the pentoxide being reduced to a salt of the tetroxide; by the aid of magnesium the reduction may be carried a stage further, and a salt of the trioxide is formed, the solution becoming green; and if zinc, cadmium, or sodium amalgam is employed, the solution finally becomes lavender-coloured, and contains a salt of the dioxide.

Arsenic trichloride, AsCl_3 , the only known chloride of arsenic, is a heavy, colourless, oily liquid, which boils at 132° C.; it is dissolved by water, probably as a chlorhydrin, as its solution in the smallest possible quantity of water deposits after some days crystals of the composition $\text{AsCl}(\text{OH})_2$.

Antimony trichloride is a crystalline compound which boils at 223° C.; its vapour density corresponds with the formula SbCl_3 . Antimony pentachloride, SbCl_5 , is a heavy, yellowish liquid, which cannot be distilled without decomposition. These chlorides are dissolved by hydrochloric acid or a small quantity of water, but a large quantity of water converts the trichloride into an insoluble oxychloride, SbOCl , and the pentachloride into a compound which corresponds in composition to pyrophosphoric acid,

viz., $\text{H}_4\text{Sb}_2\text{O}_7$. No oxychloride of arsenic or antimony corresponding to phosphorus oxychloride is known, but a crystalline antimony sulphochloride, SbSCl_3 , exists.

Bismuth trichloride is a very fusible, volatile, deliquescent, colourless compound; its vapour density corresponds with the formula BiCl_3 ; water converts it into an insoluble oxychloride, BiOCl ; when heated in hydrogen it furnishes an unstable dichloride, Bi_2Cl_4 .

Niobium pentachloride, NbCl_5 , is a yellow, easily fusible, crystalline substance, which boils at 240° C.; niobium oxychloride, NbOCl_3 , is a white, infusible, but volatile, crystalline compound. The formulæ of these bodies have been established by the determination of their vapour densities; both are decomposed by water. The solution of niobium chloride in hydrochloric acid becomes blue when a plate of zinc is immersed in it. Tantalum pentachloride is a yellow, fusible, crystalline substance, which boils at about 242° C.; its vapour density corresponds with the formula TaCl_5 ; it is decomposed by water.

Both oxides of arsenic are white; the trioxide sublimes at about 200° C. without fusing; the pentoxide, when suddenly heated to redness, fuses and is decomposed into the trioxide and oxygen. The vapour density of the trioxide corresponds with the formula As_2O_3 . Arsenic trioxide is sparingly soluble in cold water, more readily in hot water, and freely in hot hydrochloric acid; the aqueous solution reddens litmus. The pentoxide is deliquescent and easily soluble in water, forming a solution of arsenic acid, H_3AsO_4 ; on evaporating the solution, however, even at ordinary temperatures, crystals of an acid corresponding in composition to pyrophosphoric acid, $\text{H}_4\text{As}_2\text{O}_7$, are obtained, which is converted into the pentoxide when heated at about 260° C. Arsenic acid furnishes a series of salts analogous in composition to and isomorphous with the corresponding phosphates. Arsenic trioxide is almost destitute of basic properties, and the salts formed by its union with basic oxides are not very stable, so that it differs greatly from the corresponding oxide of phosphorus; thermochemical investigation confirms this conclusion. Thus, on inspection of the following table, which shows the amounts of heat which are developed on adding sodium hydroxide solution to solutions of the acids of phosphorus and arsenic, it will be evident that, whereas the behaviour of arsenic acid is similar to that of phosphoric acid, the behaviour of a solution of arsenic trioxide is altogether different from that of a solution of phosphorus trioxide (phosphorous acid), the molecule of arsenic trioxide regarded as As_2O_3 , like boron oxide, evidently existing in solution as a dibasic acid; it is not known whether the molecular composition of phosphorus trioxide is correctly represented by the formula P_2O_3 , and whether therefore the difference between the phosphorus and arsenic compounds is to be referred to the existence of a difference similar to that exhibited by the formulæ P_2O_3 and As_2O_3 .

NaOH.	PO_2H .	PO_2H_2 .	PO_3H_2 .	PO_4H_2 .	AsO_4H_2 .	$\text{P}_2\text{O}_7\text{H}_4$.	As_2O_7 .
$\frac{1}{2}$ mol.	7,100	7,700	7,430	7,330	7,360
1 „	14,380	15,160	14,830	14,830	14,990	14,380	7,360
2 „		15,270	28,370	27,080	27,580	28,640	13,780

4 „				52,740	15,070
6 „				35,280	37,400	54,480	15,560

It will be evident also on comparing the following table with that on p. 518 that much less heat is developed in

the formation of the arsenic compounds than in the formation of the corresponding phosphorus compounds:—

Reaction.	Units of heat developed.	Remarks.
As_2O_3	154,580	Formation of the solid compounds.
As_2O_5	219,380	
$\text{As}_2\text{O}_5, \text{H}_2\text{O}$	215,030	
$\text{As}_2\text{O}_3, \text{AsI}_3$	225,380	Formation of the compounds in aqueous solution.
$\text{As}_2\text{O}_3, \text{AsI}_3$	147,930	
$\text{As}_2\text{O}_3, \text{H}_2\text{O}, \text{AsI}_3$	215,230	
$\text{As}_2\text{O}_3, \text{O}_2$	64,800	Oxidation of the trioxide when dry, and in solution.
$\text{As}_2\text{O}_3, \text{AsI}_3, \text{O}_2$	78,350	
$\text{As}_2\text{O}_3, 3\text{H}_2\text{O}$	6,800	Dissolution of the trioxide and pentoxide and of arsenic acid in water.
$\text{As}_2\text{O}_5, \text{AsI}_3$	6,000	
$\text{As}_2\text{O}_5, \text{AsI}_3$	-7,550	
$\text{As}_2\text{O}_5, \text{H}_2\text{O}, \text{AsI}_3$	-400	

The oxides of antimony are white or yellowish; the trioxide is fusible and volatile, and is partly converted into the tetroxide when heated in air; the tetroxide is infusible, and unalterable by heat; the pentoxide is converted into the tetroxide at a red heat. The vapour density of the trioxide has not been determined, but as it may be obtained in crystals isomorphous with those of arsenic trioxide its formula is probably Sb_2O_3 . The oxides of antimony all exhibit feeble acid properties, dissolving in alkalis, but the salts mostly have little stability; the most stable salts apparently are those which correspond to the potassium salt of the formula $\text{K}_3\text{Sb}_2\text{O}_{11}$. The oxides of antimony are soluble in hydrochloric and concentrated sulphuric acids; the trioxide may thus be converted into the sulphate, $\text{Sb}_2(\text{SO}_4)_3$, which is decomposed by water into an acid and a basic salt.

The bismuth oxides are yellow or brown, and are devoid of acid properties, but they dissolve in acids; the pentoxide is decomposed and converted into the tetroxide when heated to about 220°C ., and the latter is reduced to the trioxide at a somewhat higher temperature. Bismuth sulphate, $\text{Bi}_2(\text{SO}_4)_3$, like antimony sulphate, is decomposed by water into an acid and a basic salt.

On boiling a solution of acid potassium tartrate, $\text{HKC}_4\text{H}_4\text{O}_6$, with antimony trioxide the so-called tartar emetic ($\text{SbO})\text{KC}_4\text{H}_4\text{O}_6$, is formed, the oxygenated radicle SbO displacing an atom of hydrogen in the potassium tartrate; corresponding arsenic and bismuth compounds are formed in a similar manner.

Niobium and tantalum pentoxides are white and infusible; they do not volatilize; after ignition they are insoluble in all acids, but dissolve on fusion with alkalis. They exhibit marked acid properties, combining with basic oxides in various proportions. The hydrated oxides obtained on decomposing the chlorides by water are acid to litmus, and are soluble in hydrochloric and hydrofluoric acids. The fluorides of niobium and tantalum, and niobium oxyfluoride, readily form double salts with other fluorides, which in many cases are isomorphous with certain titanium, zirconium, tin, and tungsten compounds which do not exactly correspond to them in composition, but in which apparently fluorine and oxygen displace one another isomorphously; thus, the following pairs of compounds are isomorphous:—

Arsenic and antimony, like phosphorus and nitrogen, form gaseous trihydrides, AsH_3 and SbH_3 , and arsenic is said to furnish also a solid dihydride, As_2H_4 . Arsine and stibine, AsH_3 and SbH_3 , are formed whenever hydrogen is evolved in presence of an arsenic or antimony compound; they are extremely unstable compounds, especially the latter, and are entirely devoid of basic properties. The

corresponding compounds of arsenic and antimony with positive hydrocarbon radicles, however, like the analogous nitrogen and phosphorus compounds, are far more stable and combine readily with other elements. Thus, triethylamine, $\text{N}(\text{C}_2\text{H}_5)_3$, and triethylphosphine, $\text{P}(\text{C}_2\text{H}_5)_3$, combine with acids, forming salts corresponding to the ammonium salts such as the chloride $\text{PH}(\text{C}_2\text{H}_5)_3\text{Cl}$; the triethylphosphonium salts, moreover, are stable in presence of water, which at once decomposes phosphonium iodide. Triethylstibine, $\text{Sb}(\text{C}_2\text{H}_5)_3$, decomposes hydrochloric acid with evolution of hydrogen, forming $\text{Sb}(\text{C}_2\text{H}_5)_2\text{Cl}$; trimethylarsine, however, does not react with acids, but with chlorine forms the compound $\text{As}(\text{CH}_3)_3\text{Cl}_2$, the existence of which furnishes a proof that arsenic may function as a pentad element. The phosphorus, antimony, and arsenic compounds absorb oxygen with great avidity, forming powerfully basic oxides such as $\text{PO}(\text{C}_2\text{H}_5)_3$. They also furnish hydroxides such as $\text{N}(\text{C}_2\text{H}_5)_4\text{OH}$, $\text{P}(\text{C}_2\text{H}_5)_4\text{OH}$, &c. (p. 575), which exhibit the closest resemblance to the alkalis; Thomson, indeed, has shown that the heat of neutralization of the hydroxide $\text{N}(\text{CH}_3)_4\text{OH}$ is equal to that of the alkalis. The existence of these hydroxides, and their behaviour, afford the strongest reason for believing that a solution of ammonia at least partially consists of ammonium hydroxide, NH_4OH (p. 510).

MOLYBDENUM—TUNGSTEN—URANIUM.

Name.	Symbol.	At. wt.	Sp. gr.	At. vol.
Molybdenum	Mo	95.8	8.6	11.1
Tungsten	W	184	18.2	10.1
Uranium	U	(?) 180	18.4	9.8

Molybdenum and tungsten are closely related to chromium. They may be obtained by reducing their oxides at a high temperature in a stream of hydrogen. Molybdenum, after fusion, is white, and has a silvery lustre; the powder obtained by reducing tungsten trioxide has a grey colour, and strong lustre. Both are difficult of fusion, and insoluble in most acids except nitric acid; when heated in air or oxygen they are finally converted into the trioxides MoO_3 and WO_3 . They form the following chlorides and oxides:—

Molybdenum pentachloride is the highest chloride obtained by heating molybdenum in chlorine gas; it is a black, crystalline substance, which forms a colourless solution when dissolved in a considerable quantity of water; when heated in air it is converted into a colourless oxychloride, MoO_2Cl_2 ; according to Delray, its vapour density corresponds with the formula MoCl_5 . The remaining chlorides are not distinctly crystalline; the tetrachloride is brown, the trichloride red, and the dichloride yellow; the molecular formulae of these chlorides are undetermined. In an atmosphere of carbon dioxide the dichloride bears a bright red heat without melting or volatilizing, the trichloride is resolved into di- and tetrachloride, and the latter when again heated, splits up into pentachloride which sublimes, and trichloride which remains; the di- and tri-chlorides are insoluble, but the tetrachloride is readily soluble in water.

Tungsten is converted by chlorine at a moderate heat into a hexachloride, WCl_6 , which forms black-violet crystals; it melts at 275°C ., and boils at 341°C .; from the determination of its vapour density it appears that it undergoes decomposition when heated. When pure it is insoluble in water below 60°C ., but if the slightest trace

of oxychloride be present it is decomposed by water even in the cold. Tungsten pentachloride crystallizes in black, highly deliquescent needles; it melts at 248°C ., and boils at 376°C ., and its vapour density at 350°C . corresponds with the formula WCl_5 . It has already been pointed out that the existence of pentachlorides of tungsten and molybdenum, and of a vanadium tetrachloride, is apparently anomalous; at present, these chlorides, chlorine dioxide, ClO_2 , nitrogen monoxide and dioxide, and, perhaps, uranium pentachloride are the only instances known to us in which apparently an odd number of affinities are disengaged (see p. 473).

Tungsten tetrachloride is a crystalline, greyish-brown substance; when strongly heated it decomposes into the volatile pentachloride and the non-volatile dichloride, which is a loose grey powder, destitute of crystalline structure. Tungsten also forms two oxychlorides, WOCl_4 and WO_2Cl_2 ; the former is obtained in beautiful ruby-red, and the latter in yellow crystals. The formula of the monoxychloride, WOCl_4 , has been established by determining its vapour density.

Molybdenum trioxide has marked acid properties, but the remaining oxides are feebly basic; both oxides of tungsten exhibit acid functions. Solutions of molybdous salts corresponding to the oxide Mo_2O_3 are almost black, and solutions of molybdic salts corresponding to the oxide Mo_2O_4 are reddish-yellow; the molybdates are mostly white. Molybdenum trioxide, MoO_3 , melts at a red heat to a dark yellow liquid, which on cooling forms a straw-yellow mass, breaking up into crystalline scales; it is scarcely soluble in water, but dissolves in hydrochloric, nitric, and sulphuric acids. Like silica and other feebly acid oxides it combines with basic oxides in a large number of different proportions, forming molybdates. Tungsten trioxide, WO_3 , is a canary-yellow substance, insoluble in water and in most acids; it melts at a high temperature, and, like molybdenum trioxide, may be volatilized by heat; it dissolves in alkaline solutions, forming tungstates, of which a great variety may be obtained by the union of tungsten trioxide with basic oxides in various proportions. The tungstates are mostly colourless. When a hot solution of an alkaline tungstate is mixed with an acid a yellow precipitate of tungstic acid, H_2WO_4 , is obtained, which is insoluble in water, and forms insoluble salts with all metals, except the alkali metals; but by decomposing tungstates by the stronger acids at ordinary temperatures a soluble variety of the acid, called metatungstic acid, is produced, which forms soluble salts with nearly all metals.

Uranium.—The atomic weight of uranium has not yet been ascertained, and its position among the elements is therefore uncertain, especially as it does not exhibit marked analogy to any other element. The generally received atomic weight is 120, but Mendeljeff has proposed to double this; L. Meyer, however, considers that from the high specific gravity of the metal it is more probable that its atomic weight is 180, and that it occupies a position in the series near to tungsten. A redetermination of the equivalent of this element and an investigation of its compounds are much required.

Uranium is like iron in colour; it tarnishes when exposed to the air, and in the pulverulent state takes fire at a comparatively low temperature, and burns with great brilliancy, forming a green oxide, U_3O_8 ; it is dissolved by hydrochloric acid, forming a green solution, which has powerful reducing properties. The highest oxide has the composition UO_3 . Uranium forms a volatile stable tetrachloride, UCl_4 , which crystallizes in dark-green octahedra, and an unstable chloride regarded as the pentachloride, UCl_5 ; both are dissolved and decomposed by water.

When uranium, or either of its oxides, is dissolved in nitric acid, a solution of uranic nitrate is formed from which the salt may be crystallized in beautiful yellow prisms of the composition $(\text{UO}_2)(\text{NO}_3)_2, 6\text{H}_2\text{O}$; on the addition of potassium hydroxide to a solution of uranic nitrate a yellow insoluble precipitate of potassium uranate of the composition $\text{K}_2\text{U}_2\text{O}_7$ is produced. An oxychloride, UO_2Cl_2 , corresponding to the nitrate, is obtained on passing chlorine over an ignited mixture of charcoal with an oxide of uranium. In all these formulæ, $\text{U} = 240$.

LANTHANUM—CERIUM—DIDYMIUM—YTTRIUM—
ERBIUM—THORIUM.

Name.	Symbol.	At. wt.	Sp. gr.	At. vol.
Lanthanum	La	139	6.1	22.6
Cerium	Ce	141	6.7	21.0
Didymium	Di	147	6.5	22.6
Yttrium	Y	(?) 89.5
Erbium	Er	(?) 170.5
Thorium	Th	(?) 178.5	7.7	23.1

Excepting thorium, these elements are closely related in properties; their compounds are of extremely rare occurrence. Lanthanum, cerium, and didymium are always associated together, and on account of their occurrence in the mineral cerite are usually termed cerite metals; they appear to occupy a position intermediate between the alkaline earth metals and the metals of the aluminium group. The atomic weights of yttrium and erbium, the so-called gadolinite metals, have not been determined; their compounds much resemble those of the cerite metals. The atomic weight of thorium is also unknown; from the properties of its compounds, however, it is not improbable that it is a member of the aluminium group.

Lanthanum, cerium, and didymium have been obtained by the electrolysis of their chlorides. Cerium is an extremely ductile metal, resembling iron in colour and lustre; it melts more readily than silver, but much less readily than antimony. It retains its lustre for a considerable period in dry air, but takes fire much more readily than magnesium, and burns with great brilliancy. It slowly decomposes cold water, and rapidly dissolves in hydrochloric acid.

Lanthanum and didymium closely resemble cerium in their general chemical behaviour. Lanthanum is a slightly harder, less ductile metal than cerium, and appears to melt nearly at the same temperature. It readily oxidizes superficially even in dry air, although it takes fire at a much higher temperature than cerium. Didymium more closely resembles lanthanum than cerium, but has a distinct yellowish colour.

Only one oxide of lanthanum is known, namely, La_2O_3 ; it is white, and unalterable by heat, and combines directly with water, forming the hydroxide $\text{La}_2(\text{OH})_6$, which is a soft, white powder resembling calcium hydroxide. The lanthanum salts of colourless acids are all colourless.

Cerium forms the two oxides Ce_2O_3 and Ce_2O_4 . Cerous oxide, Ce_2O_3 , has a (?) greyish-blue colour, and on exposure to the air is converted into yellow ceric oxide, Ce_2O_4 . Cerous hydroxide, $\text{Ce}_2(\text{OH})_6$, precipitated from the solution of a cerous salt by an alkali, is white; on exposure to the air it is converted into a mixture of cerous carbonate and ceric hydroxide; the latter is also obtained on passing chlorine into water in which cerous hydroxide is suspended. Ceric hydroxide dissolves in hydrochloric acid with evolution of chlorine, forming a solution of cerous chloride, Ce_2Cl_6 , but it forms with sulphuric acid a brown-red solution of ceric sulphate, which is a powerful oxidizing agent. Cerous salts in solution are colourless, but a few possess a pale rose colour in the solid state.

Two oxides of didymium corresponding to the two oxides of cerium are known. The lower oxide, Dy_2O_3 , is white, and in contact with water is slowly converted into the hydroxide, $\text{Dy}(\text{OH})_3$; didymium hydroxide resembles aluminium hydroxide in appearance, but has a pale rose colour, and the salts formed by dissolving it in acids have either a pure rose or violet colour. By gently heating the oxide Dy_2O_3 in air it is converted into the higher oxide Dy_2O_4 , which has a dark brown colour; it dissolves in hydrochloric acid with evolution of chlorine, and in oxy-acids with evolution of oxygen, forming the same salts as are produced on dissolving the lower oxide.

Yttrium and erbium each form only one oxide, and like lanthanum, cerium, and didymium only one corresponding chloride. Yttrium oxide, Y_2O_3 , is white, and erbium oxide, Er_2O_3 , has a pale rose colour; the former is readily soluble in acids, even after ignition, but the latter dissolves with great difficulty. The yttrium salts are colourless; but the salts of erbium have a beautiful rose colour, and their solutions give an absorption spectrum, which is not the case with yttrium salts. When erbium oxide is strongly heated it glows with an intense green light, which in the spectroscopic exhibits a continuous spectrum intersected by a number of bright bands corresponding in position to the dark bands in the absorption spectrum of solutions of erbium salts. Didymium oxide behaves similarly, and solutions of didymium salts give an absorption spectrum by which they are readily distinguished from erbium salts.

The chlorides, nitrates, and sulphates of the cerite and gadolinite metals are readily soluble in water, but their carbonates are insoluble; the solutions of their salts all possess a sweet astringent taste. The most conclusive evidence that lanthanum, cerium, didymium, and yttrium are closely allied to the alkaline earth metals is afforded by thermochemical investigation, the amounts of heat developed on neutralizing their hydroxides being for hydrochloric acid, according to Thomsen's experiments, inferior only to that developed on neutralizing the hydroxides of the alkali and alkaline earth metals, as shown by the following examples:—

Name of Hydroxide.	Units of heat developed on neutralizing with Sulphuric acid.	Hydrochloric acid.	Difference.
Hydroxides of alkali and alkaline earth metals	31,369	27,699	3,769
Lanthanum hydroxide	27,470	25,629	2,450
Cerium	25,630	24,150	1,870
Didymium	25,720	23,930	1,740
Yttrium	25,070	23,570	1,560
Manganous	26,430	22,950	3,530
Ferrous	24,920	21,390	3,530
Calcium	23,520	20,260	3,530
Glucinum	19,160	15,640	2,460

Metallic thorium has been obtained as a dark-grey powder of the specific gravity 7.65 to 7.79, easily soluble in nitric acid, but difficultly soluble in hydrochloric acid. Its oxide, Th_2O_3 (if $\text{Th} = 178.5$), is white, and after ignition is insoluble in all acids except concentrated sulphuric acid; it appears to be destitute of acid properties as it does not expel carbon dioxide when fused with alkaline carbonates. Thorium hydroxide is precipitated from solutions of thorium salts by alkalis as a gelatinous mass, soluble in most acids, but insoluble in alkalis. Thorium chloride, Th_2Cl_6 , is a white crystalline substance, which dissolves in water with rise of temperature. Thorium sulphate, $\text{Th}_2(\text{SO}_4)_3$, is crystalline, and, like the sulphates of the cerite and gadolinite metals, is more soluble in cold than in hot water.

PERIODIC RELATIONS OF THE ELEMENTS.

The foregoing description of the elements and of some of their more important compounds will be sufficient to show that, while each element manifests certain characters which distinguish it from all others, many of the elements are more or less closely related in properties, as indeed we have already frequently had occasion to point out.

Elements which exhibit similar properties often differ in atomic weight to the same or nearly the same extent; for example, the difference between the atomic weights of potassium and rubidium is about 46, and of rubidium and cesium 47.5, since $K = 39$, $Rb = 85.2$, and $Cs = 132.7$. As these three elements are closely related in properties, rubidium differing from potassium to about the same extent that cesium differs from rubidium, we are led to suspect a connection between the atomic weight of an element and its properties, especially as with very few exceptions the elements all possess different atomic weights. Many instances of relation between atomic weight and properties, similar in character to that which obtains in the case of potassium, rubidium, and cesium, have been commented on from time to time by various chemists, but the connection between the atomic weights of the elements generally and their properties was not recognized until Mendeljeff in 1869 pointed out that the latter are periodic functions of the former. In other words, if the elements are grouped in the order of their atomic weights, it will be found that nearly the same properties recur periodically throughout the entire series. Hence the whole of the elements may be arranged in a number of groups, each group consisting of members of the same natural family following each other in the same order. The elements are arranged in this manner in the following table, although, in order to retain elements which are undoubtedly members of the same natural family in the same vertical series, a few departures from the order of atomic weights are necessary, but probably they are necessary merely because the atomic weights are incorrectly determined; thus, tellurium is placed before iodine, and cerium, iridium, and platinum before gold. If the position assigned to uranium be correct, the number at present accepted as its atomic weight is much too low.

The position of hydrogen at the head of a series of metals is in accordance with Graham's conclusion that this element possesses the characters of a metal, a conclusion which many chemists are inclined to accept on account of the striking analogies to the metals which it exhibits in its relation to the halogens, oxygen, &c. As the properties of alloys are usually similar to those of their constituent metals, whereas the compounds of metals with non-metallic elements are in most cases widely different from those of the elements which enter into their composition, the fact that Troost and Hautefeuille's sodium and potassium hydrides (sodium-hydrogen and potassium-hydrogen alloys) (p. 524) retain the metallic character of sodium and potassium

affords evidence confirmatory of the assumption that hydrogen has metallic properties.

We leave it to the reader to trace out the alteration in properties which accompanies alteration in atomic weight; but we may point out as an instance that the power to combine with other elements is subject to periodic variation; thus, the composition of the highest chlorides and oxides of the elements in the first and second horizontal series in the above table is as follows:—

Chlorides.						
LiCl	GCl ₃	BCl ₃	CCl ₄	(?) NCl ₃	OCl ₂	? Cl ₂
NaCl	MgCl ₂	Al ₂ Cl ₃	SiCl ₄	PCl ₃	SCl ₂	
Oxides.						
Li ₂ O	GO	B ₂ O ₃	CO ₂	N ₂ O ₅	O ₃	? Cl ₂ O ₃
Na ₂ O ₂	MgO	Al ₂ O ₃	SiO ₂	P ₂ O ₅	SO ₃	

The chlorides and oxides of the elements of each of the following horizontal series exhibit similar differences in composition. With very few exceptions, only the elements which are included in the same vertical series as carbon, nitrogen, oxygen, and fluorine form compounds with hydrogen, the stability of which diminishes with increase of atomic weight; but the composition of these hydrides is subject to periodic variation, as is shown by the following list:—

CH ₄	NH ₃	OH ₂	FH
SiH ₄	PH ₃	SH ₂	ClH
...	AsH ₃	SeH ₂	BrH
...	SbH ₃	TeH ₂	IH

The periodic character of the relation between the properties of the elements and their atomic weights is especially evident in their physical properties, which are more readily compared than the so-called chemical properties, as they admit of measurement, although, on account of our imperfect knowledge, comparison is at present possible only to a very limited extent. One of the few physical properties which has been determined for most of the elements is the specific gravity in the solid state; now, on comparing the specific gravities of the various elements we find that they do not increase progressively with increase of atomic weight, but that they increase and diminish periodically. Hence, as Lothar Meyer has shown, on taking the atomic volumes, or quotients of the atomic weights of the elements divided by their specific gravities in the solid state, as abscissæ, and the atomic weights as ordinates, a curve is obtained which exhibits a series of maxima and minima, viz., five maxima and five minima in the portion which includes barium and the elements of lower atomic weight. The most electro-positive elements, lithium, sodium, potassium, rubidium, and cesium form the five maxima; but with increase of atomic weight the height to which the curve rises also rapidly increases, namely, in the proportion

$$\text{Li} : \text{Na} : \text{K} : \text{Rb} : \text{Cs} = 12 : 24 : 46 : 57 : 79.$$

The remaining physical properties of the elements, so far as they are known to us, appear to be subject to similar periodic variation, but for a full discussion of the connection between the atomic weights of the elements and their properties the reader is referred to L. Meyer's work, *Die modernen Theorien der Chemie* (Breslau).

The establishment of the periodic law may truly be said to mark an era in chemical science, and we may anticipate that its application and extension will be fraught with the most important consequences. It reminds us how important above all things is the correct determination of the fundamental constants of our science—the atomic weights of the elements, about which in many cases great uncertainty prevails; it is much to be desired that this may not long remain the case. It also affords the strongest encouragement to the chemist to persevere in the search for new elements.

(H. E. A.)

ORGANIC CHEMISTRY.

As has been already explained (p. 520) it was at one time thought that certain chemical compounds were producible only through the agency of living things, and the name "organic chemistry" was in consequence conferred upon this branch of the science. The progress of discovery has, however, served to break down the barrier that was supposed to exist between those and purely inorganic compounds, since it has been found possible to build up artificially a very large number of compounds formerly regarded as essentially organic. Nor must it be forgotten that many living things elaborate compounds which can in no sense be regarded as organic—such as the silica of grasses, the carbonate of calcium secreted by molluscs, &c., and the tricalcic phosphate forming the bones of the higher animals.

Although the number of elements entering into the composition of organic compounds is comparatively small, yet these compounds far exceed inorganic bodies both in number and complexity of composition. It is indeed the vast and ever-increasing numbers of the organic compounds that render it necessary to form a separate branch of the science for their study, and not any real chemical difference between the matter forming these and mineral compounds.

Definition and Character of Organic Compounds.—Carbon is an invariable constituent of organic bodies, so that this branch of the science is sometimes defined as "the chemistry of the carbon compounds." The best chemical definition of organic compounds, however, is that proposed by Frankland, viz., "compounds the molecules of which consist of one or more atoms of carbon directly combined either with carbon, nitrogen, or hydrogen."

After carbon, the elements of most frequent occurrence in organic compounds are hydrogen, oxygen, and nitrogen. Sulphur, phosphorus, the halogens, silicon, boron, and the metals are of comparatively rare occurrence. The number of atoms entering into the composition of organic molecules is often very great—far exceeding the atoms of the most complex molecule of a mineral substance. Thus, stearin contains 173 atoms, and albumin no less than 226. Chemical bodies that are possessed of great complexity of composition are generally distinguished by the facility with which they split up under the influence of the physical forces and chemical reagents; thus organic compounds are as a class characterized by their instability.

Ultimate Analysis of Organic Compounds.

Before the formula of an organic compound can be determined, it is necessary to ascertain the amounts of its several constituents—that is to say, to make a quantitative analysis of it. The elements carbon and hydrogen being of paramount importance are generally first determined. The method employed depends upon the fact that all organic compounds undergo combustion when heated with easily reducible oxidizing substances, their carbon being oxidized to carbon dioxide and their hydrogen to water. These two products of combustion being collected in suitable apparatus and weighed, the necessary data for calculating the amounts of carbon and hydrogen are obtained. The following is a brief description of the process.

Determination of Carbon and Hydrogen.—A tube of Bohemian hard glass of about 10 or 14 millimetres internal

FIG. 1.—Combustion Tube.

a-a, pure cupric oxide; a-b, mixture of substance and CuO; b-c, rinsings from mixing wire; c-d, pure CuO; d-e, metallic copper; e-f, plug of asbestos diameter, after being scrupulously cleaned and dried, is

drawn off in the blowpipe flame so as to leave a tailed extremity of the form shown in figure 1. The open end of the tube is then held in the flame of the blowpipe till the sharp edge of the glass is rounded off. This tube, known as the *combustion tube*, is from 500 to 800 millimetres in length, according as the substance contains little or much carbon.

The substance generally employed to effect the combustion of carbon compounds is cupric oxide (CuO), and as this oxide is of a somewhat hygroscopic nature, it is necessary to dry it thoroughly before use, and then exclude it carefully from the air. Should these precautions not be observed, the oxide absorbs water from the air, and when heated in the combustion tube this water distils over and is weighed with that produced by the combustion of the substance. It is therefore found convenient in practice to have another glass tube sealed at one end and closely corked at the other for the reception of the cupric oxide. This tube is of sufficient capacity to contain enough cupric oxide to fill the combustion tube, and its diameter is such as to allow it to be introduced into the open end of the combustion tube.

The substance for analysis, after being finely powdered, is dried in a water oven at 100°C . till it ceases to lose weight, or, if decomposed by heat, in a vacuum over some water-absorbing substance, such as strong sulphuric acid or calcium chloride. When dry it is transferred to a small stoppered bottle or corked tube, sealed at one end, and of about 40 or 50 millimetres in length.

The apparatus for absorbing the carbon dioxide is a series of light glass bulbs (figs. 2 and 3) containing a solution of caustic potash (KHO) of sp. gr. 1.27, through which the gases evolved during the combustion are obliged to pass. It is customary to attach to one end of the potash bulbs a small glass tube drawn to a point at its free end, and containing a small piece of solid potash enclosed between plugs of cotton wool. This appendage is for the purpose of retaining any trace of carbon dioxide or moisture carried over from the bulbs by the escaping gases.

FIG. 2.—Liebig's Potash Bulbs.

FIG. 3.—Geissler's Potash Bulbs.

The water formed by the combustion is collected in a tube (fig. 4) filled with fragments of dried calcium chloride or pumice stone wetted with strong sulphuric acid.

The combustion tube when charged is heated in a furnace which consists essentially of a row of gas burners constructed so as to burn a mixture of coal gas and air, and thus obtain a non-luminous but very hot flame. Two forms of furnace are in common use in laboratories. In Hofmann's furnace a clay cylinder perforated by a large number of very fine holes is fitted over the end of each gas burner, thus dividing the escaping gas into a number of fine streams, and so ensuring its perfect combustion. In Griffin's furnace the burners are constructed on Buusen's principle, that is, each burner is perforated by holes at its lower end so that a mixture of gas and air escapes from its upper extremity. The combustion tube is supported on a thin iron trough lined with asbestos, the whole being enclosed by unglazed tiles.

FIG. 4.—Calcium Chloride Tube.

The cupric oxide intended for use is first heated to redness in a crucible, and transferred while still hot to its tube, wherein it is allowed to cool. When sufficiently cool the cork is withdrawn, and enough cupric oxide poured into the combustion tube to occupy about $\frac{1}{4}$ th of its length. The tube or bottle containing the dried pulverized substance having been weighed, about half a gramme is then introduced into the combustion tube, and a small quantity of cupric oxide is poured down after it. The bottle being again weighed gives the exact weight of the substance employed. The substance in the combustion tube is thoroughly mixed with cupric oxide by stirring it about with a long wire with corkscrew point.

More cupric oxide is now added till the tube is filled nearly to its open end, and a plug of freshly ignited asbestos is finally introduced. The tube is then gently tapped while in a horizontal position so as to cause a slight subsidence of the contents, thus allowing a free passage for gas throughout its whole length. The calcium chloride tube is fitted into the open end of the combustion tube by means of a tightly fitting cork or caoutchouc stopper, and the potash apparatus is attached to the calcium chloride tube by means of a short piece of caoutchouc tubing bound tightly round with thin copper wire. Both the potash bulbs and calcium chloride tube are carefully weighed before being attached. The whole apparatus as arranged for the combustion is shown in fig. 5:—

FIG. 5.—Apparatus arranged for a Combustion.

The front part of the tube is first heated to redness, and the gas burners are then gradually turned on so as to cause the slow combustion of the substance. When no more bubbles pass into the potash solution the gas burners are turned out, the point of the tail of the combustion tube is broken off, and dry air passed through the whole system to sweep out the last traces of carbon dioxide and water vapour lingering in the tube. In cases where great accuracy is required it is desirable to sweep out the combustion tube first with a current of pure oxygen and then with air. This ensures the complete oxidation of any trace of carbon that may have escaped the first combustion.
